THE PRESIDENT. — We are always glad when the many claims upon his time inseparable from this Commencement season permit us to have the President of the University with us at our annual dinner. I have but to name President Eliot.

SPEECH OF PRESIDENT ELIOT.

The interesting paper to which you have just listened suggests my first remark. The greater part of the men in this room knew some of the medical men mentioned by Dr. Da Costa who were also scholars and authors. I cannot but recall in this connection one of the most delightful scholars it has ever been my privilege to know, who on the foundation of medical training was all his life a naturalist. I speak of Jeffries Wyman, beloved in this community alike by

the naturalists, the physicians, and the men of letters. I desire to say that this combination of the medically trained man and the scholar is going to persist. With few exceptions Dr. Da Costa named only the dead; but I see in the University now two of our most eminent men whose early training and whose induction into their present callings came through the Medical School. I refer to the first cryptogamic botanist of this country, Dr. William G. Farlow, and to the first psychologist, Dr. William James. The line which Dr. Da Costa has so charmingly traced is to be prolonged. I observe, too, that the value of this early training in medicine for scholars who subsequently pursue other studies is founded in the nature of things. The training of the medical man, after all, is largely the training of the naturalist. The naturalist, by birth or by the bent of his mind, takes kindly to medical training. At the start Dr. James was not attracted to the ordinary studies of language, philosophy and literature, but came to them after he had obtained an elaborate training in natural science and medicine. I believe, therefore, that we shall see a whole series of men who win a congenial training from medicine, and then couple medical learning with a great variety of other learnings.

Dr. Da Costa said that he must be excused from treating the subject of medical education, and intimated that you might have had enough of that subject for the present. Nevertheless, I shall venture to say a little on that topic; for I know it to be a topic of perennial interest to medical practitioners. Twenty-six years ago, when the University undertook to re-organize its Medical School, the hard problem would not have been solved as well as it was—indeed, it would not have been attacked—except for the eagerness of the medical profession to urge and support fundamental changes in the School. I believe that we are now on the eve of other considerable changes in medical education,—changes forced on the schools and the profession by the enormous development of medical science within the last ten or fifteen years. It is, therefore, consoling to believe with your President that it is easier to obtain endowments for medical training when medical schools are connected with universities. We have just been illustrating that in our own University. In most departments of the University the last four years have been dry years as regards new endowments. The annual gifts have shrunk in most departments, but not so in medicine. The two most considerable gifts in the last two years are both for the endowment of medical teaching,—the Fabyan Professorship last year and the Moseley Professorship this year. The present current of benefaction tends more strongly to the endowment of medical education than in any other direction; and this I believe to be a fortunate tendency, not only for the Medical School, but for the community at large.

In another way, I believe that medical education is about to undergo a considerable change. Year before last, I think it was, I mentioned to you a topic which Dr. Shattuck has again presented to you to-day,—the probability and expediency of the union of all the biological departments of the University under one Faculty. That is not, however, the point that I want to make to-day. I want to urge on you this view: that an elementary school in medicine—and any school that asks for no more than four years' residence will necessarily be an elementary school in these days—that

an elementary school in medicine, intended for the training of the ordinary practitioner, cannot be supported at its best, cannot rise to its best level, unless it is associated with a graduate school of medicine. I do not mean by graduate school a school to which young practitioners can occasionally come to hear brief courses of lectures. I mean a school all whose instruction, including the highest laboratory teaching, is given, not in short courses, but continuously by the year,—a school to which the students give all their time for a year or years, a school where medical research is steadily prosecuted. This building of a graduate school above the undergraduate school is what has been accomplished in several American universities in the department of arts and sciences, and the effect produced on the undergraduate department has been everywhere altogether admirable. The graduate instruction indirectly raises the quality of all the undergraduate instruction. The superintendence of men whose time is mainly given to the graduate work animates all the lower work, and makes it fresher and less archaic, dealing less with the past, and more with the present and the future. I hold that in all departments of university instruction the institution of the graduate school is necessary for the maintenance of the undergraduate departments at their best; and, therefore, I hope that a graduate school will soon be added to the medical department of Harvard University.

THE PRESIDENT.—New York cannot get on without professional aid from Massachusetts and from Harvard, and we are not at our best without assistance from New York.

Last year Dr. McBurney answered our summons to a consultation. This year Dr. F. P. Kinnicutt, also a graduate of Harvard, and then of the Medical School of Columbia College, has come to help us in our perplexities. A modesty which could not prevent his becoming Professor of Clinical Medicine at Columbia and a Visiting Physician at various leading metropolitan hospitals has induced him to regard the process by which, he says, I involved him in this occasion as a sort of illicit vivisection, without anesthesia. I know by this time he has abandoned that feeling. We do not regard him as a stranger, and we cannot let him feel so towards us.

SPEECH OF DR. F. P. KINNICUTT.

GENTLEMEN OF THE HARVARD MEDICAL ALUMNI ASSOCIATION:—Permit me to thank you very warmly for your more than kind welcome. Dr. Shattuck has spoken of perplexities. You have no perplexities at Harvard: they are all left for the medical schools of other cities. Among Harvard Alumni I can never feel quite a stranger; for it was at Harvard I received my first incentive for subsequent professional work,—and not only the incentive, but the foundation on which to build. Happy should you esteem yourselves, gentlemen, that you have never wandered away from the fold, but have continued to live constantly under her influence; for I am convinced that the intellectual atmosphere, the conditions of life, which prevail about Massachusetts Bay and throughout New England, are far more conducive to the attainment of the highest kind of scientific work than the turmoil, hurry and stress which ever are associated with life on Manhattan Island. As we journey further to the South, however, all the conditions are again favorable; for I am credibly informed that the very acme of restful repose abides in that portion of our country over whose intellectual development

the great University of Pennsylvania presides. The President of Harvard University, who has preceded me, has spoken so wisely and so fully on some of the subjects that your distinguished President mentioned in his address that it would be presumptuous in me to add anything further to the subject. There is a burning question with us in New York, to which I would refer; and that is the question of the true position of clinical instruction in the four years' curriculum which is being so generally adopted by the great schools of medicine in this country. I learned last night in a long and interesting conversation with my classmate, your distinguished Professor of Clinical Medicine, Dr. F. C. Shattuck, much that was valuable in regard to the system that prevails at Harvard; and I find that we have much to learn on this point, as on many others, from you. It was really a variance of opinion on this subject — I do not speak officially, but I believe I am correct in the statement — which brought to naught the lately proposed union of two great medical schools in my adopted city under the wing of the University of the City of New York. A single individual's opinion and experience is but the contribution of a mite to the subject, and my mite is very modestly offered; but as I look back upon my own student life, with its dearth of clinical instruction, compressed into a single year or two years of the curriculum, as I regard an experience gained in twenty-five years of medical work more or less constantly associated with students, as I also regard the ever-growing tendency to specialism in medicine, I am convinced of the wisdom and necessity of combining clinical instruction with the academic teaching of the schools from the *beginning* of the student's medical education. As I have observed the students, the very best of them, as they have been graduated from our schools, especially in the last ten years, I have been impressed with the extent of their theoretical and laboratory knowledge of disease, with their comparative lack of familiarity and intimate knowledge of disease as seen at the bedside.

We must remember that the great majority of our students pass directly from the schools into the active work of their profession, while another large number almost immediately enter upon some special field of work. The former are heavily handicapped for years, if not for their professional lifetime, by the lack of a varied and extended clinical experience, which, it seems to me, it is quite possible to give them during their student life; and of the latter I maintain that they can never attain to the highest usefulness of the specialist without that intimate knowledge of internal medicine which is only gained by its study at the bedside. As to the best methods of clinical instruction, your own school affords a very brilliant example; and I would only express the opinion, in which I believe many of you will concur, that it would seem wise, to a greater extent than is now the custom, to do away with the great amphitheatre with its large classes, and bring the students into the closest possible relation with the patient in the hospital wards. That is only possible, of course, by opening hospital wards to a greater extent than now to clinical instruction. This system has been introduced very lately into some of the large hospitals in New York, I am happy to say in one with which I have the privilege of being connected, through the broad and liberal views of the board of management as to the educational function of

their institution. As many students as can be advantageously instructed at one time are permitted to pursue their studies in the wards under their teacher, and the wards are open at all times for such instruction. The system demands a division of students into classes, a far greater number of clinical instructors, and possibly more arduous work on the part of the individual; but, surely, the good results are proportionate. And in this connection the growing recognition on the part of the boards of governors and trustees of our large hospitals of their responsibilities as educators, the recognition of the fact that the educational function of the hospital holds an equal place with its care of the sick is full of promise. Gentlemen, the stern edict of your distinguished President that I should compress all that I knew about medical education into a five minutes' expression on it is extremely flattering to my powers of conciseness; and I most cheerfully obey it.

THE PRESIDENT. — You will be glad to know that there is in New York a flourishing Harvard Medical Society. Its president, one of your number, is with us again to-day, as is his custom. He can tell you how it feels to go away and come back, and whether there is any way of making a good thing still better, — Dr. John Winters Brannan of the Class of 1878.

SPEECH OF DR. JOHN WINTERS BRANNAN.

FELLOW-ALUMNI OF HARVARD: — As your Chairman has stated, it has been my custom to be present at the annual meetings of this Association, but never before in an official capacity. To-day, through his courtesy, I have the pleasure of bringing you greeting from the Harvard Medical Society of New York City. May I also testify in their name and my own to the distinguished success with which President Shattuck has administered the affairs of this Association during his term of office now closing? Our New York society may be considered as an outpost of this greater body, for three-fourths of its members at least are also members of this Association; and I am sure that the remaining one-fourth will promptly enroll themselves now that your President has called attention to the fact that we are bone of one bone and flesh of one flesh, all owing allegiance to one Alma Mater, Harvard University. The object of the Harvard Medical Society of New York is the promotion of the scientific and social interests of its members, as well as the cultivation of the Harvard spirit in the metropolis. All graduates of the Harvard Medical School who reside in the city are eligible to membership. A large proportion of the members are also Alumni of Harvard College. Yale College also sends a large contingent; and the Yale men are included among the most active of the city, second to none in their recognition of the benefits they have received from the university training of Harvard. Although organized some six years ago, it is only during the present year that our proceedings have been published in the medical journals. I fancy that the keen professional eye of your President caught sight of some of our recent productions, and in this way he became aware of our existence. Perhaps some of you may be interested to know how the Harvard Medical Alumnus gets on in New York. I have here a list of members of the society, forty in number. Of these at least twenty are connected with the staffs of the various hospitals of the city. Fifteen or more

form part of the teaching force of the different medical schools, some holding places of the first rank. One of our number, whose modesty will not permit my mentioning his name, was chosen last week to be the Professor of Gynecology in the recently reorganized and strengthened Bellevue Medical College. It appears, then, that the training of the Harvard Medical School stands a man in good stead when brought into the fierce competition of the metropolis. When I received President Shattuck's kind letter, I found myself in the position of the man who said he was sure he had good blood in him, and could resist many things, but could not resist temptation. I do not here refer to your President's suggestion that I should speak of the Harvard medical men in New York, but rather to the fact that I found that I had something to say which could hardly be included within that field. However, as my subject is closely related to that of medical education—a subject which is always in order before this Association—I have thought that I might venture to bring it before you. During the past ten years the advisability of shortening the college course at Cambridge, so that the graduates of the academic department might enter the professional schools at an earlier age, has been frequently under discussion. Two years ago, in this room, President Eliot stated that he had long been in favor of cutting down the undergraduate course for all students to three years; and I have been informed that the college Faculty has recently voted, though by but a small majority, in favor of this measure. I believe, however, that it has always been understood that the reduction of the college course was solely for the benefit of those students that were to enter upon professional study. It has never been suggested that four years is too long a period to be spent at Cambridge by those whose studies end with the attainment of the degree of Bachelor of Arts, even though that degree is obtained at a somewhat later age than in former years. In fact, there is every reason, on the other hand, why the man who proposes to go into business when he leaves Cambridge should not be deprived of any of the years of study which have always been allotted to a liberal education. His professional brother, with the lengthening of the courses in law and medicine, is giving more time to intellectual training than ever before. This, then, would hardly seem the time to lessen the value and significance of the degree of A.B., which represents the end of the education of a large proportion of college students.

I have taken for granted that we are all agreed that the eight years which are now required to complete the college and medical courses is too long a period. One effect of the present condition of things is shown in the reports of the Dean of the Medical School from which it appears that the percentage of college graduates in the entering classes of the school had diminished from 53 per cent. in 1884 to 28 per cent. in 1892. The Dean further finds that there is a large and increasing number of students in every entering class who have received a certain amount of collegiate training, but have left college without taking a degree. This view of the Dean of the Medical School is confirmed by a study of the occupations chosen by the students graduating from the college during these same years. According to the class reports over 44 per cent. of the Class of 1884 chose the

professions of either law or medicine. This percentage diminished steadily throughout the succeeding years, until in 1892 only about 30 per cent. entered these professions.

What shall be done to meet this difficulty? The simplest and the most natural plan would be to allow the student at the end of his Junior year to elect the studies of the first year of his professional school, and to grant him his bachelor's degree at the end of that year at the same time with those of his class who have remained in the college. He will then have performed the four years' work for his college degree, and at the same time have completed one year of his professional course. This simple measure has been suggested before. In fact, the college Faculty has considered it, but decided against it. So far as I know, the chief, if not the only, objection urged is that it is not fitting that one and the same year of study should be offered as a part of the requirements for two different degrees. It is maintained that the year in question should form part either of the college course or of the professional course, not of both. But in reply it may be said that the studies of the first year in the professional school are at least the equal in severity of the studies required of the Senior in college. There is, therefore, no lowering of the value of the A.B. degree nor any injustice worked to those students who complete their fourth year in college and then enter upon mercantile pursuits. On the other hand, it cannot be denied that the student has actually completed one year of his professional studies, and is entitled to credit therefor. The mere fact that that same year has already been counted as a year of his college course should not outweigh the great advantage of saving to the student a year of valuable time. The elective system has been so greatly developed at Cambridge that this measure might well be considered simply as a further extension of the same system. The object that we all have so strongly at heart could thus be attained without any shock whatever to those accustomed to the old order of things which has come down to us from our fathers. I would therefore respectfully recommend that the governing bodies at Cambridge authorize some such announcement as the following in the next issue of the Catalogue of the University: "The first year courses in the Law School, the Medical School, and the Graduate School are open as electives to Seniors in the college. These courses will qualify for advanced standing in these schools, and will also be counted for the degree of Bachelor of Arts."

Should the above plan be found to work well in practice with students entering the Harvard professional schools, I should favor extending the privilege so that Harvard College students who enter professional schools of equal standing with those at Harvard—perhaps I may here mention Johns Hopkins, Columbia, Pennsylvania and Jefferson—may be granted their college degrees in like manner on presenting proof of completion of their first year in those schools. In this manner no injustice would be done to those students who deem it well to study their profession in the cities in which they intend to practise, and Harvard would be free from the appearance of endeavoring to foster her own professional schools at the expense of those of other universities.

THE PRESIDENT. — You have to-day, gentlemen, for the first time, a graduating class as your guests. The class is a comparatively small one, having been nipped by the early

frost of the fourth year and by the winnowing hand of the examiner. But I understand, on the disinterested authority of the Dean of the School, that its survivors are more than usually learned, and that some of its members have broken the records in total percentages. Thirty-nine per cent. graduate with degrees *cum laude*, and one with a total percentage of 92.05, — a remarkable performance. I will ask the Marshal of the Class, Dr. Fred Maurice Spalding, of Cambridge, to say a few words for the Medical School Class of 1897. May they all make good Alumni!

SPEECH OF DR. FRED M. SPALDING.

After enjoying such a feast of good things, as has been our privilege this afternoon, I shall simply give to you a few facts in regard to our class which I think may be of general interest. We started out four years ago with a membership of 135. As your President has just told you, by the careful use of the pruning-knife, — and, I hope, through the operation of that great law, the survival of the fittest, — our graduating class to-morrow numbers but 71, — a trifle more than half of our original number. During our four years together our number has only once been reduced by death. Our entrance class was a smaller one than usual. The reason for this is perhaps hard to tell. It may possibly be explained in part by the fact of our entering just when the hard times were beginning to be severely felt, and also the change from the three to the four years' course may have kept some away. The percentage of men in our class holding college degrees was about four per cent. less than in the classes immediately adjoining ours: the percentage of men, however, holding Harvard degrees was one per cent. higher. So much for quantity. Now what can I say for quality? I don't suppose there ever was so fine a class as ours. If some of you could only have heard the words of praise which reached our ears as our professors were bidding us farewell at the end of their respective years you certainly would have thought that we were quite nonpareil. And I might say that, if any of you wish a real good recommendation of our class as a whole, if you will simply call on Dr. Councilman, I know that he will be only too glad to give you one.

The members of our class, especially those who had any aspiration toward a surgical appointment at the Massachusetts General Hospital, always held the class that graduated last year in a certain amount of awe and veneration. When their *cum laude* list was posted with thirty-five names, we realized at once that it was a record-breaker. As far as actual numbers go, it certainly was; yet, relatively, our class with twenty-nine *cum laudes* comes within three-tenths of one per cent. of equalling their record.

Socially, we have been divided more or less into cliques, as would naturally happen in a professional school where both college and non-college men come together; yet throughout our entire course there has never been the least evidence of any friction.

The members in the Boylston Medical Society spent a very profitable year under the efficient presidency of Dr. Henry Jackson. At the end of our year of active membership a first and second prize were awarded for the best papers presented during the year. To Mr. Burrows, of the City Hospital, was awarded the first prize for a paper on leucocytosis in convulsions; to Mr. Larrabee, of the City Hospital, was awarded the second prize for a paper on the sterilization of catgut. Both papers showed a very commendable amount of good original work.

The class this year has adopted the cap and gown belonging to the candidate for the degree of doctor of medicine, according to what is known as the American code of gowns. This code is in use in several of the colleges and universities of the country. Each degree has its own distinctive gown, — distinctive either in the color of the trimming or in the style of its cut. Our gowns are to be trimmed with green and black velvet, green being the medical color, — a very suggestive color, and perhaps not an entirely inappropriate one. I sincerely hope that our adopting this gown this year will prove a stepping-stone toward the future adoption throughout the University of this code. I believe that we should do everything that we can to make our Commencement exercises more interesting and impressive.

And now, gentlemen, it only remains for me on behalf of the graduating class to express to you our appreciation and thanks for your kind and generous hospitality this afternoon, to tell Dr. Da Costa and the other speakers with how much pleasure and profit we have listened to their words of wisdom; and we want you all to feel assured that whatever we can do to advance the cause of medicine, to uphold the honor of our Alma Mater, or to further the best interests of this Association, will be done, heart and soul, by each one of us.

THE PRESIDENT. — Before parting, I must present to you your new President, an old friend and an old teacher, Dr. David W. Cheever.

SPEECH OF DR. DAVID W. CHEEVER.

BROTHER ALUMNI OF THE HARVARD MEDICAL SCHOOL: — We have been together a great many years as fellow workers, students, and teachers; and I almost wish the afternoon were longer, so that I might have time to express to you how deeply I feel the honor which you have done me — in fact, a sort of final honor to my teaching career — in electing me to preside over your society for the next three years. That satisfaction, however, is very much tempered by the feeling that I shall find it difficult to fill the place of my predecessors, who have done so much to bring your Association up to its present level. You have had but two Presidents, and it is due to them largely that this Association has reached its present prosperity. I feel I owe you something for having elected me an Overseer of Harvard College. I went into the running, so to speak, as a dark horse. Having been turned down one year, I naturally felt some reluctance at putting forward my name again; but, having been solicited to do so, I was elected by the votes of those who had votes to give. I consider you all my constituents. You all ought to have had votes, because, if you had, I have no doubt I should have received them all.

DR. J. M. DA COSTA, of Philadelphia, was present, and was called upon by the President for a few remarks. His address was published on page 221 of the JOURNAL of September 2d.

EFFORTS TO ABATE THE SPITTING-NUISANCE IN JERSEY CITY. — The Jersey City Board of Health has passed an ordinance, making expectoration on the floors or platforms of trolley- or horse-cars or public conveyances of any kind punishable by the imposition of a \$10 fine.

THE BRITISH MEDICAL ASSOCIATION AT MONTREAL.

SECTION OF GENERAL MEDICINE.

FIRST DAY.

THE meeting opened Wednesday morning, September 1st, with an address of general import by DR. STEPHEN MACKENZIE, of London, President of this Section.

DR. JAMES STEWART, of Montreal, read a paper on

ARTHRITIS DEFORMANS.

This common affection is known under the names of "rheumatoid arthritis," "arthritis deformans," and "osteo-arthritis." It often succeeds attacks of acute or subacute rheumatism, and indeed follows some of the infectious diseases, especially gonorrhea. Dr. Stewart had notes of 40 cases; quite a proportion gave a previous history of gonorrhea. In some cases the exciting cause seems to have been cold and wet; five out of 40 cases. In some, worry appeared to be a factor, 15 per cent.

Rheumatoid arthritis bears a considerable resemblance to joint affections in certain organic diseases of the spinal cord, as tabes and syringo-myelia, and may be due to some functional or organic affection of the cord. He, however, finds no good ground for the belief that it is induced by changes in the nervous system. The joint affections of these diseases are, however, not at all identical with rheumatoid arthritis. There is muscular atrophy in rheumatoid arthritis, but it is not like that of anterior sclerosis, and can be explained as a consequence of the mal-nutrition accompanying the disease. Besides in many cases of chronic deforming arthritis the cord has been examined after death and no palpable lesions found, either in the cord or in the nerves. There is no apparent causal relation between the disease and tuberculosis except that the lowered resistance which attends tuberculosis may be favorable to the arthritic disease.

There is a more probable relationship to acute or subacute rheumatism. In 30 per cent. of all cases the onset was like that of acute or subacute rheumatism. But the difference is in their sequels. True acute or subacute rheumatism gets well without marked joint changes; in rheumatoid arthritis the disease goes on to distinct lesions and deformities of the joints.

Clinical types of the disease are by no means constant and there is no sharp dividing line between certain cases of chronic rheumatism and the earlier stages of rheumatoid arthritis. There are all grades, from mere stiffness of the affected joints to the formation of new bony tissue and hyperplasia and eburnation of the cartilages.

As to the alleged connection between this disease and infection, it may be said that as yet there is no proof of a bacteriological origin. The acute and subacute forms, however, have all the clinical characters of an infectious disease.

Treatment.—This affection is most rebellious to therapeutic measures. In the reader's experience, superheated air baths have done the most good. The Scotch douche, dry heat (rather than moist) is advised.

He had treated twenty cases in the Royal Victoria Hospital by the partial, superheated air baths; in all

the relief of all the symptoms was most marked. There is an increase in the mobility of the joints after a few baths.

DR. SINGLETON SMITH was inclined to believe in the infectious origin of this disease. The arthritis is due to something besides neuropathic states, or tuberculosis or syphilis. The wasting of the muscles is incident to the amyotrophic influence of acute disease. The fact that in so many cases there is a previous history of gonorrhea gives us a clue which may profitably be followed out.

DR. LINDSAY, of Belfast, said that his experience in the treatment of this disease in England led him still to favor the old view rather than the microbic or neuropathic. He believed that there is a direct relation between rheumatoid arthritis and ordinary rheumatism. He has followed cases where chronic rheumatism has developed into rheumatoid arthritis. The etiology is generally the same: cold, exposure, poverty, privation, errors of diet, etc. But the treatment is somewhat different; the ordinary anti-rheumatic remedies are not efficacious. He has found no benefit from any thing but cod-liver oil and tonics and liberal diet.

DR. WILLIAM OSLER said that his experience had led him to support the neuropathic theory of this disease.

DR. JACOBI would have been glad had Dr. Stewart defined rheumatism, and told what he meant by rheumatoid arthritis. There is no disease which we can properly call rheumatism except acute articular rheumatism or rheumatic fever. In rheumatism proper we have to do with the synovial membrane only. In rheumatoid arthritis we have to do with the cartilages and bones. The cartilages are absorbed, there is bony proliferation, there is eburnation. True rheumatic affections have nothing to do with destruction of cartilages. He believes treatment directed against the nervous debility, the constitutional state, does the most good. He especially recommends the treatment by arsenic in increasing doses for months. He has seen some good results from this and from nothing else.

DR. J. C. WILSON, of Philadelphia, also thought that the term rheumatism should be confined to acute articular rheumatism. As for the affection which is the subject under discussion, it is frequent in elderly people whose nutrition is low after exposure to cold and damp, and it tends to changes in the bones and cartilages, stiffness and ankylosis. Often it seems to result from a succession of acute attacks, each adding its increment of change to its predecessor. He thinks the behavior of these attacks is like the repullulation of some microbic agency.

DR. F. C. SHATTUCK thought that we still knew nothing about the pathogeny of rheumatoid arthritis. It is still the opprobrium of medicine. He has known some cases to appear in connection with a concealed source of suppuration somewhere; and he related an interesting instance where the suppuration had taken place under a plate of teeth and improved under the proper treatment.

DR. MOREHOUSE, of London, Ontario, still adheres to the rheumatic theory of causation; only in treating the disease he finds that tonics do the most good. Iron, quinine, arsenic and cod-liver oil have in his practice been most beneficial.

DR. GRAHAM, of Toronto, spoke of the points of

diagnosis from gout, but thought that we were all in the dark as to the nature of rheumatoid arthritis. We must bear in mind that the diagnostic criteria of rheumatoid arthritis are the osteo-cartilaginous changes. Clinically it is certainly difficult to differentiate from chronic rheumatism. He does not however believe chronic to be identical with acute rheumatism. He has found much benefit from the arsenical treatment, but these patients never get well.

DR. T. D. GRIFFITHS believes chronic rheumatoid arthritis to be due to a development of certain constitutional conditions, and to be merely a symptom, — just as eczema is a symptom of lowered nutrition, nervous shock, indigestion, gout, etc. It is more like a skin disease due to constitutional causes than an infectious disease as small-pox or even gonorrhea. It is not due to a specific poison; *the previous state is every thing*. The treatment is one of the general conditions, supporting: tonics, good diet, good hygiene.

DR. GIBNEY, of New York, regards the treatment by superheated air-baths and the subsequent forcible correction of the deformities as far the most efficacious. In the acute stages, the limb should be confined in a splint. After the exacerbation is past, a limited range of motion (within the limits of painlessness) should be permitted.

The PRESIDENT spoke of the subject as a difficult one from an etiological or diagnostic point of view. There is such a variety of joint affections, with such different causal antecedents, classed under the head of rheumatoid arthritis. It is not rheumatism, it is not gout. He likes the name osteo-arthritis; this moreover does not commit us to any theory of causation. A leading characteristic of the disease is to develop joint-deformities. Any disease that gets well without changes in the joints we would not call arthritis deformans. He thought the disease one of debility and mal-nutrition.

DR. JAS. TYSON, of Philadelphia, read a brief paper

ON THE PROPER USE OF TERMS TO DENOTE MYOCARDIAL CHANGES.

He would reserve the term "dilatation" as applied to a well-known cardiac condition to such cases as are attended with degeneration of the muscular wall. He would substitute the word *distention* or *expansion* for *dilatation* in purely physiological cases. Instead of "hypertrophy with dilatation" where there is no structural alteration, he would say hypertrophy with distention or hypertrophy with expansion.

DR. FUSSEL, of Philadelphia, read a paper on

TWO CASES OF HEMOPHILIA,

which was followed by a very practical paper

ON ATONY OF THE RECTUM,

by DR. ATCHESON, of Galt, Ontario.

SECOND DAY.

The subject of the first part of the morning session was an address

ON THE DIETETIC TREATMENT OF DIABETICS.

by DR. ROBERT SAUNDBY of Birmingham, England.

The usual diabetic diet, with its rigid restrictions, could only be carried out by the doctor's authority and the patient's docility. Compromise was the rule, but

arrived at by the doctor's opinion being sacrificed to the exigencies of the patient. Diabetes mellitus was a clinical group, of which the causation and proper classification were still debatable. These, therefore, should not be allowed to rule our views on treatment. Glycosuria was an abnormal phenomenon, but occurred when the amount of carbo-hydrates ingested exceeds the utilizing capacity of the body. This capacity varied in different individuals, and perhaps in the same individual at different times. Those who become easily glycosuric from slight excess stood in close relation to the milder forms of diabetes. In severe diabetes glycosuria persisted even on flesh diet — a fact explained by the formation of a carbo-hydrate molecule when albumin was converted into urea. Hence in severe diabetes there was no physiological ground for persisting with strict diet in the hope of thereby removing the glycosuria. We must look to clinical results for the justification of our treatment, and must not be led too far by our prepossessions in favor of any disputed pathological doctrine. Instead of following a blind routine we should give each case as much carbo-hydrate as experience showed he could assimilate. Of carbo-hydrates it was best to give one and a half pints of milk, six ounces of baked potato, one and a half ounces of levulose, and, in mild cases, four and a half ounces of dry toast. Fat bacon should, if possible, form one meal, but diabetics appeared to absorb fat badly. Alcohol, in the absence of albuminuria, might be allowed up to four ounces daily, well diluted with mineral water, or, in mild cases, a bottle of light Moselle or Bordeaux wine, or even a pint of bitter ale. It was of great importance to prescribe definite quantities, and to test the effect of the diet by weekly body weighing, urine measurement, and sugar estimation.

This address gave method of dieting delineated in his book, the main features of which are as rigid an exclusion of carbo-hydrates as possible without damage to the nutrition and general condition of the patient, the case being very carefully watched. The discussion which followed was of the greatest interest.

DR. TYSON, of Philadelphia, said that Dr. Saundby's method was essentially his own. The exclusion of carbo-hydrates can never be complete and many patients do better on a diet not too rigid. Cases drop into two classes, the mild and the severe. In mild cases it is easy to eliminate sugar by diet; in the bad cases this cannot be done. The first form may be called glycosuria, the second is true diabetes. Dr. Tyson believes that the mild cases if left alone will develop into the grave in time. He aims in the light forms to reduce the quantity of sugar in the urine under two per cent.; the patients are then practically well. You can then allow them with safety a certain amount of carbo-hydrate. Once a month put them on a pure proteid diet for a few days, and the sugar disappears completely, then relax on diet, but not so much as to exceed two per cent. of sugar in the urine. In severe cases a rigid diet will not take out the sugar. If you give nothing but pure meat, the urine will still contain sugar in large amounts, and the presence of a large amount of sugar in the urine is harmful. The polyuria is due to sugar; as is the diabetic amblyopia, the furunculosis, etc.

Is a pure proteid diet harmful? Munsen's studies seem to indicate that an exclusive proteid diet increases diacetic acid in the urine. This is responsible

for the coma. There are other toxic substances, according to this authority, due to a breaking up of albumin. It is not, however, proved that these toxic substances do not come from the body-albumin instead of the proteids of food.

DR. TYSON first puts his patients on a rigid proteid diet to see what can be accomplished. Then he adds one article after another containing more or less starch or sugar, watching the urine, and he finally makes the diet as liberal as the individual case will permit.

DR. SIDNEY COUPLAND, of England, said that his experience had been similar to that of Dr. Saundby and that detailed by Dr. Tyson. In some cases marked benefit comes from dieting, in others the benefit is slight or *nil*. In some cases the patient rapidly gets worse after being put on diabetic diet. It is impossible to altogether exclude sugar and starch.

DR. SINGLETON SMITH, of England, spoke of the diabetes of young people as being peculiarly intractable and fatal. In these patients we cannot allow much latitude of diet. In elderly people we are obliged to give more latitude. In his own practice he tries to carry out a rigid system, determining by experiment how much carbo-hydrate in each particular case can be assimilated, and making concessions only as circumstances demand.

DR. EBENEZER DUNCAN, of Glasgow, Scotland, thought that the matter of sugar in the urine is not the chief factor of prognosis. If the diabetes be pancreatic, neither diet nor any thing else will do much good. In nervous diabetes we should restrict the diet persevering as long as nutrition does not weaken and the patient can digest the diabetic diet. We must not give way to the cravings of our patients. Dr. Jacobi, of New York, has found that some patients will not thrive on any dietetic treatment. Old people often emaciate if you drop their carbo-hydrates. In the diabetes of young people, you must withhold carbo-hydrates as much as possible. Under a proteid diet young patients live longer.

As to the question of milk, he would say from his experience that he has never seen a patient get worse to whom a moderate amount of milk was allowed. In fact, they generally improve on milk. He does not believe in Donkin's skim-milk treatment. He gives milk in any form as an adjuvant. Old persons do not do well on a strict diet; they do better on a mixed diet.

DR. LINDSAY, of Belfast, England, also spoke of the necessity of allowing elderly patients much liberty. He gives milk as an adjuvant—a quart or so a day—but does not believe in an exclusive milk diet.

DR. TYSON, of Philadelphia, said that he had had much experience with the exclusive milk treatment. In mild cases it does well; the sugar disappears. But there is no permanent advantage in this, while in severe cases the consequences are disastrous. Milk is safe along with other things. The presence and the amount of sugar in the urine is generally an index of the condition of the patient, but sometimes we have to disregard this as an index of the danger of the patient.

DR. WRIGHT, of Ottawa, was inclined to look upon glycosuria as distinct from diabetes. The former is the diabetes of elderly people. You cannot much restrict their diet.

DR. STEPHEN MACKENZIE, the President, said that the paper of Dr. Saundby was a protest against blind routine, counselling a study of the individuality of the

patient and the necessity of finding out the limitations and restrictions of diet necessary, the practitioner being guided not so much by the sugar in the urine as by the requirements of the patient. Is the patient improving in nutrition, strength, weight, in respect to thirst and other symptoms, or is he deteriorating? These are questions which the physician should constantly have before him in treating either the mild or the grave cases.

DR. SAUNDBY said, in closing, that he was far from wishing to leave the impression that he advocated latitude in diet, his point was the reverse of this. He however believed in giving his patients a diet that was well tolerated by them and not repugnant. It was necessary to allow a certain amount of carbo-hydrate. He did not object to potatoes—four to six ounces a day; the quantity of sugar in the urine is not materially augmented. The sugar seems to some extent to be assimilated. We must make the lives of these patients as tolerable as we can. What is the diet which in each case will best maintain nutrition? As to milk, he has for years added it to his dietary. One litre daily may be allowed with safety.

DR. EBENEZER DUNCAN, of Glasgow, Scotland, read a paper on

THE TREATMENT OF DIABETES BY URANIUM NITRATE.

This medicine was introduced into therapeutics by Dr. West. The reader has found that in doses of fifteen to twenty grains three times a day it markedly diminishes sugar in the urine besides alleviating all the symptoms. He thinks that it stimulates the sugar-consuming cells of the organism. Best in neurogenous diabetes.

DR. TYSON said that he had tried the remedy twenty years ago. He had derived no benefit from the smaller doses (2 to 5 grains) then used. It frequently disturbed the stomach and caused diarrhea.

DR. SAUNDBY said that he had also tried uranium nitrate in small and large doses and had seen no good come from it.

Other papers read at this session were as follows:

THE BACTERIOLOGY OF PERTUSSIS,

by DR. HENRY KOPLIK, of New York, in which he said that he had been almost uniformly successful in finding the Affanassieu bacillus;

A CASE OF CROSSED HEMIPLEGIA DUE TO INJURY OF THE PONS VAROLII,

by DR. J. E. GRAHAM, of Toronto;

THE DISAPPEARANCE OF ENDOCARDIAC MURMURS, PRESUMABLY ORGANIC,

by DR. J. H. MUSSER, of Philadelphia.

HOSPITAL CAR. — A new hospital car is being constructed for the Long Island Railroad. The car is built like an ordinary Pullman, and has the best system of springs and trucks. There are seventeen cots, and, in an emergency, hammocks may be swung from the ceiling to accommodate ten or fifteen more patients. In one end of the car there is a complete operating-room, fitted up with glass tables, and all modern surgical appliances. The car will be kept in readiness at all times, so that in case of an accident it may at once be despatched to the scene.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, SEPTEMBER 9, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE SANITARY SERVICE OF RAILWAYS AND NAVIGATION.

THERE is a meeting this week at Bruxelles, Belgium, the Second International Conference concerning the Sanitary Service of Railways and Navigation. The International Medical Congress at Moscow, the British Medical Association meeting in Montreal, and the recent meetings of the American Association for the Advancement of Science at Detroit and the British Association in Canada, have naturally drawn attention away from this second Conference at Bruxelles, which especially calls together the medical men of the navies, the mercantile marine and the railroads of the world.

The first Conference was held in 1895 at Amsterdam, September 19th-22d, inclusive. The circular sent out by the committee of organization says: "The measures taken in different countries to guarantee the physical condition of employees and their and the passengers' hygienic conditions are very different, and in many respects ineffectual. It seems, therefore, desirable to call an international conference of the medical men interested and engaged in the sanitary questions of the railroads and navigation." Prof. H. Snellen, who holds the chair of ophthalmology at the Utrecht University, was chosen as the head of the movement, and acted as President of the Conference. Some seventy gentlemen from various countries met at the Conference. Their several reports and experiences, and their discussion were published in the "Comptes rendus des Travaux de la Conference," which is now before us. This volume of some three hundred pages contains very practical reports and papers: Section I, Proofs of the Physical Condition of the Personnel; Section II, Organization of the Medical Service; Section III, Sanitary Interests of the Employees and Travellers. The interchange of experiences and the discussions were as practical as valuable. Even the

varying conditions of railroad work in different countries did not prevent a very close connection in reference to the special demands of physical condition, as shown by the interesting reports of the aurists and the ophthalmic surgeons. The necessary *international* character of the reports and discussions as to the navies and merchant marines was naturally much greater.

A report as to the United States had been asked of our townsman, Dr. B. Joy Jeffries. This he gave, and it is printed in the conference *Compte Rendu*. He was elected one of the Vice-Presidents. He has, as is well known, been engaged the past twenty years in endeavoring to obtain concurrent action of the maritime nations in the control of the physical condition of the officers and men of navies and mercantile marines. The necessity of such control being internationally agreed to is now admitted. It will be remembered that the rules and regulations of sailing, lights, signals, etc., which the Washington International Maritime Conference reported, went into effect July 1st last, as agreed by the several nations taking part. The British Medical Association Committee on the control of Mariners' Eyesight, etc., report July 17, 1897, the necessity of international action and urge that representatives be sent to the Bruxelles Conference. The Amsterdam Conference agreed to meet again in two years, by invitation, at Bruxelles, at the time of the International Exposition. Whilst not a part of the scientific work, which perhaps alone concerns us, we notice that the members and their families were well looked after and entertained, as they are no doubt being now at Bruxelles.

The programme of the Conference before us shows that there are plenty of important subjects and many distinguished men to discuss them. It also shows that during the five days' session the members will be fittingly entertained by the Belgian Government and the corporation of the city of Bruxelles. Dr. J. P. Nuel, Professor of Ophthalmology of the University of Liège, presides.

In behalf of the Conference, our townsman, Dr. Jeffries, has enlisted the interest and participation of the United States Government. The Navy has sent Surgeon J. D. Gatewood as a representative; the Army, Surgeon D. L. Huntington; and the Marine-Hospital Service, Passed-Assistant Surgeon Jos. J. Kinyoun.

We have called attention to and explained this Conference because it will bring before governments and organizations the true position and value of medical men, and encourage the latter to exercise their legitimate and much needed influence in certain fields. The Secretary-General well says in his circular: "This Congress is not alone of scientific and hygienic interest. In the medical point of view it deserves serious attention. Our *confrères* will, with eminent men of other countries, discuss their relation to the administration, and cause to be appreciated the great services which they render to the administrations and to the public."

A PHYSIOLOGICAL DETERMINATION OF MAXIMUM AND MINIMUM SCHOOL HOURS.

THE readers of educational literature must have been struck with the productiveness of the last few years in the reports of investigations of notable value, into the health of school-children, undertaken for the double purpose of ascertaining their fitness for prolonged mental exertion and for determining how they are affected by such exertion.

Inquiries of this sort have long been prosecuted in one or another form by the teachers and students of Clark University, at Worcester, and the attention excited by the statistics which were published some years ago by Dr. Warner, of Manchester, England, is still fresh in the memory.

It is, however, particularly noteworthy that our Saxon cousins in Germany, to whom study has been the breath of life, have begun to show alarm over the ill-effects of the stern cramming which seems to go on in their schools; and a number of important criticisms and comments from eminent physicians have appeared in the medical journals. The literature of the experimental investigations to which this movement has given rise has been recently reviewed by Dr. Max Brahn, of Leipzig, in a paper which is published in the *Deutsche Medicinische Wochenschrift*¹ and is commendable as a clear and concise presentation of the facts at stake.

It will perchance be long before our educators have sufficient faith in physiological methods to accept them as dictators of school customs, but it would be the folly of ignorance to treat them with contempt.

The methods followed in estimating the advent and accumulation of fatigue were either those of Kraepelin or Ebbinghaus, who tested the rate of diminution of the higher mental powers, as shown in the failing capacity to add figures, or to detect errors in spelling, etc.; or those of Griesbach or Kemsies, who sought, by the aid of special instruments, to determine changes in the sensibility of the skin, or in the strength of certain muscles, at different periods in the school day and year.

In these ways the fatigue induced by school work and the rest secured by sleep and vacation have been traced out with a good deal of accuracy, and the average capacities of children at different ages have been carefully computed, while withal, it has not been overlooked that a great amount of individualizing is necessary, both on account of varying intellectual capacity and on account of varying degrees of health.

The recommendations of the authors cited, as brought together by Dr. Brahn, are as follows:

(1) The periods which the writer calls units of study (*Lebseinheit*) should not be longer than 25 minutes for children between six and nine years old; 30 to 35 minutes for those between nine and twelve; 40 to 50 for older children. Only the higher grammar-school pupils should study uninterruptedly a longer time than this and then only under special conditions.

(2) The length of the pauses should vary in proportion to the length of the units of study, from 10 to 15 minutes and upwards. It is held to be a principle of fundamental importance that it is

not enough simply to change the character of the employment in order to get the necessary refreshment, but that a real rest is needed after every sort of mental application [including, we would add, that necessary for gymnastics].

(3) The number of hours of daily study should be from two (eventually three) for children between six and nine; three to four for children from nine to twelve; four to five for children above twelve. Afternoon hours of study should, as a rule, be abandoned.

(4) In arranging the subjects for the different hours, attention should be paid not only to pedagogic considerations, but to the relative degree of fatigue which different subjects induce. Those which call for the greatest effort, such as mathematics or number work, should come early in the day; then should follow the languages, and finally history, geography, natural history and technical branches. Gymnastics could come at the end and should not be introduced between other studies.

(5) It has been impossible, as yet, to obtain sufficient data to justify categorical statements with regard to vacations. Investigations into the rate of growth of children in the different periods of the year are much needed as a basis for conclusions on that point.

(6) More attention than heretofore should be paid to the changing needs of the years preceding puberty. The child under twelve years old needs to be stringently protected against overtaxing. The tenth and eleventh years in particular should be devoted rather to the assimilation of what has been learned before than to progress on new lines. The centre of gravity, so to speak, of the child's education, should be pushed from the years of childhood into those of puberty. It would, therefore, be desirable to have the age of seven the first public-school year and fifteen the last.

(7) Pupils ought to be separated according to their capacities. The bodily weak, the mentally backward and those predisposed to nervous ailments, should be divided into smaller sections than has been customary.

(8) All these rules, especially the last, imply the co-operation of school physicians, and those who fill these positions should have some knowledge of the elements of scientific psychology.

MEDICAL NOTES.

THE NORTHWESTERN UNIVERSITY WOMEN'S MEDICAL SCHOOL has added largely to its corps of instructors.

QUARANTINE AGAINST MONTREAL. — The health board of Ottawa has established a quarantine against trains from Montreal, because of the small-pox in the latter city.

POISONING BY CHLORATE OF POTASH. — A death from an overdose of chlorate of potash is reported from Vienna. The present case is that of a woman who took twenty-five grammes of the drug.

TEXAS FEVER IN IOWA. — Texas fever is reported to be spreading among the cattle in Southwestern Iowa. The cattlemen have become greatly alarmed and have appealed for assistance to the State authorities.

YELLOW FEVER IN MISSISSIPPI. — Yellow fever has recently appeared at Ocean Springs, Miss., a town about 56 miles from Mobile, and 84 from New Orleans. One fatal case has developed in the person of a man named Gelpi, who went to New Orleans from Ocean Springs. The New Orleans Board of Health is taking all possible precautions against the spread of the disease, and quarantine against the infected town has been declared in all the surrounding cities and States. On September 7th, three cases of

¹ No. 26, p. 422, June 21, 1897.

yellow fever were reported at Biloxi, Miss. There is at present no general exodus from New Orleans for the north; and unless the disease should, as is improbable, gain a foothold there in spite of the lateness of the season and of the efforts of the Board of Health, none is anticipated. On September 7th, there had been no new cases reported at Ocean Springs, and but one additional death.

THE FIRST QUARANTINE IN NEW YORK.—The first quarantine in the harbor of New York was established in 1737, and was due to reports that small-pox and spotted fever were raging in South Carolina.

THE PRINCESS OF WALES TRIES THE KNEIPP CURE.—It is reported that the Princess of Wales recently tried the Kneipp Cure at Woerishofen, but that one morning's walk in the wet grass resulted in such a cold that the treatment had to be abandoned.

PENCIL STERILIZERS.—The State Board of Health of Indiana has issued an order requiring all schools to be provided with pencil sterilizers and safety drinking-fountains. The former is a Russian iron oven heated by gas, gasoline, or alcohol, in which pens and pencils are to be heated daily to a temperature of 275° F.

AN EXPLOSION OF CARBIDE OF CALCIUM.—An explosion occurred recently in a laboratory at Saint Michael-de-Maurienne, where carbide of calcium was being manufactured. The building was destroyed, and one workman was killed and three others were seriously injured. Carbide of calcium, it will be remembered, is the material from which acetylene gas is produced.

A PATIENT FINED FOR LEAVING A HOSPITAL.—A patient has lately, according to the *Lancet*, been fined for leaving an English fever hospital while suffering from typhoid fever. He had been an inmate for some time and had apparently been very ill, but during his convalescence he thought he was well enough to go, and so walked out one day without saying anything to any one. Patients in general hospitals not infrequently practise this mode of departure, which probably does little harm to any one except the patient himself; but in the case of infectious hospitals things are different, for unless the patient and his clothes are properly disinfected disease may be spread to any extent.

AN EXPENSIVE BOOK.—The Pension Roll still stands as the most conspicuous figure in the long array of our heritages from the Civil War; but it has a very healthy younger relative known as "The Official History of the War of the Rebellion." This work is said to have cost the United States government nearly \$2,500,000 already, and another \$500,000 has been called for. We are told that three years more will be required for its completion, that it will consist of over 100 volumes, and will be the most expensive book ever published. We are also told, on good authority, that history *repeats* itself; but we sincerely trust that the reproductive functions of this particular history may not prove abnormally active.

Miscellany.

SUN-BONNETS FOR HORSES.

The Medical Press and Circular comments on an amusing proposal as follows:

Luton is the centre — as most people are aware — of the straw-hat making industry in Great Britain. The staple trade, dependent as it is to a great extent upon the vagaries of fashion, has many ups and downs. The latest attempt to give a fillip to its commercial activity savors not a little of the grotesque. Last week it was officially announced that the Luton Chamber of Commerce had received from the new Government Department of Commercial Intelligence several specimens of foreign-made hats for horses, sent to England by the Bordeaux British Consul who stated in an accompanying report that such hats were in general use in that district. As a proof of utility it was stated that since the introduction of such headgear the Bordeaux Tramway Company had not lost a single horse from sun-stroke, whereas their previous losses in that way averaged twelve animals yearly. The specimens forwarded were made of rush, in the shape of a wide-brimmed and high-crowned hat with holes for the horses' ears, and bound with red braid, and strings to tie under the chin.

This proceeding represents, indeed, humanitarianism run riot into stark, staring foolishness. Just now, the scientific medical man is inclined to doubt the occurrence of heat apoplexy as the direct result of the sun's rays falling upon the head, except in rare instances. Horses that fall dead in hot weather have probably been overworked and not supplied with enough water. Not even the prospect of bolstering up a decaying British industry would reconcile the average Englishman to the ridiculous spectacle of a horse rigged out by a hatter, however fitting it might appear to a nation that has actually provided its poodles with trousers. It is reported, however, on good authority, that Luton hat-manufacturers bask in the full sunshine of prosperity, notwithstanding that the straw-plait industry has been handed over almost entirely to the Chinese. It is said that the National Society for the Prevention of Cruelty to Animals has taken the matter up, we trust merely to lay it down again, unless they want to convert their society into a common laughing-stock, and to walk straight into a clever pitfall, which would be baited with a big, big gooseberry appropriately.

PLASTIC OPERATIONS ON THE THUMB.

The importance of saving the thumb for purposes of effective opposition to the fingers in complicated injuries of the hand can hardly be overestimated. A laboring-man can perhaps better afford to lose any three of the other fingers than the thumb; and a very useful hand for purposes of the rougher forms of manual labor is left if the thumb and perhaps the stump of one finger have been preserved after an accident.

Of especial interest in this connection is a paper by Nicoladoni, published in the *Wiener klinische Wochenschrift* of July 15, 1897. He describes the case of a man whose thumb was caught in machinery, and the skin of the entire member and the thenar eminence was torn off like the corresponding part of a glove. The denuded article was restored by lifting a suitably-shaped flap from the breast, which was left attached by a pedicle, folded over the thumb like the finger of a glove, and sutured in position. The hand was banded to the chest, and when the flap had become firmly attached the pedicle was cut and trimmed and sutured in position.

A very serviceable thumb resulted, the only defect

being that the linear scar which was on the palmar surface prevented more than very slight motion at the interphalangeal joint, and held the joint fixed in partial flexion. The man was perfectly able to do his work in a scythe factory. The drawing of the hand shows a thick and clumsy-looking thumb; but looks are hardly to be considered in a case of this sort when a man's ability to work is at stake.

The presence of the left nipple on the radial side of the thumb renders it a curious-looking object, and leaves no doubt as to the portion of the body from which the transplanted skin was taken.

Nicoladoni lays stress upon the importance of having a broad border of attachment for the transplanted flap, such as is furnished by the circumference of the thenar eminence, so that a plentiful supply of blood may be secured for the nourishment of the flap.

In a subsequent case in which necrosis of the skin of the thumb had been produced by the application of a strong solution of carbolic acid, but in which the thenar eminence was not involved, Nicoladoni partially denuded the thenar eminence in order to give a broad base of attachment for his glove-finger flap, and in this case also secured an excellent result. A subsequent case of necrosis from carbolic acid was similarly treated with excellent success.

Nicoladoni further describes an ingenious operation by which he proposes transplantation of a finger to replace a lost thumb by an operation performed in several stages, and also the transplantation of a piece of periosteum and bone from the tibia to take the place of the bones of the thumb, after the skin has been supplied by the method already described.

Whether these operations will be ever successfully carried out is, of course, at present a matter of doubt; but any proposed operation which gives even a chance of success in supplying the loss of this important and useful member should, if possible, be given a trial.

AN AUTOPSY IN A CASE OF INNOMINATE ANEURISM CURED BY THE INTRODUCTION OF GOLD WIRE AND ELECTROLYSIS.

D. D. STEWART, M.D., Physician to the Episcopal Hospital, Philadelphia, reports in the *British Medical Journal* for August 14th, an autopsy which he was fortunate enough to obtain on a man for whom he had over forty-one months before succeeded in completely curing of a very large innominate aneurism by the employment of electrolysis through ten feet of snarled coiled fine gold wire introduced into the sac.

The case was unfavorable in that the man was an alcoholic and syphilitic, and the subject of pronounced aortic and mitral disease, with extensive cardiac enlargement, generalized endarteritis, and chronic nephritis. The aneurism formed a large and prominent swelling at the roof of the neck. It was regarded as springing from and being limited to the innominate artery. The sac wall was of extreme thinness, and, at least externally, was unprotected by clot. This, which was apparent to the eye and touch, was further demonstrated by puncture with needles. At the time of operation the sac wall seemed on the point of bursting externally in several situations over which the skin was extremely thin and bluish.

The result of electrolysis through the introduced wire was very decided. Clot-formation, leading ap-

parently to solidification of the sac, was early manifest. The patient lived for nearly three years and a half after operation, and finally died as the result of the formation of a large thrombus in the middle cerebral artery, the result of the advanced endarteritis present. Despite the most unfavorable condition of the patient, his bad cardiac and renal disease and generalized arterial sclerosis, his having had syphilis, and being a steady spirit-drinker, the result obtained speaks strikingly in favor of this procedure as a method of treating sacculated aneurism. The sac was to be of extreme hardness, with complete consolidation and obliteration of its cavity.

At the autopsy, which was performed four hours after death, the heart was found to be dilated and hypertrophied, the aortic and mitral valves sclerosed and insufficient, and there was a distinct fusiform aneurism at the junction of the transverse and descending portions of the aorta, which throughout was the seat of extensive atheromatous degeneration:

"The sacculated [innominate] aneurism springs directly from the root of the innominate artery. The aneurismal sac is approximately the size of a fetal head at term; length, thirteen centimetres; transverse diameter, nine centimetres. The sac is completely consolidated with organized coagula in which lie the coils of wire. The consolidated sac has at its base a small *cul-de-sac*, the remains of the innominate artery. This, from the aorta, admits the little finger to a distance of four centimetres through an annular ring, sharply defined, two centimetres in diameter. The *cul-de-sac* was noted to contain in its interior a small coagulum, presumably of post-mortem formation. The sac itself was very firm and wholly solidified, and when cut into was found to be completely occupied by organized material, in the interstices of which lay the coils of fine gold wire. Brain: A large thrombus is evident in the left middle cerebral artery. Softening has occurred in the region of the corpus callosum, caudate, and lenticular nucleus, and in the internal capsule of the left side."

This cerebral thrombosis was evidently the cause of death.

"[Stewart] has now treated two cases of sacculated aneurism by the employment of electrolysis through introduced wire, and has directed the technique in a third successful case. This has naturally led him to give a good deal of attention to the subject. The result in his second successful case, the necropsy of which is here reported, and that obtained in the case treated by Dr. Hershey, of Colorado, in which the solidification of the aneurism resulted by this method, is sufficiently suggestive to engage the attention of the therapist."

The method of treating aneurism by the introduction of wire was first introduced by Moore, at the Middlesex Hospital, in 1864.¹ His case died of sepsis. Stewart thinks that in this case a great excess of wire was introduced. The cases of Loreta and Moore (both abdominal aneurisms), in which six feet and four to five feet of wire were respectively introduced, both resulted in cure. Stewart employs under strict antiseptic precautions fine silver or gold coiled wire which, after the introduction of a moderate amount, will assume snarled spiral coils which will reach the whole calibre of the sac. Failures have occurred through the use of wire which was too stiff or too bulky; and steel or iron wire will decompose, and fill the sac with a granular detritus, which may be the cause of emboli. Galvanism with a rather strong current, 40 to 80 milliampères, Stewart considers a

¹ Medico-Chirurgical Transactions, xlvii.

very important part of the treatment; for, although the presence of the wire itself may be sufficient to obstruct the blood stream sufficiently to cause thrombosis, the passage of the galvanic current through the coils is observed to cause much more rapid and firm solidification.

By galvano-puncture with needles, although firm coagula are punctured, they are of such small dimensions and engage such small portions of the sac walls, that their dissolution rather than their accretion quickly follows.

"A striking demonstration of the power of his method to promote clot-formation," writes Stewart, "is shown in my second case. In this, 10 feet of fine gold wire had been passed, and a current of 85 milliamperes employed for one and a quarter hours. Four weeks after this procedure a needle of quite large calibre was thrust into the sac to a depth of two inches in several situations, in which, at the time of operation, blood spurted at its introduction when apparently only beneath the skin. The needle in the second attempt was found to firmly engage the clot, though thrust perpendicularly up to its hilt in the sac. It could not be circumducted save with effort, and escape of even a drop of blood at any depth did not occur; nor was the needle or wire (which last had been attempted to be reinserted through the needle), when withdrawn, blood tinged. This beautifully demonstrated the apparent complete solidification of the aneurism."

The electrolytic effect of the current upon the endothelial lining of the sac is, as McEwen has demonstrated, extremely favorable to the formation of organizable white thrombi, from which vascularized fibrous tissue readily springs.

The report of the autopsy on Stewart's case is certainly an important contribution to our knowledge of the treatment of large, sacculated aneurisms.

Correspondence.

HEALTH BOARDS AND THE WIDAL TEST FOR TYPHOID FEVER.

DUBLIN, N. H., September 6, 1897.

MR. EDITOR:—Why has the Boston Board of Health done nothing to furnish facilities for the diagnosis of typhoid fever similar to those now furnished for the diagnosis of diphtheria? There is not a city of any size in the United States *except Boston* whose Board of Health is not employing the Widal serum-reaction for the diagnosis of typhoid fever as a matter of public health. New York, Chicago, Philadelphia, Baltimore, Cincinnati and other cities reported the work of their respective health boards in typhoid serum-diagnosis at the meeting of the American Medical Association last June; and Dr. M. H. Richardson and I, who reported our own private work there, were repeatedly asked why our Boston Board of Health was so behind the times. We found it difficult to defend the inertia of our city. At the recent meeting of the British Medical Association in Montreal, Dr. Richardson tells me that the situation was equally embarrassing, Boston being still the only city of any importance medically whose Board of Health has done nothing to further medical science and improve the public health in this respect. The method is no longer in the experimental stage. Over 5,000 cases are on record to show its value in diagnosis and its accuracy as a test. Prof. William H. Welch of Johns Hopkins University concludes a paper read at the Philadelphia meeting above referred to, with the following propositions:

(1) Experience has demonstrated that the method of serum diagnosis of typhoid fever is of great practical value.

(2) Provision should be made, especially by the establishment and support of municipal or State laboratories, to render generally available to practitioners the serum method of diagnosis as well as other bacteriological procedures of similar practical value.

The value of the method and the details of its application by boards of health have been worked out by other cities. Is there anything for Boston to do but to fall into line, even if we are a year behind everybody else?

Very truly yours, RICHARD C. CABOT, M.D.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING AUGUST 28, 1897.

SAWTELLE, H. W., surgeon. Granted leave of absence for thirty days from September 6, 1897. August 10, 1897.

MEAD, F. W., surgeon. Granted leave of absence for three days. August 2, 1897.

BANKS, C. E., surgeon. To proceed to Newport, R. I., for the physical examination of H. L. PECKHAM, second lieutenant, Revenue Cutter Service. August 4, 1897. Granted leave of absence for twenty-seven days from August 9, 1897.

CARMICHAEL, D. A., surgeon. Granted leave of absence for thirty days from September 15, 1897. August 6, 1897.

CARRINGTON, P. M., passed assistant surgeon. To proceed to Birmingham, Ala., for special duty and then to rejoin station, Evansville, Ind. August 11, 1897.

MCINTOSH, W. P., passed assistant surgeon. Granted leave of absence for twenty-one days from August 8, 1897. August 3, 1897.

KINYOUN, J. J., passed assistant surgeon. Granted leave of absence for five days. August 10, 1897.

PERRY, T. B., passed assistant surgeon. To rejoin station at Buffalo, N. Y., on return to Evansville, Ind., of Passed Assistant Surgeon P. M. CARRINGTON. August 11, 1897. To proceed to New Orleans, La., and report to commanding officer for duty and assignment to quarters. August 26, 1897.

VAUGHAN, G. T., passed assistant surgeon. Granted leave of absence for six days from August 30, 1897. August 27, 1897.

STONER, J. B., passed assistant surgeon. To proceed to Buffalo, N. Y., and assume command of service. August 26, 1897.

GRUBBS, S. B., assistant surgeon. To proceed to Boston, Mass., and report to commanding officer for duty and assignment to quarters. August 12, 1897.

AMERICAN PEDIATRIC SOCIETY.

INVESTIGATION OF INFANTILE SCURVY.

The American Pediatric Society is making a Collective Investigation of Infantile Scurvy as occurring in North America, and earnestly requests the co-operation of physicians, through their sending of reports of cases, whether these have already been published or not. No case will be used in such a way as to interfere with its subsequent publication by the observer. Blanks containing questions to be filled out will be furnished on application to any one of the committee named below. A final printed report of the investigation will be sent to those furnishing cases.

Address.

THE RELATION OF MENTAL DISEASES TO GENERAL MEDICINE.¹

BY EDWARD COWLES, M.D.,

Medical Superintendent, McLean Hospital, Waverley, Mass.

MR. PRESIDENT AND MEMBERS OF THE MAINE MEDICAL ASSOCIATION:—The subject upon which it is my privilege to offer you some remarks this evening is one in which I hope to interest you, although the matter presents peculiar difficulties, and, having some forbidding aspects to the general physician, it is somewhat aside from your general discussions. In the short time at my disposal, I cannot be expected to say much upon the practical details of the treatment of the different forms of insanity. But the progress in modern medicine has been so great that its new light is clearing away much of the mystery and obscurity which have surrounded mental disorders. In discussing, however briefly, "The Relation of Mental Diseases to General Medicine," I hope to give you something of practical value in showing you how these mental affections fall into line with the new principles that are coming to guide your professional labors.

In the company of physicians gathered here there are some of us who began the study of medicine in the first decade of this half century. We can remember being taught to distinguish between the sthenic and asthenic types of disease. Antiphlogistic remedies still held an important place in our therapeutics. Our fathers in the first quarter of the century, as the disciples of Rush, practised to its full extent the "depletory treatment." The second quarter-century witnessed the establishment of the scientific medicine of our day, of which Virchow, still living, was the acknowledged head. In the department of mental disease it was then, also, that Griesinger, a contemporary of Virchow, made the great advance of the age in completing the emancipation of the insane from the methods of barbarism. He established the diagnosis of diseases of the mind upon the exact basis of general medicine, and as symptomatic of pathological processes, with a more hopeful view of curability than was held under the previously prevailing idea of mysterious psychical disorders.

The alienists were leaders in the practice of the "supporting treatment" from the beginning of the century. Those of us who were students before the War of the Rebellion saw, and perhaps some of us experienced in our youth, the bleedings and the purgings, and the derivations, of the depletory theory. We were taught, however, only its waning principles and little of its practice.

How marvellous have been the changes that have brought us to the conceptions we hold to-day of the scientific principles that underlie our medical art. While the lessons of the war emphasized "the supporting treatment," and led to the new surgery of to-day, the course of this advancement illustrates the law which Herbert Spencer calls the tendency to integration of the present specialties in medical science. The basis of surgical progress, and the new principles that are revolutionizing modern medicine, are united in the newest science of bacteriology.

The earlier neurologists, working in their new de-

partment of medicine, conceived almost thirty years ago the idea of fatigue and exhaustion of functional power in the reduction of the storage of energy in nerve cells. This was Beard's conception of nervous exhaustion as "waste in excess of repair," manifested by "irritable weakness." The "supporting treatment" gained a larger and more exact significance in the "rest treatment." Here again, the alienist kept equal step in Van Deusen's priority of announcement of the theory of the condition which he called *neurasthenia*. Thus the clinical observation and treatment of mental diseases led independently and logically along the same path of progress with that of general medicine.

In the advancement of neurology of the last thirty years, the brilliant anatomical discoveries and precise localizations of nervous diseases strengthened the general demand that a definite pathological explanation should be found for all forms of disease. In general medicine the physician was expected to refer to definite structural lesions, or demonstrable physiological disorders, to explain the phenomena of each clinical form of bodily disease. There was still the too narrow conception of each organ and tissue as having its own maladies with pathological changes peculiar to itself; and the tendency still held to seek special remedies for the cure of each individual form of disease. With the improvement in the methods of microscopy there came an era of seeking for pathological findings and explanations of disease in the different minor mechanisms of the body.

While the advances just described were being made, the alienist, in the treatment of diseases of mind and brain, still had to depend upon the clinical data of general medicine. The methods of histological study did not go far enough beyond the comparatively gross anatomical determinations which permitted the localization of the effects of disease in the nervous mechanism. They were not fine enough to reveal the inner structure of nerve cells, and detect the changes corresponding to mental symptoms. In default of such explanation the alienist and his work appeared to be unprogressive and inadequate. There was, however, no lack of diligent study of mental diseases. The methods of minute observation and analysis of symptoms were pursued with the tendency to discover many new clinical forms, or subdivisions of them, to the great confusion not only of the general physician but of the alienists themselves. They had failed in the previous attempts to establish a classification of mental diseases by an explanation of them upon an etiological basis, as if post-febrile insanity, puerperal insanity, phthisical insanity or lactational insanity, and the like, presented any real differences from the phases of melancholia and mania having other exhausting antecedents.

The scientific method of the later studies did make clear one point of great value in defining the relation of heredity and of inherent defect of the nervous organization with degenerative tendencies, to those forms of mental alienation commonly known as monomania, or better, primary delusional insanity. The elucidation also of general paralysis of the insane, popularly called "softening of the brain," and its possible relation to syphilis in a large proportion of the cases, was the one successful instance of tracing a connection between a characteristic group of mental symptoms and certain definite pathological findings as belonging to a cortical disease. But while we have

¹ Delivered before the Maine Medical Association, June 3, 1897.

been becoming able to recognize the *places* of the mechanical interferences due to the lesions which cause the motor and sensory paralyses, they gave us no better explanation of the disturbances of mental function in brain cells. One great truth appears to be revealed by these studies in regard to sclerosis in the nervous system. They go to sustain the statements of Weigert and Elinger, that overwork and exhaustion may be potent causes of nervous disease, not only of a functional, but of an organic character, attended by a shrinkage and degeneration of the nerve cell and its fibre forming the neuron now recognized as the unit of structure of the nervous system. The process termed sclerosis is merely nature's process of healing by the substitution of a supporting substance within the brain and cord, to take the place of the atrophied nerve cell or fibre. The great significance of this, in relation to mental diseases, lies in the inference that anything which interferes with the maintenance of proper nutrition of the neuron, whether it be persistent overwork and exhaustion, or the effects of poisons arresting nutrition, may begin by abating power in the mental function. To this cause are due the mental symptoms which occur during the processes leading to actual organic changes.

These considerations, though presented in so bare an outline, may serve to give some idea of the relations that have existed in recent years between the conceptions of mental diseases as to their pathological basis and that of general and nervous diseases. The methods of research and of clinical investigation, that at first had done so much in revealing the pathological processes of nervous diseases, have been reaching their limitations within the last ten years. Almost absolutely nothing could be expected of them as to the physical basis of mental diseases. Indeed, it is true to-day that insanity, as to its mode of causation through pathological processes, remains for the greater part a mystery.

But the relation of mental to general diseases, on clinical lines, has continued to be a close one; and the former have been finding their way along those lines to new relations, and to some share in the great progress of modern medical science. This unity in the treatment of mental diseases, or in psychiatry, with the clinical methods of general medicine, can be made clearer by a brief mention of the therapeutics of insanity, in prevalent use during the last ten or twenty years. Then I shall try to point out some of the essential features of the new principles in medicine and to indicate how they throw new light upon mental diseases. Thus the contrast can be made between the old and the new conceptions of underlying principles which promise to make these special diseases more intelligible to the general physician.

The best advances in psychiatry, along clinical lines, have generally been made by the application of medical common-sense. Taking the principles we have to work with, those embodied in the "supporting treatment" for example, there is no mystery in the application of them to mental disease. There is no specific treatment for the large class of functional mental disorders that tend to recovery, because generally symptomatic only of reduced nervous energy and disappearing with the restoration of the general health. Consider also another class of mental affections of which I have spoken, those typified by the monomanias, otherwise called primary delusional insanity. When we recog-

nize them as the expression of constitutional nervous weakness, the indication is plain why they offer only a bad prognosis. General paralysis, also mentioned as a definite brain disease, is, for that reason, hopeless.

Now let us consider further the functional or symptomatic mental disorders forming the majority of mental cases, presenting the acute and curable forms that may occur either in sound people or in the inherently weak, and known clinically as melancholia and mania. We may regard these forms as the depressive and excited phases of one disease or morbid condition, which, for want of a better name, may be termed ordinary insanity. Whether or not we hold that these forms are but manifestations of nervous *asthenia* or its equivalent, the fact remains that for many years these conditions have been practically treated upon the common-sense plan of the "supporting treatment." Putting aside the difficulties you meet, as general practitioners, in the management of these cases, the necessity for the protection of the suicidal and the control of the maniacal, and there being provided the safe custody of a hospital, or of a private house turned into one, and looking at the strict therapeutics of your case, the indications are very plain. The specialist first properly protects and guards his patient. Then, upon investigation for all physical signs, he meets their symptoms under the common rules. There are commonly few objective symptoms, except that if there is, for example, constipation, nervous dyspepsia, neuralgia, or any of the train of neuroses, they are palliated by the means any physician would employ. But this would be done with the understanding that they are all likely to be only expressions of the prime condition which calls first for elimination, nutrition, rest and sleep; then for mental and physical hygiene; and then, as convalescence progresses, for proper exercise, entertainment, occupation and gradual restoration to self-responsibility.

In dealing clinically with these neurasthenic conditions, the advanced alienists were quick to recognize the first contributions of the principles of bacterial diseases. They were already practising upon the physiological fact that the expenditure of energy in nerve cells is attended by waste products that must be eliminated, their toxic effects being inferred to be accompaniments of nervous exhaustion. The theory of auto-intoxication then illuminated their work at once with explanation. Though there was as yet no demonstration of the pathological process, the inference was strictly in accordance with physiological laws. After this the discoveries in physiological chemistry, the work of Bouchard in pathological chemistry and its application by the French alienists and others to the conception of the relation of infectious diseases to insanity, together with the evidences of a like relation to nervous diseases, were all logical sequences of the principle of modern medicine newly discovered by Pasteur, our greatest benefactor in modern times.

This brief mention of some of the most salient particulars of scientific progress in different departments of medicine may serve to indicate the position to which psychiatry has come in the last ten years; and that what it has really accomplished in the way of advancement has been in concert with the clinical side of general medicine, rather than through the discovery of pathological changes peculiar to the nervous system itself. The reason why this is so, is well stated by Van Gieson. He says, "that much of the present obscurity in the pathogenesis of nervous and, especially,

of mental diseases, is largely to be explained by the very simple fact, that the brain and the rest of the nervous system has been studied altogether too much as something apart from the rest of the body — as something beyond the jurisdiction of the laws of the great fundamental pathological processes which operate on the whole organism."²

What is required for a better understanding of the pathological basis of insanity is the correlation of the nervous system with other tissues and organs in the body in the study of the effects of the few fundamental pathological processes which underlie mental and nervous, as well as diseases in general. We shall see that the mental symptoms of the ordinary acute forms of mental disease present, though by a less intense and slower process, a strong analogy to the mental derangement and confusion attendant upon active exhausting influences, such as starvation and mental shock, and to the commonly observed delirium of typhoid and other febrile affections.

We may now examine the new principles that have already in so short a time revolutionized our conceptions of general pathology, to see what new light they bring to the elucidation of mental diseases. We may see, also, how this specialty of mental maladies, as well as that of nervous diseases as a whole, may be brought into common alliance with general medicine. The student of psychiatry can but feel that he is at the beginning of a new epoch in mental medicine.

There are two chief additions to our knowledge, which have given us this great promise. For my present purpose, they may be stated in the order of their discovery, or application to our study. (1) The discovery of the principles which explain the effects of toxic influences upon the physiological activities, nutrition and structure of the organic tissues in the body. (2) The new methods of investigating the anatomy and physiology of the nervous system.

(1) The toxic causation of diseases. There is need here for only the briefest statement of these new principles now so well known. The accepted fact that some diseases are due to the presence in the body of some form of poison, whether it be the product of bacteria, or arises from excretions or secretions produced by some of the organs of the body, or from an abnormal condition of the blood, the general fact affords the foundation for the complete revolution of our conceptions of general pathology.

One group of these toxic influences are the substances received from *without the body*, such as active poisons, infective germs or their products. While these include such poisons as lead, arsenic, mercury, alcohol, etc., their like pathological effects upon the nervous system align them with the bacterial infections, and the poisons associated with the development of bacteria within the body. As we now know them, diphtheria, rabies and tetanus are examples of the poisonous effects of the bacteria themselves, and of their products, causing toxemia and producing the symptoms of the disease.

The other principal group is included in the auto-intoxications. In these the first effects of the intoxicants are due to poisons formed *within the body* as the products of chemical agencies in disordered physiological activities. While it is difficult to classify these self-produced poisons, their nature is indicated by men-

tioning some of them. The waste products of normal exercise, which show their effects in the feelings of fatigue and somnolence, are injurious to the organism and require free elimination. Disorders in the chemical processes of nutrition, or of the reduction of waste material to the end — products duly formed for excretion, yield the poisonous substances attendant upon indigestion, or irregularities in the action of the liver and kidneys. While we know little as yet of the sources, and conditions of production, of the poisons in the group of diseases like gout and rheumatisms, we do not hesitate to explain them as due to auto-intoxication, and we recognize their common association, not only with symptoms of bodily disease but with nervous and mental disorders. There can be no doubt of the important relation of these toxic disorders to neurasthenia as the initial condition of many diseases, both of the general organism and of the nervous system.

Another class of conditions must not be omitted here, in which there is toxemia, due to the absence of certain normal secretions. An example of this is the remarkable disease myxedema, associated with its strange disorders of nutrition. One of the brilliant triumphs of modern medicine is seen in the successful treatment of this disease with thyroid extract, when by supplying the deficient material the patient recovers, not only from long existing physical effects of the disease but the mental symptoms disappear. Of equal interest and significance is the recognition of the toxic effects of an excess of the thyroid secretion.

These meagre references to the advances that are being made in many lines of medical research will serve to show how these newly-discovered pathological principles are bringing order and unity into our conceptions of disease processes.

(2) The reconstruction of our knowledge of the nervous system in the past ten years, through the new methods of microscopical research discovered by Golgi, and developed by Cajal and others, has given us a precise and definite understanding of neural construction. The whole nervous system is now known to be built up of a vast number of elementary neurons; each one of these, independent of all others, and representing a single nerve cell with its protoplasmic processes and nerve fibre, constitutes an individual neuron. Although presenting many minor variations in form, this is the law of all. The grouping together of these in anatomical and physiological relations affords a clear conception of the nervous mechanism. Along with these discoveries in regard to the *external* forms of the neurons, we have the other great discoveries through the methods of Hodge, Ehrlich and Nissl, revealing the *inner* construction of the nerve cell. The chemical reactions obtained by new processes of staining show the physiological changes attendant upon fatigue and exhaustion in the normal cell by its shrinkage, and recovery after rest. The changes due to morbid influences are also demonstrable by these new discoveries in cellular pathology. These new methods of investigation have opened a multitude of lines of research, which are full of interest and promise.

The present results of this great progress in scientific medicine may be summed up from Van Gieson's recent description in a remarkable and comprehensive discussion of their relation to mental diseases.³ The

² The Toxic Basis of Neural Diseases: New York State Hospital Bulletin, vol. i, p. 408.

³ New York State Hospital Bulletin, vol. i, p. 417.

experimental effects, upon the ganglion cells of animals, of such poisons as arsenic, lead, mercury and alcohol, were found to be essentially the same for all these poisons and were phases of an *acute parenchymatous degeneration*. Similar studies of the internal changes in the nerve cell, due to bacterial toxemias, such as typhoid fever and diphtheria, showed effects of essentially the same type. Again, extensive observation in experimental and human rabies showed identical cellular lesions to those of the bacterial poisons. The inference was, therefore, that parenchymatous changes of uniform character are produced in nerve cells by poisons of different natures,—that an acute or chronic type of these internal changes corresponds to an acute or intense action of a poison, or to the gradual, intermittent or persistent effects of a poison of milder intensity. It further appeared that these cell changes were manifestations of a single, great fundamental pathological process; namely, acute parenchymatous degeneration of the nervous system. The great significance of this is still further extended by the inference that this same pathological process is elicited by the action of the same poisons in other organs in the body as well as the nervous system. These conclusions were sustained by observations in uremia, sunstroke, and experimental thyropraxia.⁴

It is of great interest and importance, in regard to the origin of mental diseases, to note here an explanation which is afforded through the growing belief that most of the processes of disease in general are due to toxic substances in one form or another. It cannot be disputed that the application of this toxic theory of disease must include the nervous system, and that the brain is involved like any other organ of the body, in these general toxic or somatic diseases. It thus follows that many of the insanities are but the expression of the later disturbance of the functions of the brain, dependent upon changes in the nerve cells produced by the action of toxic substances.⁵ This statement need not exclude many affections primarily of a psychic origin, for the reason that purely mental and emotional causes may initiate disorder in physiological processes so that the inefficient exercise of certain functions may start the train of toxic sequences. The interesting consideration referred to in this connection is the obvious fact that the dependence of changes in the nervous system upon general somatic diseases must be often masked. It may be a long time between the occurrence of some general bodily disease, or the initial touch of the morbid cause, and the appearance of the mental or nervous symptoms due to the damage wrought on the brain by the toxic substances associated with the acute general illness or other causation. Nothing is more certain than the frequently recurring clinical fact that in cases presenting mental symptoms practically identical, the function-reducing cause is obvious in some, doubtful in others, and not rarely altogether lost to recognition. For this reason we are in danger of seeking too much for explanation of nervous and mental symptoms as due to pathological processes originating in the nervous system, or in a disease belonging to it alone. It is more conservative to first seek a more general explanation.

It may be objected that we are but at the beginning of being able to differentiate the pathological changes in the internal structure of nerve cells, and therefore that we may expect, through better methods of study, to find different appearances corresponding to different causes.

This objection is certainly a valid one, but however far we may ever go in differentiating internal cell changes, the primary fact must remain that any failure to perfect the building up of cell contents to form the material of energy must show itself in a reduction of functional power. This is a conservative position to stand upon, and we may hope to make our distinctions in the ordinary forms of mental disease more safely when we are better able to recognize the changes in their physical basis. The alienist should not cease to study the variations of mental symptoms in even ordinary cases that appear practically identical; but, at the same time, it is a very reasonable expectation that we are approaching the most satisfactory basis of our work in the broad conception of a few simple and general pathological processes, which commonly reduce functional energy in acute or chronic degrees; and that mental symptoms largely vary through differences which pertain to normal individuals, with due allowance for the inherent defects and instability of the neuropathic. This applies to the so-called function or symptomatic mental disorders, and indicates a method for their systematic study; it is not intended to exclude the possibility of enlarging the class of mental diseases that have characteristic pathological lesions, of which general paralysis is an example.

While the demonstrations of the principles here outlined, including the observations of other investigators, are still limited, the conclusions rest so strongly upon analogy and logical inference from extensive clinical data that they are generally accepted as probably true.

The researches in physiological chemistry and the investigations of the various forms of auto-intoxication in their origin and effects in disorders of different organs of the body are building up evidences of a general truth. This truth is that, however various in origin, and different in their chemical and toxic character, they produce like effects, in progressive degrees, namely, irritability, blunting and paralysis of function, and degeneration. It is of immense importance to our new understanding of nervous and mental disease that we can bring such a conclusion to bear upon their origin. While it may continue to be practically impossible to separate and identify these complex chemical poisons, it is claimed that we have attained, nevertheless, the position that their presence can now be determined microscopically by their effects upon the nerve cells, and by the associated nervous and mental symptoms. This conclusion is of great practical value, because it is when we have knowledge of the causes and conditions of morbid processes that we can successfully seek and apply intelligent and effective prophylaxis and curative treatment.

Now let us assume that we have set forth, though in a fragmentary fashion, the new principles of a broad general pathology, on the basis of the wide influence of toxic elements in the production of morbid processes in the organism. Let us assume, also, that in all the cell structure of the organs and tissues of the body, the common effect of these poisons is essentially one process, attended by irritation, weakening, reduction of functional power, often shown alike by mental depres-

⁴ A case of acute insanity associated with definite changes in the internal structure of the nerve cells, occurring at the McLean Hospital, was reported by Dr. Hoch, February 17, 1897. See Boston Medical and Surgical Journal, August 19, 1897, p. 182.

⁵ Loc. cit., p. 469.

sion and excitement. The process, continuing, goes on to degeneration in various degrees, until recuperative force is lost, and destruction supervenes with the possible substitution of sclerotic tissues.

Assuming these things, the conclusion of this discussion may be devoted to an application of these principles to common experiences in our practice. Our logical position is that when we approach a case of nervous or mental disease, or one in which the nervous system is especially involved, we have to deal with an individual whose neurons, in some part, are in a condition of disorder or disease. This means the observation of symptoms in the patient of mechanical or chemical effects upon the neuron elements of his nervous system. Normal activity implies the recurrence of physiological fatigue and its symptoms as accompaniments of daily toil, with the breaking down of cell contents in work, the elimination of toxic waste products, and restoration by nutrition, rest and sleep.

The history of the case may reveal an excess of waste of nervous energy over its repair. This means a greater or less persistent fatigue or exhaustion of functional power in the neuron, which includes the power to assimilate nourishment. Thus exhaustion, once initiated in some degree, begets diminished nutrition and more relative exhaustion, if the cause continues. In many cases the balance continuously turns but slightly the wrong way, and the process is a long one; again, the exhausting influences are great and abrupt in their effect, even to mental shock. Thus we note the sequence of overwork and exhaustion. The toxic manifestations appear as effects of excessive waste products, there is deficient elimination from the overworked nerve cells, toxic materials enter the blood, nervous dyspepsia and constipation betray defective innervation, and in turn contribute to further disorders of nutrition. The same relative conditions may occur in the indolent and sedentary, through deficient elimination and lack of physiological exercise necessary to normal physiological growth. The mental signs, sometimes without any bodily signs, are those of loss of spirits or depression, attendant upon a vague sense of bodily ill-being, diminished power to apply the attention, and a tendency to worry unduly. These common symptoms of neurasthenia, that are so familiar to us, are striking expressions of ill-nourished and disordered neurons. The logical treatment of such condition is elimination to reduce the toxic conditions, rest and nutrition.

Here is the prolific soil from which all nervous diseases may spring. Mental disorders beginning in such symptoms require only increase in degree to become pronounced melancholia; and graver degrees and effects of exhausting causes induce the more serious intellectual derangement in mania. The evolution of the groups of symptoms in these acute mental diseases, the common history of exhausting causes, the process of gradual convalescence as from a neurasthenic state, are all clearly explained on the basis of their being functional and curable conditions with toxic elements in their production. The course of development of the symptoms is in the order of overwork, exhaustion, auto-intoxication.

We have to consider that insanity may follow all forms of acute disease, or from the many forms of toxemia which may affect the nutrition of the neurons, and that whatever the antecedent that induces the condition of nervous exhaustion, whether overwork, in-

fectious fevers or nutritional disorders, the same groups of mental symptoms oftenest appear. No explanation satisfies these clinical appearances so well as to ascribe the mental phenomena to one essential fact: reduction of functional power in the neurons. This accords with the pathological finding that the changes produced within the nerve cell appear to be essentially alike from poisons of widely different natures.

The terms "nervous exhaustion" and "exhausting influences" relate, in their strictest sense, to a condition of the neuron elements induced by excess of expenditure of energy over repair, along with which there is a toxic element the production and elimination of which is physiological and necessary. But the same relative condition is produced when there is small expenditure and deficient elimination, in respect to the mere vegetative processes, in persons unnaturally inactive, when the neural repair is, for any reason, still less than the waste. The fat neurasthenics described by Weir Mitchell belong to this class. In this case there may appear clinically the same reduction of functional power, nervous and mental, as in the first instance. Again, it may happen to persons of both classes that poisons from without, or produced within the body, may conflict with the physiological principle that the inner contents of a nerve cell are chemically built up into complex compounds, which constitute the material of energy and break down when the cell does its work. Any toxic cause, in the blood or tissues, that impairs or arrests this process, whether chemically or otherwise, must beget the same effect of a corresponding reduction of functional forces, and may produce like symptoms.

In like manner "nutrition" and "nutritional disorders" relate, in the end, to the chemical processes within the cell. It is not solely a matter of gain or loss of body weight; while this is a true criterion in most cases, there are many in which it is reasonable to conclude that the process of "nutrition" may go on well, even to its final stage in the nerve cell, and there become imperfect or arrested as by a chemical fault, perhaps due to some toxic element. We certainly see examples of loss of weight, sometimes rapid, not sufficiently accounted for by any apparent fault of digestion, when an abundance of food is taken that would ordinarily fatten. In the broader conception of all function-reducing factors as essentially "exhausting influences" we are enabled to extend the demonstrations of the phenomena of fatigue to explain the remarkable uniformity in groups of mental symptoms, for example, when arising from most varied causes, or in the absence of any apparent cause.

It is interesting to consider that epoch-making, and remarkable in simplicity and clearness, as are these new explanations of disease processes, they are still the fulfilment of expectations that have been long entertained. As Van Gieson remarks, our belief that the large majority of diseases are due to the circulation of poisons within the body is a result to which we have gradually come. Before we had sufficient pathological evidence, it was naturally thought that the continued fevers, the exanthemata, syphilis, tuberculosis, rabies, tetanus, hydrophobia, and in fact all the infectious and contagious diseases, were the manifestations of poisons entering from without or elaborated within the body. Bacteriology has shown the true relation of micro-organisms to some of these diseases. Functional disorders, degenerations, necroses and

scleroses, are explained as one general pathological process from diverse causes, though presenting different appearances in different tissues. The brilliant example of diphtheria, and its now familiar antitoxin treatment, gives us the clue to new and scientific modes of treatment of a rapidly widening range of disease.

This brings us exactly to the thought to which I have wished to lead you. The treatment of mental diseases is being brought more closely than ever to common ground with general diseases. In your practice you may no longer look upon insanity as peculiarly a pathological mystery. The acute and so-called functional forms certainly are not so. For general paralysis you find, as diagnostic, certain definite sensory and motor signs along with characteristic groupings of mental symptoms. Moreover, its most rational explanation is as having an initial stage of cortical exhaustion, whether toxic or otherwise. In the other great division, that of delusional insanity arising primarily without immediately recognizable exhausting causes, there must be conceived an inherent asthenia of the nervous system, by which it is rendered less resistive, even to the initial stress of its own normal activities.

There is just one thing more in the philosophy of this matter that ought to be said here. The purely mental causes or beginnings of insanity should always be taken into account. There is only need to remember the intimate connection of mind and body, the physical accompaniments of the emotions, the depressing effects of fear through the sympathetic and vaso-motor mechanisms, upon circulation and nutrition. Mental shock, or prolonged anxiety and worry from real causes, may initiate the exhaustion from which all else may follow, in the regular pathological sequence which I have described, on the lines of overwork of the neuron, exhaustion, auto-intoxication and increasingly aggravated mental symptoms in a descending scale. The process of cure should begin with the arrest of this descent toward dementia, and must go on with a gradual and often slow recovery of functional power in the neuron. If the morbid process has not gone too far, regeneration of the neuron and the cell contents may occur, otherwise there may be some degree of chronic degeneration, and thus begun, the descent continues toward dementia.

Now that mental pathology is becoming clearer in the light of general pathology, shall not a new interest arise in the study and treatment of insanity? Already the practice of alienists is getting upon new lines. Great success has been attained in some torpid mental and bodily states of long standing by the use of thyroid extract. Much attention is being given to the disinfection of the intestinal canal and its systematic and thorough evacuation by high enemata. Elimination of retained auto-intoxicants has been attempted with some success by the subcutaneous injection of large doses of a solution of common salt. These and other procedures are still largely experimental. But whatever you do, while you exhibit all the effective tonics, of which nutrition, rest and sleep, are the best, there is one controlling practical principle to be remembered, and, with this, one special caution. It is a safe rule that mental symptoms always mean weakness; excitement is an extreme degree of irritable weakness, in which there is great exhaustion in the mechanism of mental control. This thought should beget care in the use of sedatives and hypnotics.

Beware of the coal tar compounds and the like; they are good and sometimes necessary for proper use, but not for many days in succession. Change them and omit for a while; they go against nutrition, and drug intoxication often aggravates the disease and is mistaken for it. When your patient is taking food well, be content with his getting two or three hours of sleep or less in each twenty-four hours, even when excited. Such sleep is better than when it is drug produced. When the appetite flags and sleep is not produced by persistence in hypnotics, the complete suspension of all medicines, and frequent feeding will often be followed by gradual cessation of excitement, a clearing tongue, and improvement in sleep. These brief hints are simply mentioned by way of example. Above all things it should be remembered that the indication is always for a "supporting treatment."

OBSERVATIONS UPON PULMONARY TUBERCULOSIS IN COLORADO.¹

BY S. G. BOXSEY, A.M., M.D., DENVER, COL.,
Professor of Medicine, University of Denver; Visiting Physician, St. Luke's Hospital.

THE object of this paper is to institute an inquiry, from a clinical standpoint, as to the relation of the Colorado climate to the course of pulmonary tuberculosis.

For its proper consideration a large experience is essential, to be secured only from a prolonged residence in the State in constant intimate association with the disease, with ample facilities for extended investigation.

Although appreciative of the exhaustive nature of the subject, and mindful as well of my own limitations, I venture to offer the results of my experience, together with brief statistical data, in the hope that therefrom may be derived some approximately accurate and practical conclusions. It is not my intention to enter into an elaborate analysis, as I am somewhat sceptical as to its practical utility.

My opportunities for observation have been extended through a residence of five and a half years in Colorado. I present, however, a series of 200 cases seen in private practice during a period of two years. These cases have been carefully selected, subjected to continued personal supervision, and conscientiously recorded.

In order to obtain great accuracy of conclusions, an effort has been made to include only those in the list whose condition upon arrival seemed to be especially applicable to the climate, and who have subsequently remained under constant observation.

No case is presented that has been observed for less than six months, nearly all, however, having been seen during a much longer period.

The diagnosis was confirmed by examination of the sputum in all cases where the physical signs did not furnish indubitable evidence of the nature of the affection. In fact, this was adopted as a routine measure in the majority of instances.

Considerable difficulty was experienced in the proper classification of the cases. Usually quite extensive infection had taken place before the arrival of the patient

¹ Read at the Fourteenth Annual Meeting of the American Climatological Association, Washington, D. C., May 5, 1897.

in Colorado. The very incipient stages were therefore but exceptionally observed, while far advanced cases with practically hopeless prognosis were not admitted in the list.

It may be fairly assumed, therefore, that the 200 cases form a rather distinctive class, embracing in a general way those with pronounced tubercular infection, which would have pursued an unfavorable course at home, but offered reasonable assurance of improvement in Colorado.

Further classification, made solely with reference to the stage of the disease or the extent of the process, would be, I believe, very misleading. I have preferred to make the division according to the individual prognosis at the time of arrival, the estimate of which was based upon a careful review of all the factors having a possible bearing upon the case, without exclusive reference to the area or degree of pulmonary involvement.

There are three classes, based upon relative prognosis :

CLASS A. Prognosis excellent. Moderate infiltration, limited to one lobe or a portion of the same; evidences of moisture; no softening; pulse, appetite and digestion good; temperament sensible. Other considerations favorable.

CLASS B. Prognosis fairly good. More extensive involvement of one lung, or portions of both, namely: consolidation of one lobe with moist râles, or with possible beginning cavity formation; partial consolidation of entire lung, with evidences of moisture; infection of both lungs, with signs of consolidation limited to apices or thereabouts.

Finally, cases that, from consideration of physical signs alone would belong to "Class A," but owing to nervous, circulatory or digestive disturbances, or other unfavorable circumstances, would properly come under "Class B."

CLASS C. Prognosis doubtful. Extensive active infection limited to one lung, with or without small or moderate-sized cavities. Definite invasion of both lungs, with but moderate activity of the process. Cases with somewhat less pronounced pulmonary involvement, but with considerable constitutional impairment, or associated with other obviously unfavorable factors.

I am too well aware of the deficiencies of this method of classification, but have been able to adopt none other affording upon the whole equal satisfaction.

In describing the results obtained, I make no mention of any cases as cured.

By apparent total arrestment, I allude to entire absence of moisture, or of other evidences of activity of the tubercular process, complete cessation of cough or expectoration, and no apparent constitutional disturbance.

By marked improvement, I refer to an excellent general condition, frequently sufficient to justify the performance of work, but the persistence of signs of slight existing trouble, with or without morning cough or expectoration.

By improvement, I refer to a material lessening of the activity of the process as disclosed by physical signs, diminution of cough and expectoration, lowering of pulse and temperature, increase of appetite, digestion and weight.

Of the 200 cases under consideration, 40 are included in Class A, as follows :

Apparent total arrestment	21
Marked improvement	7
Improvement	8
No change	2
Dead	2

Thirty-six out of 40, or 90 per cent., have received material benefit.

Class B numbers 54 :

Apparent total arrestment	10
Marked improvement	21
Improvement	12
No change	5
Grown worse, or dead	6

Forty-three, or over 79 per cent., have gained in this class.

Under Class C, with a total of 106, the results are :

Apparent total arrestment	2
Marked improvement	29
Improvement	28
No change	15
Distinctly worse, or dead	32

Over 55 per cent. have improved, a large proportion in view of the character of the cases considered in this class.

The results obtained for the entire number, without distinct reference to class, are :

Apparent total arrestment	33
Marked improvement	57
Improvement	48
No change	21
Grown worse, or dead	40

Sixty-nine per cent. of the cases have improved in Colorado; 45 per cent. have made very decided improvement; 16½ per cent. have obtained complete arrestment of the tubercular process.

The significance of these figures is emphasized by the comparatively short period of observation.

It is manifestly fair to assume that a fair proportion of those classed as *much improved* will, in the course of a more prolonged period of observation, obtain ultimate complete arrestment.

In like manner, it may be expected that several exhibiting moderate improvement now may subsequently be placed in the column of *decided improvement*.

There appears, however, from my own experience, but little probability, save in exceptional instances, of any very distinctive change for the better taking place in those who had failed to show improvement during one year in Colorado, if under competent medical supervision.

In justice to the climate, an important modification of these results should be explained by the effects of intercurrent disease, accident and pronounced individual indiscretion.

Among the 62 cases reported as not having responded favorably to the climatic influences, 11 had previously done well, but in whom subsequent failure may be ascribed as follows :

Appendicitis; operation, death	1
Empyema; operation, death or grown worse	2
Suicide	2
General tubercular invasion	1
Palpable imprudence	5

Should these facts be admitted in the analysis of results, it would appear from the entire data introduced that about three-fourths of all the cases properly applicable to the climate may be expected to improve.

It is interesting to note that my report of general

results is much in accord with that of Dr. Fisk in his elaborate analysis in 1889 of 100 recorded cases in Colorado.

My further observations are summarized briefly as follows:

AGE.		Cases.	Improved.
Periods.			
17 to 20	12	8, or 66%
20 to 30	102	75 73
30 to 40	67	41 61
40 to 50	14	10 71
Over 50	5	4 80

From these figures, the influence of age within certain limits upon the course of the disease in Colorado would seem but slight, although somewhat in opposition to the generally accepted opinions. The similarity of results at the several periods of life referred to is somewhat surprising, but is nevertheless offered for what it is worth as perhaps one of the anomalies of my experience.

SEX.		
Males, 145.		
Improved	100, or 69%
Females, 55.		
Improved	38, or 69%
Married Females, 21.		
Improved	12, or 57%
Unmarried Females, 34.		
Improved	26, or 76%

It was noticed that a very large proportion of the males came to Colorado alone. Of the females, those who were married were almost invariably accompanied by husband or children. The unmarried females were found, with two or three exceptions, to be under thirty years of age. The practical points to be recognized from reference to the above are —

(1) Notwithstanding the fact that the disease has been universally found to attain greater prevalence among the members of the female sex, yet opportunity for a possible arrestment by a change of climate is not offered to the female nearly as frequently as to the male.

(2) That the percentage of improvement in females is materially greater in those who are unmarried and without family enmeshments.

(3) That, despite obvious adverse conditions and contrary to established conclusions, the female in this series of cases has responded to the favorable influences of the climate equally with the male.

Lest this be regarded purely as an instance of the strange fallacies of statistics, I offer several possible explanations in support of my results.

In Colorado, the question of success or failure in the effort to secure arrestment depends largely upon the ability of the individual to conform to a proper regimen of daily life, entailing for its greater perfection certain physical and mental requirements. These, I believe, are possessed to a greater extent by the female.

I cannot see that the separation from family is essentially harder for her to bear than for the male. On the contrary, she seems to adapt herself to strange conditions quite as quickly and as comfortably. While, in general, less opportunity is offered for an existence in the open air with judicious exercise, a life of more complete rest is assured, with perhaps as many hours of sunshine. There is less chafing under restraint, less of the cares and responsibilities of life, less tendency to acts of imprudence, and, from my experience, more implicit obedience to detailed instructions.

It is but fair to add that the financial circumstances of the female invalid in Colorado are in general relatively superior to those of the male. It is no uncommon occurrence to meet the young man with extensive tubercular infection and insufficient means, who has been sent to Colorado (and usually to Denver) with instructions to secure immediate employment by which to supply his necessities. In the event of either success or failure in his effort to find work, the battle is for him against great odds. As a general rule, cases with such limited resources are better at home.

The female invalid does not usually seek change of climate unless proper provision has been made for her support.

RACE. DISTRIBUTION. PREVIOUS ENVIRONMENT.

Fifty-three, or rather more than one-fourth of the cases occurred in those of direct foreign descent, although many were born in this country, and in most instances from the better class. It does not seem profitable to enumerate statistics relative to the several nationalities.

The 50 cases are distributed somewhat equally among the Jews, Irish, Germans, Scotch, Swedes, English and Canadians.

The Jews, numbering eight, have almost uniformly shown more extensive pulmonary involvement upon arrival, but have exhibited apparently greater resisting power than any other race. I have been impressed with the disproportion in these people between the physical signs and the general condition. While the course of the disease has been usually prolonged, the process of arrestment, on the other hand, has been slow and disappointing. The Jew has been invariably obedient and conscientious to the last degree in following instructions.

The Irish, from my experience, have seemed to be more especially predisposed than others. The disease has been more rapid, the process more active, with greater tendency to nervous disturbances, and the patient harder to control.

The Swedes, although apparently hardy and vigorous, have succumbed much more quickly than those of our own country. They are usually exceedingly apprehensive, and easily managed.

It has been my general experience that the Germans, Scotch, English and Canadian adapt themselves quite readily to an appropriate system of living, excelling in this respect our more restless Americans.

The latter number 147 in my series of cases, and are principally from New England and the extreme Eastern States. The list includes 30 from the Middle States, 10 from the South, and strangely, none from the region west of the Rocky Mountains.

I think it may be said that certain tendencies incident to previous surroundings and environment are, like racial characteristics, not without some influence in modifying the course of the disease. The lighter the burden of business responsibilities, the more phlegmatic or philosophical the individual, with less of general restlessness or irritability of temperament, the better the prognosis.

Too frequently the patient comes to Colorado for a prescribed number of months. His recovery must take place in that period, as no further extension of time can be diverted from his business, which he often continues to conduct by correspondence, and mean-

while indulges occasionally in speculative investments in Colorado.

The previous occupation appears also to possess some significance. From my experience, those who have previously led sedentary lives are likely to do better upon coming to Colorado, under a system of rational management, than those who have been accustomed to outdoor occupations, the obvious explanation being the opportunity permitted for greater change in the mode of life, and consequent greater impression upon the course of the disease.

INHERITED PREDISPOSITION.

Seventy-seven of my cases present a history of previous family taint. Without entering upon an unnecessary analysis, it is of some interest to state that in nearly one-half the cases, brothers and sisters were alone affected.

In noting final results, there are singularly no distinctive differences relative to the source of the inheritance. The percentage of improvement for the entire number is 60, as compared with 72 per cent. for those with no apparent inherited susceptibility. May not the similarity of results possess some significance in the proper estimate of the influence of predisposing causes other than those of inheritance?

The frequent existence of definite predisposing causes among several members of the same generation in one family, without history of immediate inheritance, is to my mind strong supplementary evidence in support of the view that the relation of heredity to the etiology of the disease consists, as a rule, not in the direct transmission of the bacillus, but in the increased vulnerability of pulmonary tissue, with diminished resisting power of the individual.

The occasional occurrence of congenital tuberculosis is demonstrated by the detection of the bacilli in the placenta or in the organs of the newly born, as well as by the positive results in exceptional instances, attending inoculation in guinea-pigs from the placenta, or the organs of the child, despite the failure to discover either the bacilli or the evidences of tuberculosis in the tissues.

Inasmuch, however, as negative results have frequently followed similar investigations, even where active tuberculosis existed in the mother, it is safe to say that no conclusive testimony has yet been adduced to substantiate any frequency of intra-uterine infection.

EXTENT AND CHARACTER OF PULMONARY INFECTION.

At the time the cases came under my observation, the tubercular process was limited to the right lung in 59 cases, to the left in 31, and with involvement of both in 110.

The fact that more than one-half of those in my entire list came to Colorado with pronounced signs in each lung should emphasize, I think, the necessity for earlier diagnosis and more prompt climatic treatment.

It is somewhat remarkable that the percentage of improvement for those with double infection is nearly equal to that of those with single lung invasion.

Well-defined cavities have been recognized in 23 cases, in 13 of whom the improvement has been very perceptible.

The significance of these facts must be to the effect that the prognosis is dependent not alone upon the

area of involvement, nor the degree of tissue destruction, but as well upon the present activity of the process, and upon the influence of other factors of recognized importance.

I desire to make mention of the frequency with which I have found localized areas of active infection in the mid-scapular space, with no signs elsewhere in the same lung.

I feel that this region, the importance of which is perhaps hardly appreciated, is occasionally the seat of the only active trouble existing within the chest, the same not infrequently escaping recognition. I am also led to believe that signs of incipient infection in the axilla of the apparently non-affected side are occasionally overlooked.

In the extension of the tubercular process from the right lung to the left, I have several times observed the locality first infected to be the tongue-like projection of lung covering the apex of the heart, the signs extending slightly to the left before evidence could be detected of involvement elsewhere.

MODE OF ONSET.

Thirty-eight cases were said to have been shortly preceded by *la grippe*. The history usually given was that of an acute attack of but few days' duration, attended with cough, which persisted or subsequently returned. In round numbers, 60 per cent. of these have improved in Colorado.

Thirty-two cases were associated with hemorrhage in the very early stages, this being the first intimation of existing trouble. Over 84 per cent. have made improvement.

Seventy-six cases conform to the anemic type; percentage of improvement, 59. Seventeen began with symptoms of *cold*, 82 per cent. showing an improvement.

The remaining cases either followed pleurisy, with or without effusion, pneumonia, typhoid fever, measles, or whooping cough, statistical observations concerning which are hardly profitable.

Special attention is called to the prevalence of *la grippe* as a causal factor, with its relatively unfavorable results, the high mortality-rate attached to cases of insidious anemic origin, and the remarkable percentage of improvement obtained in initial hemorrhagic cases. The probable explanation of the latter is found in the opportunity offered for more early diagnosis, and more prompt removal to Colorado.

RELATION OF CLIMATE TO CASES WITH HEMORRHAGE.

Seventy-eight of my cases presented the history of one or more hemorrhages before arrival. Of these 13, or about 16 per cent., had recurrences subsequently. Seven were distinctly of aneurismal origin, occurring after long periods of relief, and induced by obvious acts of over-exertion, or other indiscretions.

Of the remaining 122, eight have experienced their first hemorrhage since coming to Colorado.

With reference to the general condition, the percentage of improvement for the entire number of hemorrhagic cases is 79; for the non-hemorrhagic cases, 62 per cent.; for those with previous hemorrhage, but no recurrences in Colorado, 87 per cent.; for those with subsequent recurrences, 38 per cent.; for those with initial hemorrhage occurring after arrival, 37 per cent.

A comparison of these results would indicate broadly that hemorrhagic cases do remarkably well in Colorado, even better than the non-hemorrhagic; that the proportion of recurrences is small, that cases with recurrent hemorrhages after arrival are less favorable, and that hemorrhages *beginning* in Colorado are attended with still more serious results.

In general, I am impressed with the restraining influence of the climate upon the tendency to repeated hemorrhages in those cases of more remote origin, but question the effect of the altitude upon those of very recent date, the very means of subsequent protection becoming at first a source of increasing danger.

Hemorrhages beginning in Colorado are apt to be severe, being in very many instances of the aneurismal type.

I am not prepared to venture any clinical opinion as to the general severity or degree of shock attending hemorrhages occurring in Colorado, as compared with the same at lower elevation, on account of insufficient opportunities for observation at the sea-level. My patients, however, from their own experience, have seldom been able to perceive any marked differences in this respect.

Since the compilation of these results some two or three months ago, I have been forced to recognize the existence of a considerable number of exceedingly small hemorrhages without disastrous results among patients apparently doing well, the most of whom, however, are not included in this list.

In view of the uniformly benign character, their origin is presumably incident to slight disturbances of circulation consequent to retrogressive interstitial contraction, and hence a possible indication of the favorable progress of the disease.

FUNCTIONAL NERVOUS DISTURBANCES.

It is frequently urged that residence in high altitudes for the consumptive is contraindicated by the coexistence of certain nervous phenomena, as severe and protracted headaches, insomnia, irritability and other manifestations of hysteria. The reason adduced is the supposed aggravation of the nervous symptoms, and the consequent unfavorable influence upon the course of the tubercular disease.

The inference implied is that improvement in the nervous derangement must precede any change for the better in the lungs.

These conclusions, however, are not borne out by the established facts of experience.

The observations for many years in Denver of the neurologists, Drs. Eskridge and Pershing, indicate no influence of altitude whatever upon functional nervous disorders. With this, my own experience relating to the nervous disturbances to the pulmonary invalid is in complete accord.

Fourteen of my patients included in this paper exhibited nervous symptoms to such an extent as to seriously prejudice the chances of recovery. No history could be obtained of any aggravation of the same upon coming to Colorado.

Nine have obtained partial arrestment of the process and material improvement in the general nervous condition. Two have shown no abatement of physical signs, but have made a distinct gain from the standpoint of the neurologist.

I am convinced that such results could not have been secured in the warm, moist climate with low

elevation, so frequently recommended for this class of patients.

I recognize that the existence of pronounced nervous manifestations offers a serious obstacle to improvement in any climate, but regard the pulmonary infection as the paramount issue, and insist upon the functional derangement as demanding greater attention to details of management, rather than change of climate.

I have frequently observed improvement in neurotic, as well as other cases, following change of surroundings, without the slightest difference in climatic conditions, as even from one section of Denver to another.

The psychical influence of the change appears to be the essence of the benefit produced. It has invariably been the case that improvement in the nervous symptoms has been in proportion to the degree of arrestment and the gain in the general strength.

BRONCHIAL IRRITATION.

It must be admitted that this annoying condition exhibits a tendency to persist for a period, or to become temporarily aggravated in Colorado. I am convinced, however, that in but exceptional cases does there exist any relation to the prognosis. The possible irritative effect of the altitude and dryness upon the bronchial mucous membrane, disagreeable though it may be, is by no means a criterion of the precise influence of the climate. The efficiency of the latter is measured solely with reference to the subsequent course of the tubercular process, which is the only consideration of especial importance.

The bronchial irritation presented in these cases is of minor significance, and may be assumed to be rather an expression of individual idiosyncracies, susceptible in nearly all instances of decided amelioration under a proper régime.

Twenty-three of my cases suffered to a greater or less extent from a frequent dry, useless cough, often of a paroxysmal nature, and subject to exacerbations, without apparent cause. In all these, the irritative bronchial character was sufficiently defined to permit distinct classification.

Thirteen have made decided progress toward arrestment of pulmonary disease, with a correspondingly marked diminution of the bronchial irritation.

Five are about the same with respect to the active process, but with bronchial irritation much diminished.

One is doing poorly, with bronchial irritation less.

One is doing poorly, bronchial irritation not diminished.

One is about the same, but with bronchial irritation unchanged.

Two are dead.

The results obtained are certainly satisfactory, and if possessed of any value from which to draw provisional conclusions, would suggest that the presence even of a considerable degree of bronchial irritation is to the pulmonary invalid no contraindication for the Colorado climate.

Only in cases where this condition is associated with or dependent upon extensive pathological changes, involving the pulmonary or circulatory apparatus, of themselves demanding a different climate, would I consider such a course advisable.

I will add in this connection that I have not regarded the existence of simple valvular heart lesions as necessarily contradictory to high altitudes for the con-

sumptive. Aside from gross degenerative changes or dilatation, I believe that the question of residence for the consumptive, with cardiac complication, must be settled solely with reference to the relation estimated to exist between the demands for work upon the heart, and its power to respond to the same.

FEVER.

There is perhaps no single feature in the final estimate of the prognosis of greater importance than the temperature, as denoting the degree of activity of the process, and the measure of individual resistance.

Cases presenting the fever of septic absorption are not included in this list, the most of my cases conforming to the intermittent type of tuberculization or ulceration.

Sixty-eight upon arrival exhibited daily in the afternoon a temperature of 100.5° or over; 55 per cent. of these have gained very perceptibly.

From my general observation I do not incline to the opinion that fever is increased in Colorado, or that pyrexia in itself (other conditions permitting) is a contraindication for high altitudes.

COMPLICATIONS.

Among the various complications, simple mention is made, without reference to statistics, of the occasional development of empyema, pneumothorax, fistula, syphilis, sarcoma, purpura hemorrhagica, acute rheumatism, typhoid fever, and tubercular involvement of brain, glands, intestines, bones and epididymis.

In six cases, the tubercular process developed in patients who had been subject for some years to genuine asthma. These have all done well in Colorado. I do not refer, of course, to the dyspnea of symptomatic asthma, dependent upon pronounced pathological changes.

There is one complication, however, of especial interest, and worthy of more extended notice — tubercular laryngitis.

Twenty-one of my patients have suffered from this condition. Six have shown general and local improvement. Ten have grown worse. Five have died.

In ten the disease existed before arrival. Four of these have done well. Six have died or grown worse.

In eleven the laryngeal involvement developed in Colorado. Of this number, however, seven presented no evidence of the disease until a few weeks before death from pulmonary involvement, and therefore without especial significance.

Of the remaining four, who may be fairly said to have developed the disease in Colorado, two have improved in every way.

These results do not suggest any deleterious effects of the climate with reference to the development or the course of laryngeal tuberculosis. In fact, with local treatment, improvement in this respect is largely commensurate with the gain in the general condition.

The existence of tubercular laryngeal involvement, and especially if not confined to the interior of the larynx, is a serious complication in any climate.

MANAGEMENT.

Without enumeration of details, I may state that none but the more rational and conservative measures of treatment have been employed. In no instance has use been made of tuberculin, anti-phthisin or nuclein injections, inhalations of any kind, the various forms

of breathing appliances, or other special methods of treatment with their modifications.

The general essentials recognized have been an inactive life in the open air during as many hours as possible in the day-time; the maximum amount of proper nourishment, contentment of mind, attention to digestive and other disturbances, as they arise; strict regard to the minor details of daily life, with occasional admonitions, frequent reassurances, but constant vigilance.

The patients have been uniformly instructed, as far as practicable, concerning the true significance of their condition, in the hope of appealing directly to their own intelligence, and securing their more active co-operation.

An effort has been made to recommend, from personal knowledge, suitable accommodations providing proper conditions for the individual case.

I have preferred a residence in the higher and more thickly settled portions of the city or neighboring ranches, and during the summer-time, removal to the mountains. The latter is usually of decided benefit.

A large proportion of the reported cases spent the summer of 1896 at the same mountain resort, thus admitting closer medical supervision than if widely scattered, and with altogether more satisfactory results.

Strychnine has been of chief importance in my medicinal therapeutics, together with nutrients, creosote to a moderate extent, and rational measures looking to the relief of cough, as well as digestive, circulatory and nervous disturbances.

No matter how complete the arrestment, I have never approved of a permanent return to the previous conditions of climate or general surroundings.

The increased expansion with vesicle dilatation resulting from a somewhat extended residence in elevated regions, is no argument against the selection of Colorado as a health resort, but does constitute one of the strongest objections against a subsequent return.

I will submit for your acceptance my conclusions, namely:

That climate offers to the pulmonary invalid greater assurance of improvement than can be otherwise obtained.

That the meteorological conditions along the Eastern Rocky Mountain slope are especially applicable for this purpose.

That throughout this region, portions of Colorado surpass other localities by virtue of her immensely superior accommodations, her increased social advantages, and, later on, her favorable business opportunities.

That a greater number may be expected to acquire ultimate permanent arrestment, or at least secure material improvement in this State than elsewhere.

That residence in Colorado, at an elevation of from 5,000 to 7,000 feet, is indicated for the large majority of cases without especial reference to age, sex, race or family predisposition.

That functional nervous derangements, bronchial irritation, pyrexia, moderate-sized cavities, tubercular laryngitis, and valvular cardiac lesions are not of themselves contraindications to the high altitude.

The hemorrhagic cases, within limits previously mentioned, are peculiarly appropriate for the Colorado climate.

Broadly speaking, that the only cases unsuited for residence in this State are those with very extensive

infection, considerable destruction of pulmonary tissue, enfeebled cardiac power, well-marked sepsis or exhausted finances.

That the benefit derived is dependent, not upon climate alone, but as well upon the conscientious attention to mode of life and management.

That for the successful management, conservative rational measures are essential to the exclusion of the special methods.

Finally, that cases should come early and come to stay.

REPORT OF FORTY CASES OF INTUBATION.

BY CHAS. B. STEVENS, M.D., WORCESTER, MASS.,
Visiting Physician to the Worcester Isolation Hospital.

STENOSIS of the larynx may be due to pseudo-membrane or to inflammatory edema; and these may be caused by Klebs-Löffler bacilli, streptococci or staphylococci. The stenosis may be associated with measles or scarlet fever. The cases here reported illustrate these various causes. The list includes 22 intubations done in private practice and treated by antitoxin, with eight deaths; six intubations done at the Isolation Hospital, with no deaths. Mortality, 29.5 per cent. Aside from these were two cases in private practice, not treated by antitoxin, both fatal in a few hours. There were also 10 cases not diphtheria, with three deaths. Total 40 intubations, with 13 deaths, mortality 32.5 per cent. These represent cases in which either tracheotomy or intubation seemed imperative to relieve fatal dyspnea.

The diagnosis of obstruction by inflammatory edema was made in three cases of dyspnea after measles. Laryngitis complicating measles is associated with bronchitis and broncho-pneumonia. Probably serious stenosis of the larynx could occur only in small children. Two of my patients were under two years, the other was six and one-half years old.

The indication for operation was the character of the breathing, which was similar to that of laryngeal diphtheria. There was retraction of the soft parts of the neck, and especially of the epigastrium and ribs along the attachment of the diaphragm, in distinction from the dyspnea of broncho-pneumonia in which the intercostal spaces are drawn in but the epigastrium not markedly. Respiration is slower in laryngeal obstruction and faster in broncho-pneumonia. Whatever was the cause of the dyspnea, it was clear that the dyspnea was extreme and that the operation gave immediately relief, proving that the stenosis had been mainly in the larynx. In all three cases there was long-continued coughing after intubation, which is evidence of bronchitis. In all there was difficulty in getting along without the tubes during convalescence, so that each had to be replaced once or twice. Antitoxin was not injected in any of these cases because diphtheria was not supposed to be present and cultures revealed no Klebs-Löffler bacilli. The cultures were taken from the throats and from the tubes after removal. All three cases recovered.

CASE I. F. G., age one year, ten months. Wore tube twelve days. Two older sisters (ages three and five) had been having measles, and had had difficult breathing. The patient had been ailing one week,

and had had trouble in breathing, when in the afternoon of November 9th he became suddenly worse.

November 9th, 8 p. m. I found a distinct measles rash; pharynx red; breathing irregular and very labored, with extreme retraction of the epigastrium and soft parts; cyanosis and exhaustion. Pulse 180, temperature 101.4°, respiration 50. Intubation done; relief immediate. Cyanosis disappeared, the pulse dropped to 120, and the patient fell asleep and slept most of the night. He was allowed to drink milk from a glass during the night.

November 10th. I attempted to feed by the nasal tube; but the nares were too small, so I allowed the child to drink milk from a glass, as it produced little coughing. Semi-solids were also given. Patient comfortable, sitting up in bed; pulse 120.

November 11th. Thirty-six hours after intubation the tube was extracted. Dyspnea returned at once and increased so that in twenty minutes the tube had to be replaced. Relief was immediate; the pulse dropped from 180 to 120, and the patient fell asleep. For four days more the child was very comfortable. Temperature 99° to 100°, pulse 120, respiration 30. Some coughing.

November 15th. Tube again removed, but after two hours was replaced for extreme dyspnea and exhaustion.

I waited six days more. The patient's condition continued good. Temperature 99° to 100°, respiration 30 to 35.

November 21st. Tube removed for the third time. At first there was no obstruction, but it soon returned, and the child was put in the bathroom, which was filled with steam and sublimed calomel. This relieved the dyspnea; and from this time convalescence was uninterrupted. Cultures from the throat showed no Klebs-Löffler bacilli. There was no evidence of diphtheria and no history of contagion. It was simply a case of measles.

CASE II was very similar. G. A., age one year, eight months. Tube worn twenty-three and one-half days.

¹ Read before the Worcester Medical Association, April 14, 1897.

January 31st. Began to have measles.

February 4th. Intubated by Dr. R. P. Watkins, assisted by Dr. J. M. W. Farnham. Measles rash present. No membrane in throat.

February 8th. Tube extracted; replaced in fifteen minutes.

February 16th. Tube again extracted; replaced in half an hour.

no false membrane seen, and no history of contagion, but only an inflammation of the air-passages associated with measles. The difficulty in getting rid of the tubes was probably due to return of edema as soon as the tubes were taken out.

CASE IV. Following these cases of measles above, comes one of measles and diphtheria combined. J. M., two years old. Tube worn two hours.

DIPHTHERIA.			Age.	Day of Intubation.	Tube worn.	Day of 1st injection of Antitoxin.	Number of injections.	Total amount of Antitoxin in units.	Membrane in Throat.	Termination.	REMARKS. (All had Klebs-Löffler bacilli in culture.)

February 27th. Tube again extracted, and re-
maind out. Convalescence uninterrupted.

CASE III. I. B., age six and one-half years.

November 25th. Began to have "measles and
croup."

Croup continued every night for three weeks.

December 17th. Symptoms much worse. Patient
in *extremis*. Intubated. Immediate relief.

December 20th. Tube extracted; replaced in two
hours.

December 28th. Tube again removed. Convales-
cence uninterrupted.

In these cases there were no Klebs-Löffler bacilli,

January 31st. Began to have measles.

February 3d. Seen by a physician, who made a
diagnosis of broncho-pneumonia, and said that the
child would die during the night.

February 4th. At 10 A. M. was seen by another
physician, who advised intubation. At 5 P. M. I found
the patient moribund and unconscious. There was
extreme retraction and cyanosis, and the pulse could
not be counted. Measles rash present; no membrane
seen in throat; and I thought the case was one of
broncho-pneumonia with edema of the larynx due to
measles, without diphtheria, and did not expect much
benefit from the tube and did not inject antitoxin. A

tube was inserted; the breathing was relieved, but remained rapid, and the pulse continued weak and very rapid. One hour later the breathing got worse again, and in two hours the child died. The tube removed after death was not blocked. Cultures taken from the tube after death, and from the throat before intubation, both had Klebs-Löffler bacilli. There was no history of contagion before or afterward. The cause of death was broncho-pneumonia.

The result of intubation in cases of bronchitis or broncho-pneumonia with laryngeal obstruction is further illustrated by the following case, in which cultures showed no Klebs-Löffler bacilli, but a pure growth of the staphylococcus aureus.

CASE V. C. M., twenty-one months old. Tube worn eleven days. Recovery.

January 6th. Began to have a purulent discharge from the ear, and later developed a severe cough.

January 15th. On account of labored breathing two physicians were consulted, who made a diagnosis of bronchitis.

January 17th. The dyspnea had grown worse and more laryngeal, so that intubation was advised. At 7.30 p. m. I first saw the patient. I found extreme retraction, considerable cyanosis, extreme exhaustion and severe coughing. A one-year tube was inserted in the larynx, but gave no relief, and death on the table seemed imminent. A two year tube was then put in and the stenosis was immediately relieved; but there was incessant coughing for one hour, and a profuse discharge of mucus, which the child seemed unable to get rid of. No membrane was seen in the throat, but it was thought best to inject 1,000 units of antitoxin. The patient slept most of the night. Coughing was severe at times, and was relieved only by holding the patient's head down so that the mucus that collected might be coughed out. For two days the temperature varied from 102° to 103°, pulse 140 to 150, respiration 25 to 35.

January 19th. The dyspnea increased; the patient got very restless and the respiration more rapid. The condition was alarming. The tube was therefore removed, and found partially occluded. The breathing was better for a few minutes; but it soon grew worse than ever and in half an hour the tube was replaced. This again relieved the breathing, and allowed the discharge of much mucus. A culture from the tube showed a pure growth of the staphylococcus aureus.

For the next three days the child's condition slowly improved. Temperature 100° to 101.5°, but coughing persisted.

January 22d. Tube again removed. It remained out eight hours, but finally had to be put back for cyanosis, exhaustion, dyspnea and weak pulse. The tube again relieved the patient. A second culture showed a pure growth of the staphylococcus aureus.

January 28th. Tube again removed. Hoarseness and a croupy cough continued, but no dyspnea, and recovery was uninterrupted.

In this case there was probably no false membrane, but only inflammatory edema associated with bronchitis. Drugs had been used without success, and the character of the breathing justified intubation and the injection of antitoxin without waiting for the culture.

Laryngeal obstruction may be produced by streptococci, and I have had five cases in which streptococci seemed to be the cause of the trouble. Klebs-Löffler bacilli were absent, but antitoxin was used in all cases

because the symptoms were those of diphtheria. How many had pseudo-membrane in the larynx, I do not know. Some probably did not, their stenosis being caused by inflammatory edema. One had the characteristic false membrane of diphtheria on the fauces, two were simple laryngeal cases, and two had broncho-pneumonia with laryngeal stenosis, and died of broncho-pneumonia.

CASE VI. A. B., one year, five months old. Tube worn thirteen hours. Breathing temporarily relieved. Death from broncho-pneumonia.

CASE VII. M. S., five and one-half years old. Tube worn seventeen hours. Breathing temporarily relieved. Death from broncho-pneumonia. The symptoms at time of operation and history of these two cases were similar to those of Case V.

CASE VIII. J. G., one year, four months old. Tube worn two and a half days. Recovery.

CASE IX. C. C., three years, ten months old. Tube worn four days. Recovery. These two cases had the symptoms of laryngeal diphtheria.

CASE X. G. P., three years, nine months old. Had always been subject to croup. A brother died five years ago of membranous croup after tracheotomy.

January 2d, patient began to have croupy cough.

January 3d. Tonsils and pharynx were covered by a thick white sloughing membrane. Breathing easy. Antitoxin (State Board) 1,000 units injected.

January 4th. Began to have dyspnea and retraction in morning. At 5.30 p. m. retraction and cyanosis were extreme. Patient very restless. Lime and steam had been used with temporary benefit. Intubation was imperative and was done, giving perfect relief. Tube was worn two and a half days. Patient slept and ate well. Temperature 99.5° to 100°, pulse 120 to 140.

January 7th. Membrane had disappeared from the throat so the tube was extracted. No return of dyspnea. Recovery was rapid. Two cultures in this case showed streptococci, no Klebs-Löffler bacilli. The pseudo-membrane in the mouth associated with croup made a typical picture of diphtheria and reveals the similarity of streptococcus infection in its results to true diphtheria. These five cases were not associated with any cases of diphtheria.

Another case in which streptococci were present without Klebs-Löffler bacilli proved to be scarlet fever. The pseudo-membrane on the fauces is quite common in scarlet fever but this membrane rarely extends to the larynx to produce croup. Edema of the glottis is also rare in scarlet fever but may produce death by suffocation. The association of scarlet fever and diphtheria is more common and the larynx may thus be involved; but the following case showed no Klebs-Löffler bacilli in culture and so must be classed as one of the rare cases of involvement of the larynx in uncomplicated scarlet fever.

CASE XI. S. L., three years, eight months old. Tube worn two days. Death seven days later of pneumonia.

December 31st. 1.30 A. M., began to have croup, treated by emetics. Dyspnea continued during the day. At 8 p. m. I found the patient restless and exhausted, considerable retraction. Temperature 102°, pulse 150, respiration 26. Membrane on tonsils. Intubation was done, with immediate relief to breathing, and antitoxin was injected.

The next day temperature, pulse and respiration gradually rose.

January 1st, 5 P. M. Temperature 104°, pulse 168, respiration 33, and a scarlatinal rash was apparent.

January 2d. The tube was removed with no return of the laryngeal obstruction but the respiration remained rapid. Temperature 103° to 105°, pulse 160 to 180, respiration 30 to 50.

January 3d. Pneumonia developed. The temperature ranged from 103.5° to 105°, pulse 150 to 170, respiration 40 to 50 for one week longer.

July 9th. The patient died. Temperature half an hour before death was 109.5°.

The commonest cause of stenosis of the larynx requiring intubation is, of course, diphtheria. I have had 30 such cases with 10 deaths. Six died within twenty-four hours and one died twenty-nine days after removal of tube. The fatal cases will be considered first.

CASES I, II and III. Previously reported.²

CASE IV. Diphtheria and measles, described above. No antitoxin.

CASE V. L. S., two and a half years old. Death from sepsis twenty-nine hours after intubation. Sick one week before antitoxin was injected. Waiting two days for report of culture before using antitoxin, was disastrous in this case.

CASE VI. P. R., ten months old. Death from sepsis eighteen hours after intubation. Sick five days before injection.

CASE VII. H. L., three and a half years old. Had the most extreme dyspnea of all the cases.

November 15th. Began to have cough, aphonia and noisy breathing. Restless and wakeful at night.

November 19th. At 7 A. M. extreme dyspnea came on. At 12.30 P. M. I found the patient deeply cyanosed and unconscious; almost no air entered the larynx. The breathing was characteristic of the last stage of asphyxia, two or three weak respiratory efforts followed by a powerful one. Pulse could not be felt. Hypodermics were given. The mouth was pried open and a tube put in. After a few seconds breathing began again, without obstruction, and color returned. Breathing became regular and deep, but the child remained unconscious and exhausted. At 5 P. M. the symptoms had improved; temperature 103.2°, pulse 168, respiration 33.

November 21st. Temperature 104.5°, pulse 168, respiration 63.

November 22d. Temperature 101.5°, pulse 140, respiration 40. Membrane had disappeared from the throat, and tube was removed. For a few hours the breathing was worse, but the tube did not have to be replaced. After this the child gained strength slowly, and was able to sit up in bed. He was fed at irregular intervals by the mother by Casselberry's method; but the amount was less than a pint of milk per day. The temperature was from 101.5° to 102.5°, pulse 140 to 160, respiration 30 to 40, with much coughing and evidence of bronchitis.

December 3d. The child was sent to the Memorial Hospital because neglected at home. At the hospital fever and cough continued, râles and area of dulness, and finally purulent expectoration.

December 22d. The patient died, twenty-nine days after removal of tube. Autopsy showed gangrene of right lung. The larynx showed a granular condition, most marked about the vocal chords. There was a cicatrix on the anterior wall of the trachea,

opposite the lower end of the tube. Cause of death, gangrene of lung. Gangrene of the lung after intubation is due to inhalation of food, and is generally avoided by care in feeding.

CASE VIII. B. D., five years old. Death in ten hours, from partial blocking of tube.

CASE IX. A. H., four years, eight months old. Death in seventeen hours, from paralysis of heart. The antitoxin used in this case was from a bottle that had been opened several days before.

CASE X. A. B., one year, eight months old. Death in seven hours, from edema of lungs.

December 24th. Had an attack of croup at 6 A. M.

December 25th. At 9 A. M. dyspnea came on again. Seen by physician at noon. No membrane in throat. Diagnosis made of croup. Inhalations of lime and steam, and emetics, were later used. The symptoms grew worse. At 11 P. M. child cyanotic and pulseless. Strychnia and brandy brought up the pulse. Apomorphine (one-twentieth of a grain) was given for further emesis. At 1 A. M. I found the child *in extremis*, pulseless, respiration very rapid, retraction extreme. Tube inserted, which relieved obstruction, but respiration continued rapid and superficial. Respiration 70, temperature 105°, pulse 200. Brandy and strychnia revived the patient, and she coughed up a quantity of mucus, which collected faster than she could get rid of it. She soon grew worse, and died seven hours after intubation. Culture from tube after death showed Klebs-Löffler bacilli. No antitoxin was used. This patient should undoubtedly have been operated on earlier, and was made worse by emetics and lime inhalations, which were used too persistently in this case by the parents.

The recoveries are more encouraging. All were treated with antitoxin.

CASES I to V. Previously reported.³

CASE VI. C. T., eleven years old. Wore tube four days.

June 25th. Taken with sore throat; membrane on tonsils. Temperature 103°.

June 27th. Began to breath noisily.

June 28th. Began to have dyspnea.

June 29th. Breathing became worse in early morning. At 9.30 I found breathing noisy; slight retraction when quiet; very little action of the sterno-mastoids; no cyanosis; little fatigue. Pulse 140, temperature 101°. Extensive membrane in throat. I injected antitoxin (2,500 units, Gibier), and decided to wait. After three hours retraction of the epigastrium became marked, and after six hours cyanosis and exhaustion followed. Pulse 162, temperature 102.5°. At 4.30 P. M. intubation done, with perfect relief. From that time the patient breathed quietly and slept well. Was fed every four hours by the nasal tube. At 10.30 P. M. injected 1,300 units of antitoxin.

June 30th. At 9 A. M. injected 1,200 units. The membrane, which at first covered tonsils and pharynx completely, began to disappear in two days and in four days only a bit remained on the uvula.

July 3d. Tube removed. Dyspnea did not return. Convalescence uninterrupted.

CASE VII. J. S., two years, one month old. Tube worn three days. Tube coughed up once; replaced in half an hour for dyspnea. Rapid convalescence.

CASE VIII. M. S., three years old. Tube worn three days.

² Boston Medical and Surgical Journal, July 9, 1895.

³ Boston Medical and Surgical Journal, July 9, 1896.

CASE IX. M. D., five years old. Tube worn four days. Sepsis and nephritis.

September 28th. Began to have croup. For five days was dressed in daytime, but croupy at night.

October 3d. Vomited after breakfast, after which breathing became suddenly bad. At 2.30 p. m. I found the respiration rapid and labored, retraction marked, color cyanotic. Child exhausted and unconscious, in the last stage of asphyxia. Pulse 100. Intubated; relief immediate, but not perfect. Respiration and color gradually improved. Antitoxin, 800 units. At 3 p. m. temperature 102.6°, pulse 164, respiration 30. The urine contained albumin, one-eighth per cent. Feeding was at first by the nasal tube, but there was difficulty in passing it, so the child was allowed to drink. This careless feeding was probably responsible for continued cough during convalescence.

October 4th. Temperature 104.5°, pulse 165, respiration 40, albumin, one-half per cent.

October 6th. Symptoms improved.

October 7th. Albumin, one-half per cent. At 2 p. m. I found the temperature 104.2°, pulse 156, respiration 44; color worse, respiration labored. At 4 p. m. extreme dyspnea and cyanosis came on from blocking of the tube. Tube extracted; relief immediate.

Convalescence was slow but uninterrupted. Albumin, one-half per cent., continued for one week. The recovery of this case was not expected, and the condition was worse than that of other cases that proved fatal.

CASE X. E. A., five years, ten months old. Tube worn three days. Nephritis.

CASE XI. M. L., seven years old. Tube worn four days.

CASE XII. E. P., seven years old. Tube worn three days. Had a previous attack of diphtheria three years ago.

CASE XIII. D. L., six years, ten months old. Tube worn three days. Had been sick five days with diphtheria, as shown by membrane in throat and Klebs-Löffler bacilli in culture, but the symptoms were not considered severe enough for using antitoxin. However, dyspnea came on suddenly in the night, and at 10 A. M., January 12th, I found the patient much exhausted. The pulse was weak, marked retraction, some cyanosis. Intubated, with immediate relief. Mulford's antitoxin (1,000 units) injected. The patient got along well while the tube was worn; was fed at first by inversion, but when she resisted she was fed by the nasal tube.

January 15th. Membrane had disappeared, and tube was removed. No return of dyspnea. Convalescence uninterrupted.

CASE XIV. R. H., five years old. Had been ill three or four days.

March 18th. At 4.30 p. m. I found membrane on tonsils, aphonia, and croupy cough. Dyspnea came on temporarily after attempts to look in throat. Temperature 100.6°, pulse 144, respiration 20. The girl was able to sleep, so intubation was not indicated. Antitoxin (2,000 units) injected. After this the breathing grew worse, extreme retraction and cyanosis came on, and inability to sleep. Patient exhausted; pulse 160, weak. At 10 p. m., longer delay being impossible, a tube was inserted in the larynx. No relief, no air entered the lungs. Tube quickly extracted, and breathing began again. Loose membrane had been

pushed down before the tube and blocked it. Breathing was good for a few minutes, but soon grew worse, so that the tube was again put in the larynx, this time with perfect relief.

March 22d. Tube removed. Convalescence uninterrupted.

CASES XV-XX were treated at the Worcester Isolation Hospital. Three of these were intubated before being sent to the hospital, thereby saving valuable time.

What is the value of intubation, and when is it to be done? No comparison can be made between cases intubated and cases left alone. Probably the majority of cases of laryngeal diphtheria get well without operation. I have had 15 laryngeal cases of diphtheria the past year get well without operation. In seven of these the dyspnea was quite marked; but as long as they could sleep and were not getting exhausted, they were let alone. On the other hand, in six other cases delay was advised; but operation became necessary later, and all recovered. This indicates that the mortality need not be high in cases seen before the dyspnea gets extreme, even if they come to operation later. My rule has been to operate only when I thought that non-interference would be fatal in a very short time. All the cases but one have been seen in consultation. Except the hospital cases, only one has had a trained nurse. The idea prevails that some cases are too far gone for operation. Operation is never useless if stenosis of the larynx is present.

FOOD NOSTRUMS.¹

BY CHARLES HARRINGTON, M.D., BOSTON.

THE inventors and promoters of quack medicines have always shown the greatest commercial enterprise in pushing their wares, persuading the people that though feeling well they really are sick and in need of blood-purifiers, health restorers, spring medicines, kidney and liver cures and such; but in spite of their efforts, they have been unable to invade, as successfully as they would like, the ranks of the more intelligent, who hold quack medicines in deserved contempt. But this latter field is now being tilled by another class with enormous success, and many who would scorn to use a secret medicine are easy prey to the vendors of so-called health foods, which, in various forms and under fancy scientific-appearing names, are recommended for all ages from the suckling babe to the tottering nonogenarian. We have substitutes for mother's milk of greater nourishing qualities than the food given by Nature; blood-making preparations for the growing youth; foods of enormous potential energy for the adult worker; checks on tissue waste; preventives of rheumatism and calculus, and tissue builders for the aged; and aids to digestion for all. We have also special foods for the diabetic, the constipated, the dyspeptic and the convalescent, some of which might appropriately be advertised as sure preventives of longevity.

These foods are all successful from a pecuniary standpoint, for the public not only likes to be fooled but is encouraged in its folly by the unconscious connivance of the profession, who should no more permit

¹ Read before the Massachusetts Medical Society, June 8, 1897, and recommended for publication by the Society.

the use of secret foods than of secret medicines. And it is further encouraged in its folly by certificates and reports based on insufficient and unscientific data, signed by graduates in medicine who may or may not be creatures of the imagination, and, worse than all, may take the foods by order of the medical adviser.

In the course of my work during the past fifteen years I have had occasion to analyze a very large number of these foods, and am prepared to assert that I have yet to find a patent food which is not either a quite unnecessary and comparatively expensive substitute for ordinary food, or capable of producing harm rather than good.

The food nostrums may be divided into classes, as follows:

Some are simple frauds, incapable of producing harm, and equally incapable of exercising any of their advertised curative influences, but containing a reasonable amount of nutriment. There are many of this class, and two examples will suffice. A more or less popular food for dyspeptics, guaranteed "to instantly relieve acid or sour stomach, abnormal hunger, and sinking, all-gone feeling," "to prevent the injurious effects of ice-water," and "to relieve any trouble arising from indigestion," proves to be a very innocent meal, costing about ten times as much as corn meal or graham flour, made from the refuse of a popcorn factory, and quite free from added substances which might neutralize acids in the stomach. Another of this class, which at present is being well advertised, is a form of bread which is supposedly endowed with the property of self-digestion; it is said to be made with the addition of malt extract before being put into the oven,—a needless waste when one considers at what low temperature the ferment diastase is killed.

A second class includes such as are perfectly harmless and abundantly nutritious, but expensive and unnecessary, since the same dietetic results may be achieved quite as pleasantly and much more economically with the materials at hand in every kitchen.

In another group may be placed the infants' foods and substitutes for mother's milk. Most of the manufacturers of these preparations are willing to concede that Nature is a good guide to follow, and attempt to imitate her food; but they are not unanimous on this point, for there are those who, not satisfied with things as they have been created, have improved on Nature's methods and given us foods which they advertise as "superior to mother's milk." The infant foods may be divided into those made from cow's milk and those intended to be added to cow's milk, either to enrich it or to favorably affect its digestibility. Since it is impossible to reduce milk to a dry powder which, when treated with water, will again assume its original form, and since milk containing a normal amount of fat would tend, even if well concentrated, to quickly become rancid, and since another valuable constituent, the proteids, would become incurably altered in character in the process of drying, the manufacturers are driven to remove the (for their purposes) objectionable fat, and to add other substances foreign to milk, as cane sugar, malt sugar, dextrin and starch, so that a powder may be obtained, and then they impudently claim that their finished product, by virtue of this treatment, is either made to closely resemble human milk or to surpass it in nutritive value.

The other infant foods intended as additions to cow's milk are made from cereals, which should have no place

in the food of young infants, whose digestive organs are not yet ready for substances foreign to milk. When all that is needed to imitate natural food for infants is milk sugar, and water, and milk, which can be separated into cream, and skimmed milk, and when with these four simple substances one needs only to know how much of each is required for the mixture, how can we justify the use of the expensive substitutes which introduce foreign substances, starch, dextrin, malt sugar and cane sugar, into young stomachs which are doing well enough if they can digest what Nature intended they should? And not only do they introduce foreign matter, but unless they are fortified by milk or cream they furnish a very insufficient proportion of fat.

A fourth group may include those foods which are harmful to the particular class to whom their use is commended. Here we may place all the diabetic flours and biscuits and breads. What would be thought of a physician who should order for his diabetic patients unlimited sugar candy, dry crackers and white bread? No answer is necessary, but such a course would be not much if any worse than permitting them to use the commercial diabetic foods. Some years ago I exposed to the profession the character of all the diabetic foods in the market. Since that time I have examined such new flours as have appeared, but I have yet to meet one made from cereals which does not contain a liberal supply of starch, and most of them are as rich in it as whole flour.

The fifth and last group includes those which may act unpleasantly, injuriously or even dangerously to sick and well alike. Who would direct that a patient suffering from weak digestion and irritable stomach should be given a nauseous mixture of beef blood, sheep's blood and glycerine? Would a knowledge of the character of the ingredients tend to assist the patient in retaining and digesting it? Add now to the mixture some fruit juices or syrup. Is it thereby improved, or made more nauseous and repulsive? But this is not enough; in order that this food may be preserved indefinitely without the body, let us now add a substance which will also retard its digestion within the body and at the same time irritate the stomach, the kidneys and the bladder, namely, a liberal dose of salicylic acid. With this addition the mixture now resembles the animal arcana so much in demand for making blood in anemic persons, building up convalescents, furnishing strength to the weak and strong alike, and rescuing from the hand of death the sufferer from wasting disease. To this class belong also the canned and bottled clam broths, that waste product so poor in nutriment and so rich in chemical preservative. Such, also, many of the horde of alcoholic beverages masquerading under the magic name of Malt, with their freedom from diastase and richness in salicylic acid.

Such, then, are the patent foods so widely advertised in print and by the gratuitous distribution of sample packages—all unnecessary and expensive, some harmful as well.

We attempt to educate the people as to the desirability of purity in the common articles of food so that they may understand the dangers of adulteration, and then we leave them the helpless prey of the crafty medical food specialists. We ought rather to continue to teach them that it is to their physical and pecuniary advantage to avoid nostrums of all sorts, and that the proper feeding of children and the sick can be carried

out more intelligently, more beneficially and more economically with the food materials in common use, which need no fancy names and claim no medicinal virtues.

A RARE FORM OF OCCIPITO-ATLANTAL ARTICULATION.

BY GEORGE A. DORSEY, PH.D., CHICAGO, ILL.
Assistant Curator of Anthropology, Field Columbian Museum.

ABNORMAL conditions in the manner of articulation of the atlas with occipital bone are not uncommonly met with, and have been described in large numbers. The most frequent condition which is encountered is the bony union of the atlas with the occiput. This may be confined to ankylosis of the articular facets of the atlas to the occipital condyles, or part or all of one or both arches of the atlas may be involved, or the jugular processes of the occiput may be unusually long and join in bony union or articulate with one or both transverse processes of the atlas. These or similar abnormal conditions have been described by Lawrence,¹ Toynebee,² Hussey,³ Boxhammer,⁴ Turner,⁵ Schniffer,⁶ Grawitz,⁷ Zoja,⁸ Allen,⁹ MacAllister,¹⁰ and Slade.¹¹ The paper by Dr. Slade contains a careful review of the subject and describes eight cases. The paper by Professor MacAllister is perhaps the most valuable and contains very full references to the literature.

It is outside my purpose to discuss the causes of abnormal occipito-atlantal articulation or their frequency, and they are common enough, but rather to describe a peculiar form of articulation in which several points of interest are involved. But first a word in regard to the skeleton itself. It is one of many purchased by the Field Columbian Museum from Sr. Montez, of Peru, who found it along with others in a rock-tomb at Huaracundo, a small village near Cuzco, Peru. When received into the museum it had on the original wrappings of fibre rope and had never been opened. It was a good example of the mummy packs which come from that region, and may be considered as belonging to the Inca branch of the great Kechua stock. It may not be without interest to note in passing that these same Huaracundo rock-tombs have been very fertile in their yield of anatomical anomalies. Thus, of three mummy packs from the Montez collection from that region, one contained a skull in which the atlas was fused with the occiput, in the second the skull had been most skilfully and successfully trepanned in two places, while the third serves as the basis of this paper. Again, in a small collection of crania made by the writer in that locality in 1892, one was trepanned, another had the atlas joined to the occiput, while four

others showed the effect of disease by the presence in each skull of a large circular hole.

Turning now to the skull which directly concerns us, we may begin with the occipital bone. On the right side (see Fig. 1) the jugular process extends downwards and slightly backwards into a prolongation which measures 23 millimetres in length, and 17 millimetres in its greatest diameter. The process is somewhat compressed in a slightly oblique antero-posterior direction. On the anterior surface, toward its lower extremity, is a nearly circular articular facet which

FIG. 1.

measures 10 millimetres in diameter. The facet is concave from side to side. On the atlas (see Fig. 2) there is a corresponding facet on the posterior border of the right transverse process, which is unusually deep at this point. The facet is concave from above downwards and is rougher than that of the paramastoid process.

A reference to Fig. 3 shows that when the atlas is in place on the condyle it is perforce twisted slightly out of its normal position. There has been, as has already been said, a slight backward tendency in the growth of the process, but while it has been enough to escape

FIG. 2.

the superior surface of the transverse process and to avoid fusion with the atlas, it has not been sufficient to permit of the atlas retaining its normal position. As a result, the atlas makes an angle of about 20° to the sagittal plane of the foramen magnum. A compensatory change, however, has taken place in the odontoid-atlantal articulation, which permitted the head to be directed forwards and to be sustained in something like its original equilibrium at the same time. Referring to Fig. 2 again, it may be noticed that in the atlas a new articular surface for the odontoid process has been formed on the right antero-inferior surface of the

lateral mass, occupying the position normally occupied by the tubercle for the transverse ligament. The effect of this new condition can also be plainly made out on the odontoid process, where extended around on the

FIG. 3.

right side is an articular surface which corresponds to the lateral articular surface on the axis.

It may not be without interest to call attention also to the fact that the left transverse process is bifid, a condition not often met with. It can also be seen in Fig. 2 that the groove for the vertebral artery on the left side is almost bridged over by a spiculum of bone which begins near the middle of the posterior arch, and terminates half-way between the posterior border of the superior articular process, and the anomalous facet on the transverse process. There is also a small spine which begins along with the one just mentioned and is directed towards a similar process from the middle posterior surface of the superior articular process. These two spines probably would ultimately have united and formed a canal for the vertebral artery. There is also on each side just posterior to the vertebral foramen a rather large well-defined *supernumerary* foramen.

In regard to the form of atlanto-occipital articulation just described so far as I can learn, only two similar cases have ever been recorded. These are to be found in Testut,¹² and the paper, already mentioned, of Professor MacAlister.

The reference in Testut is as follows: "Je l'ai vue (l'apophyse paramastoïdienne) dans un cas atteindre 22 millimètres de longueur et s'articuler avec l'apophyse transverse de l'atlas à l'aide d'une facette ovale à grand axe transversal qui mesurait 10 millimètres de largeur sur 8 millimètres de hauteur."

The statement from MacAlister is this: "In the skull of an Egyptian this par-occipital process is a thick styliform column, 22 millimetres long by 11 millimetres thick, which ends in a flat facet that articulates with a similar facet on the transverse process of the atlas."

Although neither of these cases is exactly similar to the one I have just described, yet in a male skull from Ancou, Peru, a condition very similar to that de-

scribed by Professor MacAlister is present. Unfortunately we possess only the skull, so it is impossible to determine what was the nature of the atlas. But the left jugular or paramastoid process has extended downwards and backwards, and measures 10 millimetres in length and 15 millimetres in diameter. It terminates in an irregular circular facet which has an upward and backward inclination and is slightly and obliquely concave from side to side. The occipital bone shows a large amount of platybasic deformity.

In the second skull from Huaracundo, which I have already mentioned, the atlas is fused with the occipital bone through bony union of the condyles. The anterior arch remains free, as does the posterior, the latter, however, is incomplete. There is no abnormal development of the jugular process. The right vertebral foramen is very small, while that of the left side has no anterior border. The transverse processes are greatly undersized.

The fourth specimen is that of a male Kwakiutl from British Columbia. The condition is somewhat similar to the one just described. The atlas is ankylosed to the occipital bone through the condyles and superior articular surfaces. The jugular process of the left side is also united to the transverse process, as is the left half of the posterior arch, which is incomplete for about eight millimetres. The anterior arch is free for the greater part of its course. The left transverse process is bifid.

Reports of Societies.

MAINE MEDICAL ASSOCIATION.

THE FORTY-FIFTH ANNUAL MEETING, PORTLAND, JUNE 2-4, 1897.

FIRST DAY.

THE Association was called to order at 10.30 o'clock A. M., on June 2d, by the President, DR. D. A. ROBINSON, of Bangor. Prayer was offered by REV. H. L. BURRAGE.

After routine business, a report was received from the Special Committee on Membership. An interesting feature of this report was the fact, that out of 400 registered regular physicians to whom application blanks were sent upon recommendation of members of the Association, only 110 availed themselves of the privilege; of this number 67 appeared before the Censors during the sessions and were elected to membership.

The Treasurer's Report showed a balance on hand, with no indebtedness, of \$1,783.59.

DR. S. J. BASSFORD, of Biddeford, reported

TWO COMPLICATED NERVOUS CASES IN THE SAME FAMILY.

One of these, in a child of ten years, was diagnosed as "amyotrophic lateral sclerosis"; the other, occurring in a sister aged twelve years, was regarded as hysteria, with symptoms simulating those of the sister first affected. Both had marked chorea.

DR. C. D. SMITH, of Portland, read a paper on the BACTERIAL FEATURES OF TYPHOID, WITH SPECIAL REFERENCE TO PATHOLOGY AND DIAGNOSIS.

In the abstract presented, the writer aimed to show,

¹² Testut: *Traité d'Anatomie Humaine*, third edition, *Osteologie*, p. 125.

first, the inutility of direct intestinal antiseptics, in a disease due to an absorbed toxin, produced for the most part outside the intestinal tract, and, secondly, to present a description and explanation of the sero-diagnosis. He gave the results of 105 blood tests from 12 cases of typhoid. Six cases showed the reaction from the seventh to eleventh day. In two, it was delayed until the seventeenth day in one, until the thirteenth in the other. From one a reaction was obtained with blood taken on the evening of the second day of fever, subsequent examination of blood from this case during convalescence showed an absence of the reaction for days at a time with reappearance at irregular intervals. Of the remaining three cases two have shown no reaction; one gave agglutination with only enfeebled motility, although a typical typhoid case, with characteristic symptoms. All the examinations were by Johnston's modification of Widal's test.

RESUSCITATION AFTER SUBMERSION

was the title of a paper by DR. HIRAM HUNT, of Greenville.

AFTERNOON SESSION.

The Association met at 3 o'clock.

Prof. F. C. Robinson, of Bowdoin College, was elected to honorary membership in recognition of valuable contributions to the scientific meetings of the Association.

THE PRESIDENT'S ADDRESS

was then delivered by DR. D. A. ROBINSON, of Bangor. Among its recommendations it urged the appointment of a committee to take into consideration the abuse of medical charities in the State, to bring the State Association into closer touch with the various county societies by the appointment of delegates to these societies, and to invite to a participation in the proceedings of the Association the State Board of Registration in Medicine, with a suggestion that the homeopathic and eclectic members might perhaps be turned from the error of their ways.

A special committee was appointed to take into consideration these recommendations, and later reported advising action in accordance with the President's suggestions. Those relating to charities and the county societies were unanimously adopted, but the Association evidently had no desire to engage in missionary work and refused to adopt that relating to the Board of Registration.

The address was an able review of the progress of the Association in its relations to medicine during the year past, and topics of interest to the profession were touched upon in a witty and forceful way.

The question of Medical Inspection of School Children was brought prominently to the attention of the Association, but no action was taken expressive of the opinion of its members.

DR. J. N. MERRILL, of Skowhegan, presented a paper on

PREVENTIVE MEDICINE, OR NOTES ON SEWER AIR POISONING, AND SANITATION.

DR. W. K. OAKES, of Auburn, read a paper entitled

THE TECHNIQUE OF AMERICAN SURGERY.

It presented a careful analysis of the methods in vogue in New York, Philadelphia and the Johns

Hopkins Hospitals so far as related to the room and furniture, the preparation and care of instruments, sponges, dressings, sutures and ligatures and to the preparatory technique as applied to both patient and surgeon.

Great stress was laid upon the constant, painstaking attention to details, which explains, with skill in operative procedures, the success of American surgery.

A paper on

HIP-JOINT DISEASE,

by DR. HENRY H. BROCK, of Portland, made prominent the point that whatever the predisposing or underlying causes, hip-joint disease is a local disease of local origin. The outline of treatment was, extension and counter-extension for months after all inflammatory symptoms have disappeared. Absolute rest in bed, early evacuation of pus to prevent extension of the suppurative process and the wearing of a fixation appliance for a year or more after the patient gets up on crutches.

EVENING SESSION.

DR. O. ST. C. O'BRIEN, of Rockport, Mass., read a paper on

ADDISON'S DISEASE,

regarding it as a disease of the sympathetic nervous system caused by tuberculous, cancerous or other degeneration of the supra-renal bodies. The treatment advised was mainly symptomatic.

A series of five-minute papers followed on various phases of the

MANAGEMENT OF LABOR,

by four Portland physicians.

DR. ADDISON S. THAYER spoke upon the "Medicinal Treatment," laying special stress upon the value to be derived from the use of ether and morphia, not only as aids to the normal progress of labor but as preventives of complications.

DR. STANLEY P. WARREN treated of the "Antiseptic Treatment," claiming that the parturient state demanded the same kind and degree of antiseptics as major surgery.

DR. FREEMAN E. SMALL presented the subject of the "Manual and Postural Treatment" as obviating recourse to more severe operative procedures.

DR. JAS. B. O'NEIL discussed the question of "Instrumental Treatment."

He thought the rule to apply forceps when the head stopped advancing a better one than to apply them when it stopped receding.

In the discussion DR. C. G. ADAMS, of Portland, reported a case in which the head did nothing but recede with the pains. The condition was, after delivery by forceps, found to be due to a cord less than six inches in length.

For an hour following the adjournment the members enjoyed an informal reception in the form of a "smoker."

SECOND DAY.

The first paper was read by DR. F. N. WHITTIER, Director of the Gymnasium at Bowdoin College, on

PHYSICAL TRAINING AND ITS THERAPEUTIC VALUE.

The paper demonstrated by reference to details of work in modern gymnasia how the aim of physical training was attained by adapting it to individual needs,

supplementing it by careful attention to the rules of personal hygiene.

THE FREQUENCY OF ERRORS IN MEDICAL CERTIFICATES.

DR. W. E. ELWELL, surgeon of the National Soldiers' Home at Togus, read a paper as above.

STATIC ELECTRICITY.

The advantages of this force as a remedial agent in nervous and muscular diseases unattended by structural changes were presented in a paper by DR. W. T. GOODALE, of Saco.

ACCURACY AND HONESTY OF PURPOSE IN THE PRACTICE OF MEDICINE.

DR. G. M. WOODCOCK, of Bangor, read a paper on this subject.

AFTERNOON SESSION.

Dr. D. E. Baker, of Newtonville, Mass. and Dr. A. P. Richmond, of Dover, N. H., were introduced as delegates from their respective societies and presented their greetings to the Association.

The annual election of officers resulted as follows:

President, Wallace K. Oakes, Auburn; First Vice-President, E. A. Thompson, Dover; Second Vice-President, G. M. Woodcock, Bangor; Corresponding Secretary, H. B. Palmer, Farmington.

Board of Censors: W. B. Moulton, Portland; F. C. Thayer, Waterville; W. J. Maybury, Saco; E. M. Fuller, Bath; Alfred King, Portland.

Committee on Publication: The Recording Secretary (*ex officio*); H. H. Brock, Portland; Geo. C. Parker, Winthrop; W. T. Goodale, Saco; G. M. Elliot, Brunswick.

Business Committee: E. J. McDonough and A. S. Gilson, of Portland.

DR. A. G. YOUNG, of Augusta, Secretary of the State Board of Health, read a paper on

THE LATER RESULTS WITH DIPHTHERIA ANTITOXIN.

The discussion brought out the gratifying fact that antitoxin was being used with greater freedom and in much larger dosage than a year ago, with correspondingly excellent results. The writer presented the latest results of the Pediatric Society's second report, and from connective reports of the German Hospitals, the latter showing 14.7 per cent. mortality for a year, against an average of 26.5 per cent. before antitoxin came into use.

At 4 o'clock the Association adjourned and became the guests of the physicians of Portland. Cars were taken for Riverton, a summer garden six miles from the city, where the Association and visiting delegates were entertained by a band concert, and a lunch served in the Casino.

EVENING SESSION.

Returning to the city, the Association again met at 8 o'clock, and the Annual Oration, a most scholarly and instructive discourse on

THE RELATION OF MENTAL DISEASE TO GENERAL MEDICINE.¹

was delivered by DR. EDWARD COWLES, of the McLean Asylum, an Honorary Member of the Association.

Following the oration PROF. F. C. ROBINSON, of Bowdoin College, read a paper on

NEW METHODS OF DISINFECTION.

This paper dealt with the practical application of formaldehyde, for gaseous disinfection.

One quart of wood alcohol would furnish gas enough for each 2,000 cubic feet of space; more should be used rather than less as saturation of the atmosphere is absolutely essential.

The writer was conservative, as to the penetration power ascribed to the gas by various manufacturers of generating lamps and thought from his own experience that further experimentation would be necessary to determine accurately this point. So far as laboratory results go it was infinitely superior to sulphurous acid.

CLOSING SESSION, FRIDAY.

This, as usual, was devoted to business. Reports were received from delegates to other medical societies, Visitors to the Maine Insane Hospital, the Medical School of Maine and the Portland School for Medical Instruction.

The report of the Necrologist gives the deaths during the year of Osgood N. Bradbury, Norway; Andrew J. Fuller, Bath; Thomas A. Foster, Portland; Francis E. Hitchcock, Rockland; Daniel Moody, Clinton; John O. Webster, San Diego, Cal.; Wm. Lawrence Dana, Portland. Drs. Foster and Fuller were ex-Presidents of the Association.

The Board of Censors made a final report.

Appointments were recommended as follows:

Visitors to the Maine Insane Hospital: Addison S. Thayer, Portland; J. L. Bennett, Bridgton; W. P. Giddings, Gardiner.

To Portland School for Medical Instruction: C. B. Sylvester, Harrison; C. H. Cumston, Brunswick.

To Medical School of Maine (two years): R. D. Bibber, Bath.

Delegates to American Medical Association: B. B. Foster, Portland; Aug. S. Thayer, Portland; J. K. Phillips, Bangor.

Delegates to New Hampshire Medical Society: J. D. Cochrane, Saco; Ambrose H. Weeks, Bar Mills.

Vermont: F. E. Small and J. B. O'Neill of Portland.

Massachusetts (1898): D. A. Robinson and Jas. F. Smith of Bangor.

Rhode Island: J. B. Thornton, Boston; E. M. Plummer, Charlestown.

Connecticut: Chas. A. Ring and I. E. Kimball of Portland.

New Brunswick: John A. McDonald, East Machias; F. A. Chandler, Addison. Maritime Medical Association, Daniel Hennessey, Bangor; L. H. Wheeler, South Brewer.

New York State Medical Association: E. E. Holt, Portland; G. M. Woodcock, Bangor.

The selection of an Orator was postponed.

The appointment of Delegates to County Medical Societies was left to the President and Secretary.

The date of the next annual meeting will be June 1, 2, 3, 1898, and the place of meeting Portland.

AUGUSTUS P. CLARKE, M.D., of Cambridge, Mass., was chosen an honorary president of the Section of Obstetrics and Gynecology of the Twelfth International Congress, held in Moscow, August 19th to 26th.

SPLENECTOMY.

JONNESCO, of Bucharest, made at the Twelfth International Medical Congress a contribution of great importance to surgery upon this subject.

During recent years the literature of splenic surgery has been small, as our knowledge of the subject has been passing through the experimental stage. Enough cases of splenectomy, however, had by the time Jonnesco began his work, in 1896, been accumulated in surgical literature to show that splenectomy for the hypertrophied leukemic spleen was uniformly fatal; while the hypertrophied spleen of malaria, and the wandering spleen had been removed with comparatively frequent success.

Jonnesco had noticed the steady improvement in the statistics of splenectomy for the hypertrophied spleen of malaria. He collected 36 cases, with a mortality of 18, or 50 per cent., but found on examination by dates that, from 1887 to 1896, there had been 25 cases, with 8 deaths, or 31.7 per cent.; and that from 1891 to 1896 there were 15 cases, with 3 deaths—a fall in mortality to 15.4 per cent. This fall in mortality is due undoubtedly to two causes: improvement in technique, including asepsis; and a more intelligent choice of cases for operation. Among the contraindications established by the experience of previous operators have been (1) profound cachexia, (2) extensive adhesions, (3) great size of the organ, (4) leucocythemia.

With all these contraindications Jonnesco's experience leads him to agree, except that of the size of the spleen. Péan, Vulpian, and Adelman have considered that splenectomy, in order to be successful, should be limited to spleens of a weight of less than three kilogrammes. Jonnesco's experience does not lead him to agree with these authors, for in four out of his twelve operations he removed spleens weighing over three kilogrammes, the largest weighing 5.750, with success.

The indication for operation Jonnesco considers to

be, the failure of medical treatment to relieve the pain, disability and beginning cachexia; and his experience has shown that these symptoms, as well as the general health, rapidly improve after splenectomy. He considers the undue prolongation of medical treatment both useless and dangerous; for as long as the patient is the subject of splenic hypertrophy, cachexia progresses, and the prognosis of the operation becomes worse.

The prognosis will vary according to whether the operator is dealing with an adherent, fixed, mobile or dislocated spleen.

With regard to the effect of splenectomy upon the blood and system, Jonnesco has had the same result as previous observers, finding that a great increase in the number of red blood-corpuscles resulted, sometimes beginning immediately after the operation, sometimes after a short period of diminution. The white corpuscles also increase, and with relatively greater rapidity than the red ones; so that during a certain period of varying length there is a temporary leucocytosis.

These conclusions of Jonnesco's are certainly given additional weight by the extent of his experience, for between February 3, 1896, and August, 1897, he had performed splenectomy 12 times, 11 times for malarial hypertrophy, and once for hydatid cyst. His mortality was three, or 25 per cent.; and at the time of his writing one of his patients had not yet left the hospital. The three deaths occurred in extremely unfavorable cases. In all of them the spleen was very large and universally adherent. In freeing the spleen in one case the pleura was opened in two places, and in another the diaphragm was torn so that it had to be sutured.

With regard to operative technique, Jonnesco lays stress upon the operator's standing on the patient's right, the median incision, complete exposure of the vault of the diaphragm, the rupture of adhesions at the expense of the abdominal walls, in order to avoid traction on, and rupture of the spleen, the section of adhesions between two ligatures, the section of each vessel of the pedicle between two ligatures. Wounding the splenic capsule should be avoided, and complete hemostasis secured before closure of the abdomen. Strong compression with an elastic bandage should be employed.

A temporary rise of temperature, which frequently follows splenectomy, may be due to a recrudescence of malarial poisoning, or to a bronchitis, which frequently ensues. No mention is made of the anæsthetic employed.

Jonnesco concludes his paper as follows: "The comparatively slight danger of splenectomy, its excellent results in malarial hypertrophy, the disappearance of the symptoms of cachexia after the operation, lead me to propose extirpation of the spleen even in cases where the spleen is comparatively small and the local symptoms not severe, as preventive treatment against malarial cachexia. I am led to this con-

clusion by Laveran's discovery that the spleen is the source from which the hematozoa of malaria are distributed to the body in the blood stream. Each discharge of hematozoa coincides with the rise of temperature, and hypertoxicity of the urine.

Jonnesco's paper, a copy of which we have just received, is illustrated by excellent cuts of several of his patients before and after operation, and of the organs removed. It is a contribution of distinct value to surgical science; although the advanced position taken by him with regard to the removal of slightly hypertrophied spleens as a preventive of malarial cachexia will probably be regarded as somewhat too radical for immediate adoption by the profession.

THE NEW TUBERCULIN.

IN spite of the great expense of Koch's new preparation, T. R., a constantly growing number of valuable reports are coming in, chiefly from the German clinics. It is clearly evident that a very much larger number of observations, and extending over longer periods of time, must be made before we can arrive at any definite conclusion as to the efficiency of the new remedy. Nevertheless, certain evidence of value is already at hand.

In the *Deutsche Medicinische Wochenschrift* for August 19th appears a series of clinical articles concerning the use of T. R. as applied to the treatment of tuberculosis in its various forms. Professor Dautrelepoint, of Bonn, gives a list of fifteen cases suffering from lupus and treated by the new method. In the treatment of these cases the directions as given by Koch were followed as closely as possible, namely, to begin with an injection of one-five-hundredth of a milligramme of the preparation, with a gradual increase of the dose about every second day, care being taken to avoid an elevation of more than half a degree in temperature. Dautrelepoint found that higher temperatures than desirable were often induced, even by a gradual increase of the dose. In general he made it a principle never to repeat the injection until increased temperature had entirely disappeared.

From his experience he concludes with Bassenius¹ that the age of the T. R. is probably of influence in relation to elevation of temperature. The largest dose used in this series of cases was four milligrammes, being the thirty-eighth injection. In addition to the rise of temperature, in certain cases headache, lassitude, vertigo and sensory disturbances in the limbs were noted. In general the patients increased in weight during the treatment. The injections were usually well borne. There was an occasional complaint of pain at the seat of injection which often showed some infiltration. The diseased area showed a comparatively quick formation of skin over the ulcers. The hypertrophic lupus, in a measure, disappeared, and scar tissue took its place. The swollen lymph-

glands decreased in size during the treatment; some, however, suppurated and demanded incision.

Dautrelepoint concludes that T. R. has a favorable effect upon lupus, and is of the opinion that it has a greater curative action than the old preparation. He warns against a too rapid increase of the amount of the dose because of the liability to fever, which always has a more or less deleterious effect upon the patient.

In a second paper, Dr. Bruno Leick reports a series of fifteen cases of lung tuberculosis in which the new tuberculin was used. At first the back between the scapulae was used as the point of injection, which was later changed because of the pain occasioned when in the lying position. Of the fifteen cases treated a decided improvement was noted in but two, and in these the suspicion is raised that an equally good result might have been attained under the ordinary routine treatment.

Professor Rumpf approaches the question of the therapeutic value of T. R. with an equal or greater scepticism. Rumpf found that the injection in most cases was painful and frequently followed by an inflammatory infiltration of the skin. A case of interest is one in which Koch's maximum dose (twenty milligrammes) was injected without temperature reaction. Later, however, a marked rise of temperature came on, much like that noted in the use of the old tuberculin, the outcome of which for the patient must be regarded as ominous. Rumpf reports a number of cases, both favorable and unfavorable in their course, and reaches conclusions of importance which we reproduce in part.

First, the new tuberculin, in doses as recommended by Koch, frequently causes painful inflammatory infiltration of the skin which is slow to heal.

Secondly, by gradual increase of the injected dose it is possible to reach the maximum dose with but slight reaction, but it does not follow that a more or less serious fever may not supervene upon the later injection of a previously well-borne amount.

Thirdly, it appears from this that the reaction or failure to react is inconstant under similar conditions.

Fourthly, the reaction frequently consists in general manifestations, such as frequency of the pulse, vertigo, pain, etc., as well as in increase in temperature.

Fifthly, it is doubtful whether Koch's maximum dose produces immunity in men.

Sixthly, should its immunizing power be shown lacking, the advantage of the new tuberculin over the old would consist merely in containing more toxic substance.

Seventhly, it is desirable to proceed with much caution in primary and localized tuberculous processes of the lungs.

It will be seen that Rumpf's attitude is one of extreme scepticism.

Following the report of a case of acute tuberculous inflammation of the middle ear during a new-tuberculin treatment, Dr. Richard Müller, of Berlin, warns us of the possible danger of the preparation, inasmuch

¹ *Deutsche Med. Woch.*, 1897, No. 28.

as in his case there was some evidence to show that the process in the ear was rendered more active by its use.

Dr. Herzfeld, of Berlin, furnishes a report of the treatment of seven cases of larynx tuberculosis. Here, again, results are discouraging, since in but one case was a decided improvement noted as probably due to the use of tuberculin. The opinion is expressed that in all the other cases more would have been accomplished by the usual local treatment. In any case Herzfeld rightly maintains that whether or not T. R. be used local treatment should never be omitted.

A paper perhaps of more interest than those hitherto considered, as coming from the directing physician, Dr. Baudach, of a sanitarium for tuberculosis, concludes the series of reports. Baudach was extremely careful in the choice of patients and in his system of injection. Twenty patients in all were treated, most of them suffering from tuberculosis of the lungs. Excepting for slight symptoms, such as those already alluded to, there was for the most part no evil effect from the injections, nor was there a single case of abscess formation. Baudach reports at considerable length twelve cases in which the treatment might be regarded as entirely, or almost entirely completed. As a result of his observation of these cases, he arrives at a much more hopeful judgment of the working of T. R. than those previously expressed. He found the treatment in general to be followed by decidedly good results and productive in a number of cases of a more rapid improvement than would otherwise have been the case.

It must be remembered that these patients were under the most favorable possible conditions for improvement; nevertheless, a careful reading of Baudach's paper leaves the impression that, apart from the favorable surroundings, a distinctively curative action is to be attributed to the tuberculin.

So far as it is possible to draw conclusions from the various cases to which allusion has been made we may say, first, that the new preparation has proved itself decidedly useful in lupus and probably of limited specific action in visceral tuberculosis; and, secondly, that at present it should be employed only in conjunction with other recognized methods of treatment.

THE DIMINISHING DEATH-RATE IN NEW YORK CITY.

DURING the week ending September 11th there was a slight increase in the mortality of that city, which is probably to be attributed to the high temperature prevailing in the latter part of the week. The number of deaths reported was 746, representing an annual death-rate of 19.44 per thousand of the estimated population; against 732, representing an annual death-rate of 19.09, in the preceding week. There was one death from sunstroke. As the weather conditions up to the advent of the short hot wave have been extremely favorable, the public health has con-

tinued good and the mortality exceptionally low. During the week ending August 28th the number of deaths reported was 716, a decrease of 34 from the previous week.

It is interesting to note that the Bureau of Vital Statistics, in its mortality report, September 4th, for the first time places the population of New York above the two million mark, its estimate being 2,000,916. In the week ending September 11th the population is placed at 2,002,031. An increase in an estimated population is one way of diminishing a death-rate.

Typhoid fever, in the mortality from which there is usually some increase at this season of the year, appears to be on the decrease, as the number of deaths from it in the week ending August 28th was 12, while in each of the two succeeding weeks there have been but seven deaths from it. In the week ending September 11th there were only 11 deaths from diphtheria, which is the lowest mortality from that disease for a very long time. The deaths from diarrheal diseases decreased from 107 in the week ending August 28th to 89 in the week ending September 4th, while the total number of deaths in children under five years of age, in whom the vast preponderance of mortality from this cause occurs, amounted to 335.

On September 8th President Wilson, of the Health Department, sent to the mayor a communication in which is shown the diminishing death-rate in the city during the past five years. It contained the following table, which gives the deaths, with the annual death-rate, in the first eight months of each year.

Year.	Estimated Population.	Deaths, Jan. to Aug. Inclusive.	Annual Death-Rate.
1893	1,758,010	31,982	27.3
1894	1,809,353	29,397	24.4
1895	1,879,195	30,599	24.5
1896	1,934,077	30,307	23.5
1897	1,990,562	26,866	20.2

This decline in the death-rate of seven per thousand is equivalent to a saving of 13,933 a year, and is attributed by President Wilson to an improved sanitary condition in the city, especially as regards pavements and clean streets.

The *Montreal Gazette* of September 4th, in an editorial on the Address in Public Medicine by Dr. H. M. Biggs at the recent meeting of the British Medical Association, says: "What intelligent work is capable of accomplishing for the public health was well illustrated in the paper read by Dr. Biggs." After quoting statistics covering the death-rate in New York during the past twenty years, it continues: "There could not possibly be a better illustration of what 'authorities on sewers' can do. Not only do they make it possible for the people to live longer, but they reduce the suffering from diseases, and from that fact enable the masses to better provide for themselves. Such a condition of affairs is a credit to the capacity of New York's Health Department, which promises to make the city a rival of London in being among the healthiest of the great centres of population of the world. It is a lesson and incentive to the public health departments of other cities."

MEDICAL NOTES.

VIOLENT REMEDIES.—Professor Brouardel, in a recent lecture related the following case: A man had a pharyngeal abscess, so deeply seated that his medical attendant was afraid to meddle with it. One night a burglar broke into the house, and on the sick man calling for help tried to throttle him. The abscess burst, deluging the burglar with pus and causing him to beat a rapid retreat. His intended victim experienced instant relief and made a rapid recovery. — *Medical Record*.

THE SURGEON-GENERAL OF THE NAVY.—Surgeon-General Tryon of the Navy has just completed his term of service, having made a highly honorable record during the thirty-five years in which he has been connected with the medical department of the Navy. It is confidently expected that President McKinley will, in recognition of his meritorious service, renew his appointment; as, if reappointed, he will be able to retire on September 29, 1899, with the rank and pay of the highest grade he has filled.

DISPENSARY ABUSE.—We are glad to note that the failure of the governor to sign the bill regulating dispensary practice, and doing away with many of its present evils, has not thrown cold water upon the efforts of the advocates of the bill. On the contrary, it has acted as a decided stimulant to the fight against dispensary abuse. Medical societies are exerting their power against it; medical periodicals have discussed it *pro* and *con* and from every conceivable standpoint. We are pleased to see that the crusade has become so general and strong, and that this strength presages the ultimate doing away with, to a degree at least, of a practice which is not only sapping the profession of its income but its dignity. — *Albany Medical Annals*.

YELLOW FEVER.—During the week ending with this number of the JOURNAL, yellow fever in New Orleans and Mississippi has, contrary to the predictions of the sanitary authorities, continued to spread slowly, and gain a moderate footing. In New Orleans the type of the disease has been mild; up to September 15th there had been one death in 14 cases. The epidemic at Ocean Springs has continued; and Dr. Wasdin of the Marine Hospital Service is ill with the disease at that place. On September 14th there were 15 cases at Biloxi. In the hamlet of Berkly, La., out of a population of 25 persons only three had failed to take the disease. Several cases have occurred at Mobile, Ala., and Dr. Guiteras of the Marine-Hospital Service apparently admits the possibility that the disease may become epidemic in that city. The period of the year offers a reasonable guarantee against a serious disturbance.

BOSTON AND NEW ENGLAND.

A FREE HOSPITAL FOR BAR HARBOR.—A movement is on foot for the establishment of a free hospital at Bar Harbor, Me.

BEQUEST TO A HOSPITAL.—By the will of the late Charles T. Wilder, of Wellesley, \$5,000 was left to the Mary Hitchcock Memorial Hospital at Hanover, N. H., to found a Charles T. Wilder Free Bed.

CEREBRO-SPINAL MENINGITIS IN MASSACHUSETTS.—The Massachusetts State Board of Health has recently sent a circular letter to physicians with a view of ascertaining the extent of the epidemic of cerebro-spinal meningitis, which has prevailed this year, and the prevalence of this disease in private practice. Six questions with regard to the disease are asked, and a description of the epidemic form of the disease and its various types is given. Replies are to be sent to Dr. W. T. Councilman, Harvard Medical School, Boston, who will make a report upon the subject.

THE STATE BOARD OF HEALTH ADMONISHES PHYSICIANS.—The Massachusetts State Board of Health has found it necessary to remind physicians of the reciprocal duties they are expected to perform in return for the furnishing of antitoxin, facilities for the bacteriological diagnosis of diphtheria, etc., by that body. In a circular recently issued they are reminded that the antitoxin is furnished gratuitously, to be used in the cases of persons unable to pay for it, and on condition that a description of the case and the effect of the remedy be furnished the board of health in return. The State Board of Health will withhold future supplies of antitoxin from local boards which fail to secure compliance with this rule. Care in the storage and distribution of antitoxin are also enjoined upon the local board, and instructions in the use of the diphtheria culture tubes are given. With regard to the examination of sputum, the State Board will receive for examination only specimens forwarded in the receptacles furnished by the board. Leaky receptacles endanger all persons who handle them. Material sent by mail will be rejected. Cover-glasses for the examination of blood with reference to malarial infection, with instructions for their use, will be sent on application to any part of the State. Examination of cultures, sputum, etc., will be made gratuitously by the board's pathologist, if the conditions of transmission are complied with, and not otherwise.

NEW YORK.

WHAT A LOW DEATH RATE MEANS.—In the management of ambulance cases the ambulance first arriving at the spot where an individual requires immediate medical or surgical aid is supposed to take the patient to the nearest hospital; but a recent case where a man had his skull fractured in the vicinity of Roosevelt Hospital and was taken by an ambulance of that hospital a long distance to Bellevue, where he died in a few hours, has called renewed attention to the practice of the large private hospitals maintaining an ambulance service, all of which receive more or less assistance from the public funds, of sending dying patients, sometimes taken directly from their own wards, to the public hospitals. Naturally, such transfers are not, as a rule, beneficial to the patient; but it

is highly desirable that the death-rate in such hospitals, which depend to a greater or less extent on private contributions for their support, should be kept as low as possible, in order that in their annual reports a favorable showing may be made to their patrons.

DEATH FROM IVY-POISONING.—A death is reported from Chester, near Middletown, N. Y., from rather an unusual cause, the effects of ivy-poisoning. The patient was a female, sixty-nine years of age, who came in contact with the plant early in July. Her whole system seemed to be profoundly affected by the poison, and death resulted after two months of great suffering.

Correspondence.

THE BRITISH MEDICAL ASSOCIATION.

MONTREAL, September 6, 1897.

MR. EDITOR:—This meeting was an event in many respects unique in the medical history of this continent. Never were more elaborate preparations made for a series of medical meetings, or greater pains and expense lavished for the comfort and entertainment of guests and members. It was the first time that a meeting of the British Medical Association had been held outside the British Islands; and in order to comply with the obligations imposed upon the Association by statute and by its by-laws, it was found necessary to hold the first part of this annual meeting in London, England.

About nine hundred members were present who registered their names; of these only about a hundred were from the United Kingdom. There were representatives from New Zealand, Australia, India, and other foreign countries. It speaks well for the interest manifested in the Association, that so many were present from abroad; and it is creditable to the profession of the Dominion that out of eight thousand physicians (a constantly increasing number) scattered through that vast country, a large part of whom (unfortunately for them) take no medical journals and attend no medical meetings, there should be such a considerable proportion members of the British Medical Association, whose meetings they can so seldom attend.

Of invited guests (mostly from the United States) who registered their names, there were present about two hundred and forty. The public meetings were also attended by a considerable number of the citizens of Montreal and by medical students from the various universities. Some of the meetings—notably the General Meeting on the afternoon of the 31st ult., in Windsor Hall—were honored by the presence of Lord Aberdeen, Governor-General of the Dominion; the Mayor of Montreal; Sir Adolphe Chapleau, Lieutenant-Governor of the Province of Quebec; Sir Donald Smith, now Lord Strathcona and Mount Royal; Sir James Grant, Prof. Charles Richet, delegate of the Faculty of Medicine, Paris, France; Lord Lister, and others. A pleasant occasion was the laying of the foundation-stone of the Nurses' Home at the Montreal General Hospital on Thursday by Lord Lister; all the dignitaries above mentioned were present and participated with speeches.

Nothing could exceed the hospitality extended to the members of the British Medical Association and its guests by distinguished citizens of Montreal. On Thursday, the Mayor of Montreal entertained a large party at lunch upon the mountain. Lunch was served in the observatory, from which the Mayor's guests commanded a splendid view of the city and across the valley of the St. Lawrence to the hills beyond.

On Wednesday afternoon a garden-party was given on the grounds of the Royal Victoria Hospital; it was attended by a large number of the members of the Association and ladies. The Governor-General was present, accompanied

by Lord Lister. The excursion on Wednesday afternoon to Lachine Rapids was participated in by over five hundred persons, who went by special train to Lachine and came down the Rapids in the steel steamer *Sovereign*. This, and a number of excursions around the city and island, were free to members and invited guests.

A Ladies' Reception Committee devoted their energies to providing for ladies visiting Montreal entertainment during the morning when the discussion in the Sections was going on. On Tuesday afternoon, Miss Roddick, sister of the President of the Association, gave a tea in the Art Gallery, and a large number of guests and members attended.

A great number of excursions were planned to take place before and after the meetings, and the various railroad and steamship lines reduced their fares one-half to the members of the Association and their families. Among these excursions were trips to Quebec and back; down the St. Lawrence and up the Saguenay and back; to Halifax, N. S., and return; to St. Johns, N. B., and return; to Ottawa and return; to Toronto and return, etc. A great many of those attending the meeting availed themselves of these opportunities to enjoy at little cost the finest Canadian scenery at a season when nature is especially attractive, the mid-harvest time of Canada.

On Wednesday afternoon, after the General Meeting, the degree of LL.D., was conferred by McGill University on Lord Lister (a fitting recognition of his services to surgery); on Prof. Charles Richet, of the University of France; on Sir Walter Foster; on Sir William Turner; on Dr. Henry Barnes; on Prof. Michael Foster; on Dr. W. H. Gaskell; on Mr. Christopher Heath; on Dr. Alexander MacAllister; on Dr. R. Saundby; and on Dr. Claud Wheelhouse.

I cannot presume on this occasion to enumerate a tithe of the excellent papers presented to the Association at the General Meetings and at the various Sections. There were eleven Sections, at which for four days papers were read and discussions held between the hours of 9 A. M. and 1 P. M. We would have been glad to have taken in all. It was truly an *embarras de richesse*. In all these Sections there were distinguished representatives of general medicine, or of some special department of medicine or surgery whom it was worth a journey to Montreal to see and hear. Fortunately, the *Daily Journal*, published by the Association, and distributed during the morning hours to attendants of the various Sections, supplied in a measure the need felt of having the principal papers in full and an epitome of all the discussions. This is a feature of these meetings which I do not remember ever to have seen in any other Medical Convention; certainly not at the annual meetings of the American Medical Association. The cost of these *Daily Journals* must have been large; it was, I believe, paid out of the funds of the Association.

On Tuesday evening there was a *Conversazione* at Laval University, where an address was given by Prof. Charles Richet, in French, "On the Work of Pasteur and the Modern Conception of Medicine." Those who were fortunate enough to get seats where they could hear this address (it was delivered apparently *impromptu*, without notes or manuscript) had a rare treat.

The address of Dr. Roddick, President of the Association, on the afternoon of Tuesday, on "Canada, its Medical Life and Resources," was full of interesting information respecting the climatic conditions, health resorts and spas, the medical schools, etc., of the Dominion. At this meeting, Dr. O'Donnell, the delegate of the Government of Manitoba, in behalf of the Premier of Manitoba, invited the British Medical Association to hold its next meeting in Winnipeg. He stated that this city was young; thirty years ago it was but an outpost of civilization; fifteen years ago the stream of emigration began to turn in that direction; and out of the wilderness has been formed the province of Manitoba with a population of 300,000, and the city of Winnipeg has grown up, containing a population of between 40,000 and 50,000. It is not likely that the invitation will be accepted!

The work of Wednesday comprised the Presidential Ad-

dress of Dr. Stephen MacKenzie, "On the Influences which have determined the Progress of Medicine during the Preceding Two and a Half Centuries"; the address of Mr. Christopher Heath, F.R.C.S., "On the Teaching of Surgery"; the address of Dr. LaChapelle, "On the Progress of Sanitation in Canada"; the Presidential Address before the Section of Pharmacology and Therapeutics, "On Past and Present Views as to the Actions of Medicines"; Dr. Watson Cheyne's address before the Section of Pathology, "On the Progress and Results of Pathological Work"; the Wednesday afternoon address of Dr. Osler, published in the *Boston Medical and Surgical Journal* for September 2d, etc.

I must not omit to mention the able and original paper by Dr. Maurice Backe, of London, Ontario, "On Mental Evolution." Dr. Backe, in a few incisive paragraphs under a dozen heads, has indicated the standpoint of modern psychology, as I believe. Some, however, will be astonished to learn that "the musical sense does not appear in the individual before the average age of about twenty years"; that it has existed less (probably) than 5,000 years in the race; that the human moral nature "is congenitally and permanently absent in four per cent. of all individuals"; and that "it cannot have existed in the race more than 10,000 years at the most." Equally novel are some of this author's views as to the future development of mind. "So-called telepathy and clairvoyance seem to be specimens of nascent faculties. As also the phenomena often named spiritualism. . . . To me these are not cases in which outside agents are acting on or through a human being, but are cases in which a given human being has faculties which are not commonly possessed. . . . Whether such faculties shall grow and become common . . . will depend on the general laws of natural selection, and upon whether the possession of the nascent faculty is advantageous or not to the individual and to the race."

The address of Dr. Malcom Morris "On the Rise and Progress of Dermatology" was a masterly *résumé* of the history of Cutaneous Medicine, in which due credit was given to such American dermatologists as Fox, Boikley and Duhring.

On Wednesday there was a large flocking to the Surgical Section to hear the eloquent address of Christopher Heath, and the discussion on Appendicitis, in which participated Drs. Jordan Lloyd of England, Sir William Hings-ton of Montreal, Dr. C. B. Ball of Dublin, Dr. H. O. Marcy, and others. Dr. Ball's division of acute appendicitis cases was a very practical one, that is, into three classes: the fulminating, those with abscess formation, and those in which the symptoms were such that the progress of disease could not be exactly ascertained. It is in this latter form that the question of operation is very difficult to decide.

The address by Dr. Mitchell Banks, in Windsor Hall, on Thursday, "On Military Surgeons, Ancient and Modern," was full of interesting information and was listened to by a large audience. The excellent army medical service of to-day was contrasted with that of former generations, but no mention was made of the splendid and unique organizations for surgical aid during the late Civil War in the United States (a singular and infelicitous omission).

The work of Friday in the various Sections was of unusual interest, and I regret that I cannot dwell on any of the topics presented. In the Section of Medicine, the subject of Cholelithiasis was discussed; in the Surgical Section, the Surgery of the Bile Passages. In the Section of Pharmacology and Therapeutics, the discussion on Diuretics was opened by Dr. Barr of Liverpool, and ably continued by Dr. Marshall of Cambridge, when a very important paper was read by Dr. H. A. McCallum of London, Ontario, "On Behring's Serum in Diseases not caused by the Klebs-Löffler Bacillus." The effect on consumption, cancer, pelvic inflammation, lupus, etc., was discussed. A favorable action was reported in the case of lupus. The theory suggested was that the serum increased the internal secretions. In connection with this paper, Dr. Bazin's "On Diphtheria Antitoxin" was read. He regarded it as important that

the strength, date of production, etc., should be stated on the label. He believed that "a clinical suspicion" afforded sufficient grounds for the use of a serum; bacterial examination should follow this.

In the Section of Bacteriology, Dr. V. Moore made a communication on "The Nature and Differentiation of Infective Diseases of Swine in the United States." He spoke also of swine diseases in Europe, seeking to group the diseases. Dr. W. H. Welch maintained that Metchnikoff's bacillus of hog cholera was not that of American hog cholera. He referred to the extreme difficulty of differentiating the pathogenic organisms in hog diseases. Dr. Boyce read a paper on "The Tubercle Bacillus in Milk," and discussed the communicability of tuberculosis from the lower animals to man. Tubercle bacilli have been found in the milk of cows with and without disease of the udder. Milk from tuberculous cows had been proved to be infectious.

In the afternoon meeting in Windsor Hall, Dr. Hermann M. Biggs of New York, delivered a masterly address "On Public Medicine," of which I will venture on no synopsis, as it will probably be published in several journals.

I think that I may say, fearless of contradiction, that the delegates and invited guests from the United States (such as took part) were not behind their British confrères in the merit of their contributions to the meetings. I felt on many occasions that our men were to be congratulated on the good points which they made and on the favorable impression which they gave. I think that the members of the Association from Great Britain and other foreign countries will go home feeling more respect for American physicians and surgeons, and that the bonds of union and friendship between the medical men of the several nationalities will be greatly strengthened. Such gatherings are cosmopolitan.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, AUGUST 28, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from					
				Infectious diseases.	Acute lung diseases.	Diphtheria and croup.	Typhoid fever.	Diphtheria and croup.	Diphtheria and croup.
New York . . .	1,868,060	716	293	11.14	14.42	14.28	1.68	2.80

Deaths reported 3,471; under five years of age 1,411; principal infectious diseases (small-pox, measles, diphtheria and croup,

cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 876, diarrheal diseases 613, consumption 338, acute lung diseases 196, diphtheria and croup 116, typhoid fever 81, whooping-cough 37, scarlet fever 13, cerebro spinal meningitis 9, measles 7.

From whooping-cough Chicago 9, Philadelphia and Washington 5 each, New York, Brooklyn and Pittsburg 4 each, Cincinnati and Cambridge 2 each, St. Louis, Boston and Everett 1 each. From scarlet fever Philadelphia 6, New York 3, Boston 2, St. Louis and Baltimore 1 each. From cerebro-spinal meningitis Washington 3, Malden 2, New York, Philadelphia, Lynn and Somerville 1 each. From measles New York 4, Philadelphia, Brooklyn and Fall River 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending August 21st, the death-rate was 28.7. Deaths reported, 6,058, diarrheal 1,367, measles 138, whooping-cough 74, diphtheria 42, scarlet fever 34, fever 34.

The death-rates ranged from 12.0 in Huddersfield to 52.6 in Wolverhampton; Birmingham 42.9, Bradford 31.6, Derby 27.8, Gateshead 26.2, Hull 45.2, Leeds 29.9, Leicester 35.6, Liverpool 38.3, London 24.2, Manchester 39.2, Newcastle-on-Tyne 29.5, Nottingham 32.0, Portsmouth 25.4, Sheffield 33.2, Swansea 17.2.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, SEPTEMBER 4, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from:					
				Infectious diseases.	Acute lung diseases.	Diarrheal diseases.	Typhoid fever.	Diphtheria and croup.	
New York	1,848,000	732	335	19.74	12.40	12.46	.38	3.50	
Chicago	1,019,216	366	145	31.56	10.64	25.52	3.36	3.98

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 11, 1897.

F. L. ROGERS, surgeon, detached from the Boston Navy Yard, October 4th, and ordered to the Norfolk Navy Yard.

J. L. NELSON, medical inspector, detached from the Norfolk Navy Yard, September 30th, and ordered to the Boston Navy Yard, October 4th.

RECENT DEATHS.

ISAAC HOLDEN STEARNS, M.D., M.M.S.S., died in Cliftondale, September 6, 1897, aged seventy-two years.

DR. JOHN C. BOLLES, of Montville, Conn., one of the oldest members of the New London County Medical Association, died at his residence September 11th, aged eighty-one years.

DR. JULES BERNARD LUYIS, the eminent alienist physician, member of the Academy of Medicine and officer of the Legion of Honor, died recently in his sixty-ninth year at Divonne-les-Bains. Born in Paris in 1828, resident medical officer at the hospital in 1853, and graduated as M.D. in 1857, Dr. Luyis became in 1862, physician to the Salpêtrière and the lunatic asylum at Ivry (Seine). His best-known work, "The Brain and its Functions," was published in 1878. Dr. Luyis was for a long time professor at the Salpêtrière, afterwards at the Charité, where he devoted himself especially to the study of the phenomena of hypnotism.

BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Maine Medical Association, 1897, Vol. XII, Part III.

Annual Report of the Board of Health of the Health Department of the City of New York for the year ending December 31, 1896. New York. 1897.

Recherches Expérimentales et Cliniques sur les Nerfs Sécrétaires des Larmes. Par le Dr. M. Campos. Paris: Henri Jouve, Imprimeur de la Faculté de Médecine. 1897.

A Text-Book of Diseases of Women. By Charles B. Penrose, M.D., Ph.D., Professor of Gynecology in the University of Pennsylvania; Surgeon to the Gynecae Hospital, Philadelphia. Illustrated. Philadelphia: W. B. Saunders. 1897.

Phthisis Originating in Colorado. A Case of Double Pulmonic Murmur, with Diastolic Thrill. Interrupted Respiration, a Study of Certain Physical Signs of Diseases of the Chest. A Case of Pulsating Pleurisy. The Physical Signs of Acute Bronchitis. By J. N. Hall, M.D., Denver, Col. Reprints. 1897.

Atlas and Essentials of Bacteriology. By Prof. K. B. Lehmann, Chief of the Hygienic Institute in Würzburg, and Dr. Rudolf Neumann, Assistant in the Hygienic Institute in Würzburg. With 63 chromo-lithographic plates, comprising 558 figures, and numerous engravings. New York: William Wood & Co. 1897.

THE HUMAN FOOT IN ART.¹

BY E. H. BRADFORD, M.D., BOSTON.

WHEN the sculptor Hiram Powers pointed with pride to the anatomical excellence (in his eyes) of his "Greek Slave" in contrast to the anomalies in the classic masterpieces, he argued himself lacking in true artistic spirit.

Correct commonplace is not preferable to what is beautiful even though the latter is defective in minor details.

It is certainly hypercriticism to lay undue stress upon small trivialities where the whole commands admiration.

No true Romanist kissing the bronze toe of St. Peter pauses to examine the modelling of the foot; and any one who looks at the anatomical defects of Fra Angelico's "Coronation of the Virgin," or Botticelli's "Madonna" at the Louvre, robs himself of time which might be more enjoyably employed.

And yet a study of great Homer nodding has its interest and value, and need not detract from our true admiration.

Any one whose attention has been called to the subject of the shape of the human foot will find it of interest to examine the feet in a collection of statues. While there is some variation in the work of different sculptors, it will be found that the types can be classed under three heads: first, Barbaric and Egyptian type; second, the Classical type; third, the neo-Classical and Modern.

The first may be considered the type of the bare-footed or sandal-wearing people; the second, sandal- and cothurnus-wearing people; and the third, those of the races that have worn shoes.

The Barbaric and Egyptian type is, as a rule, badly modelled, with the exception of some of the best of Egyptian sculptures, where modelling in some instances is carefully done.² The various statues of Rameses II, B. C. 882, the famous wooden statues of the Fourth Dynasty, B. C. 3700, are all excellent types of this class. Under this head can also be placed Assyrian specimens and the works of early Indian, Burmese, Siamese, Chinese and Japanese art, as well as the few crude figures from Africa, Mexico and Alaska, and also the archaic Etruscan, Cyprian, and the early Greek statues.³ This class is characterized by the lack of divergence of the axes of the feet in standing figures, that is to say, by the parallel position of the axes of the feet, by the straight inner edge of the foot, and by the straight and uncrumpled condition of all the toes. In the Egyptian and early Greek art, where there is any attempt at careful modelling of the toes, the first toe is separated from the second, and in most instances the second toe is represented as somewhat longer than the first.

The second, or Classical, type is best represented by

¹ Read before the American Orthopedic Association, Washington, D. C., June, 1897.

² A mummy may be seen in the Museum of the Louvre, illustrating the care with which the straightness of the toes was preserved; each toe, including the fifth, was separately wrapped. In the British Museum an unwrapped mummy of an Egyptian official of the Eleventh Dynasty showed the straight first toe seen in the statues of the Egyptian type.

³ In the Greek statues on the Sacred Way at Branchidial Caria, Asia Minor, B. C. 560, the fifth toe is uncrumpled; in all subsequent Greek statues the peculiarities mentioned of the Classical type are found. In the Museum of Northern Antiquities in Copenhagen a round beach-stone may be seen on which is cut two footprints; the inner edge is straight; the toes, including the fifth, are straight. It is of unknown antiquity.

the famous foot of the Hermes, supposed to have been made by Praxiteles. The characteristics are well marked. The line of the inner edge of the foot is always straight, except that there is a slight curve between the head of the metatarsal and the ankle. There is a separation between the first and second toes; the second, third, and fourth toes frequently diverge from the axis of the foot at an angle of at least thirty degrees and are parallel to each other; the fifth toe is represented as short and crumpled, and is placed back of the base of the other toe; the outer edge of the foot curves behind the fifth toe to the middle of the foot. The angle of divergence of the standing foot is slight. This type is seen in all Greek and Roman statues, with but little variation, the straight direction of the first toe being universal as well as the crumpled condition of the small toe. The curling of the small toe appears in Greek art after the sixth century B. C., and may be said to be universal since in all art influenced by Greek tradition.

The foot in modern sculpture as well as in that of the Renaissance is copied largely from the classic. The peculiar distortion of the small toe is universal; and, in addition, the fifth toe is often placed even farther back on the outer edge than in the best Greek type.

Wherever the sculptor has endeavored to leave classic models and to copy nature, he has produced a curious medley in distortions. This is particularly the case in recent sculpture, where deviation of the greater toe is extremely common. Modern sculptors, neglecting the classic tradition, copy imperfect models. The outward divergence of the second, third and fourth toes from the median line is copied from the Greek and exaggerated, representing the fourth toe as straight and uncrumpled—impossible in modern shoe-wearing models. The modern sculptor copies also the curved line on the outer side of the foot, which is seen in Greek and in Roman art, especially exaggerating the classic curve from a desire to present a curve of beauty.⁴

Certain modern sculptors place the feet diverging from each other at a greater angle than is seen in the Egyptian and Classical periods.

The Greek showed such a mastery in surface anatomy, the Barbaric type is so crude, and the Modern type so impossible, that the first and readiest impulse would be to accept at once the foot of the Hermes of Praxiteles and show it as a model for all sculptors, as is done in many art schools; but any inquiry as to which of these types is the most correct should rest on a firmer basis than a hasty conclusion.

To form an opinion in the matter it is necessary to bear in mind the deformities of the feet caused by the footwear in the different periods referred to, and to study the foot unaffected by shoes. Of most importance is the common distortion of the great toe, which is known as *hallux valgus*, which results from the yielding of the great toe to outward pressure at its extremity. The corresponding inward distortion of the small toe from shoes is also often seen. A

⁴ The number of modern sculptors who give to their statues *hallux valgus* is too great to be enumerated in a short paper. Even as careful an artistic anatomist as Gérôme, in his "Bellona" gives this defect. The sculptors in the earlier part of the century were more careful than the modern French school, but they frequently modelled the deviating great toe (Thorwaldsen, Canova). This is also true of the brilliant school at the time of Louis XIV and of the Renaissance (Donatello, Michael Angelo).

crumpled and crowded condition of the toes known as hammer-toe, or curling downward of the toe, results from too short shoes or from the backward pressure exerted by the front of the shoe on the extremity of the smaller toes. Another affection of the toe is extremely common in persons whose feet have been compressed by shoes, namely, a weak or powerless condition of the muscles which prevents active muscular use at the phalangeal joints.

Some distortion of the toes is seen at a comparatively early age. The examination of the feet of a number of children indicates that in communities where shoes are worn the feet, even in young children, differ in shape from the normal shape of the foot; the separation of the great toe from the second toe is lost at an early age; the fifth toe is crowded towards the fourth and the muscular strength diminishes even at the age of three. Some distortion of the foot in modern cities may be said to be universal, and sculptors seeking perfect models for the feet find no model with uninjured feet.

SHAPE OF THE FOOT UNAFFECTED BY SHOES.

If the foot of a young infant is examined, it will be seen that there is muscular power in the movement of all of the toes. The great toe can voluntarily be drawn to the inner side, and the fifth toe can be drawn to the outer side by voluntary muscular exertion; the toes can be flexed readily. The second toe is, when stretched to its full length, frequently longer than the first; the third is of the same length of the first; the fourth is somewhat shorter; and the fifth, though shorter, is but slightly so, and is readily moved, flexed, extended as well as abducted, by muscular action. None of the toes remain permanently curled, though when in a relaxed condition the terminal phalanx drops somewhat and the smaller toes curl. A separation between the first and second toes is normal when the muscles are active, and the great toe is drawn to the inner side frequently. The line of the extremity of the toes presents a gradual curve, the greatest convexity being at the tip of the second toe. There is no twist inward of the fifth or small toe. The curved line connecting the proximal end of the toes is a curve similar to that formed by the extremities of the toes. The line of the inner edge of the foot is always straight, except when there is contraction of the muscles when the great toe diverges to the inside.

Adult feet that have not worn shoes present shapes similar to that of infants, except that in the ordinary wear and tear of locomotion the skin is thickened, and some curling downwards of the smaller toes is frequently seen, owing to the strength of the plantar muscles. For this reason the second toe is not usually seen longer than the first, as the position which it assumes is usually less straight, it being less strong. The inner edge of the foot is always straight; but in people who walk actively, the great toe and its metatarsal becomes developed in strength and size more than is seen in infants. The foot is longer relatively to its width; the fifth toe, being the weakest, is very susceptible to slight changes from lateral pressure, and where slippers have been worn or loose shoes, a slight twist of the terminal phalanx of the fifth toe is frequently seen. The widest part of the foot is at the cross-line drawn across the toes and including the fifth toe, as in the Egyptian foot. The foot somewhat re-

sembles that depicted in the Egyptian sculptures, except the toes are parallel, and the second, third and fourth do not diverge from the long axis of the foot, and in the position of rest the smaller toes are more flexed than in the Egyptian statues.

An investigation of the deformities of the foot due to footwear leads to an inquiry into the different kinds of foot-covering. No proof is needed to show that the modern shoe distorts the foot, and an examination of any collection of shoes (as the excellent one at the Museum of the Cluny and the remarkable historical exhibit of shoes at the Chicago World's Fair) shows that shoes of the Middle Ages distorted the feet nearly as much as the modern ones.⁵ Distorting shoes were probably not as universally worn as at present, and were perhaps used chiefly by the leisure classes. But pointed-toe shoes were fashionable even among the Egyptians. In fact, it may be said that as soon as man ceases to need the free use of the foot in hunting, bread-earning, marching or locomotion, he attempts to use the shoe as a means of ornamentation, according to his own fancy; as an evidence of distinction and a mark of freedom from base toil — like the compressed foot of the Chinese lady.

Footwear can be classified as follows: boots or shoes, where the whole of the foot is covered; slippers, where the front of the foot is covered, both holding the front by the upper, covering the dorsum of the foot; and sandals, where an inter-toe strap connected with cross-straps holds the sole.

Although boots, shoes and slippers vary in shape according to period and fashion, with the exception of the boots of laboring men and jack-boots, ornamental shoes were almost always pointed, though at the period of the Thirty Years' War, and at a time in the seventeenth century, square-toed shoes were occasionally seen for men. Medieval and Oriental slippers do not retain the heel, and allow the foot to slip backward without crowding the front of the foot forward.

Sandals furnish a protection to the sole, and are secured to the foot by some form of thong or strap. The oldest form of sandal seen in sculpture is the Assyrian,⁶ which was retained by a strap around the great toe connected with straps from the sides of the sole and behind the heel. In the Egyptian sandal a thong passing between the first and second toes, from the middle of the front of the sandal over the dorsum of the foot, was connected with thongs from the sides of the sandal. This sandal is the most common type, and resembles the modern Japanese and the modern Mexican and South American sandal. The ancient Toltec sandal was furnished with two thongs, one passing between the first and second toe, and the other between the third and fourth. The modern Somalis wear a sandal with a thong split so as to admit the second toe, leaving the other toes free. The early Etruscans wore a sandal with cross-straps, the front one passing from the sole of the sandal, between the first and second toes, over the second, third and fourth toes, where it is secured to the sandal, leaving the first and fifth toes free, the other toes being secured under a strap.⁷

In all these forms of sandals, no pressure is exerted upon the small toe; but in a form of sandal with a

⁵ This is also seen in the sculptured tomb monuments of the Middle Ages.

⁶ Collection at the Peabody Museum, Harvard University.

⁷ This is seen in the rare terra-cotta tomb effigy of the early Etruscan period (uninfluenced by Greek art) in the British Museum — showing a sandal differing entirely from any seen elsewhere.

front, a cross-strap seen in the Orient for the insertion of the front of the whole foot, a certain amount of pressure is exerted on the side of the little toe, as in a slipper. This strap, however, is as loose as the cross-strap in snow-shoes. In the Greek sandal, however, a cross-strap or straps were connected by lacings to be tightened in such a way as to be more firmly held to the foot. The forms varied greatly. In most a single inter-toe strap existed to be caught in the cross-straps. In later sandals, however, the inter-toe strap was omitted, a reminder surviving conventionalized in the shape of the sole, which preserved a slight depression at the front of the sole between the first and second toes. The Greek and Roman sandal gave freedom to all the toes except the little toe, which was crowded by the tight cross-strap, as well as by oblique straps, which in some forms of sandals passed backwards from the sides of the front of the sandal to the instep, raising and crowding the little toe and the side of the first metatarsal. When this was snugly laced, an inter-toe thong became unnecessary, as the pressure on the little toe and the top of the foot prevented the foot from slipping forward.

This form of footwear can be easily imagined, if we suppose a low bicycle shoe, with the tip removed, leaving all the toes except the small toe free. A sandal of this sort was perhaps not developed in the early period of Greek history; but, judging from sculpture, the cothurnus of the late Greek and Roman period differed but slightly from that of the Classical period.

The ancients wore at times beside the sandal a loose covering like a moccasin, which did not affect the shape of the foot. Footwear of this sort would develop the shape in the foot seen in the *Hermes of Praxiteles*, crowding the small toe, giving the full length of the fourth, third and second toes (from the free and strong development of these toes), allowing a straight first toe and the slight inward curve on the inner edge of the first metatarsal at its proximal end, from the pressure of the oblique strap, and also the outward curve on the outer edge of the foot, as the chief pressure of the oblique strap came upon the little toe and not on the metatarsal. The inter-toe strap accentuated the separation of the first and second toes and the deviation from the axis of the foot of the smaller toes. This slightly distorted foot was seen in the models studied by the Greek masters.⁸

The dominating influence of Greek art explains the fact that the shape of the foot has been copied since

then by all true sculptors who have accepted Greek art as its fountain source.

In the Renaissance, where models were used by the great masters in painting and sculpture, the deformity of the great toe following the use of the shoes which crowded the first toe outward is commonly depicted, and in sculpture is occasionally seen. In modern French sculpture, among the realists this defect, the well-known *hallux valgus* of the model, is added to the classic defect, namely, an exaggerated difference between the fourth and fifth toes, and exaggerated rounding of the outer edge of the foot. Modern sculptors frequently also give a greater angle divergence to the axes of the feet in the standing figure than is seen in Classical statues, and much greater than in Egyptian or Barbaric figures. In this, too, the modern artists are copying defective models to the detriment of their art.

It can, with a certain amount of justice, be argued that, when a conventional use has been sanctioned for a long period of acceptance without violating the laws of beauty, it has justified its existence by a right of pre-emption, and that it is hypercritical to object to it. The argument hardly applies to a deformity, and would at once seem inadmissible, if urged by a Chinese artist in defence of the beauty of the "golden lilies," as Chinese poetic fancy terms the deformed Chinese ladies' feet. The deformities here mentioned differ in degree, but not in kind, from that accepted by usage in China; they are also distortions of nature.

There is a healthy tendency in modern art to revolt against what seems classic convention, and to copy nature; but, to do this, the artist needs thorough knowledge to enable him to escape preselecting as a standard the deformity observed in his own experience.

The taint of the corseted and high-heeled, weak-ankled *grisette* injures every modern art exhibition, even when the ideal is attempted. The sculptor who moulds "immortal forms" should not perpetuate deformity. There should be no *Zolaism* in sculpture.

Few, even among artists, realize how common it is to find defects immortalized in masterpieces. The wry neck of *Alexander the Great* may be allowed in a portrait statue; but it would be an error to give to the statues of all heroic generals twisted heads. Crumple-footed divinities, out-toed demigods, demigoddesses and weak-ankled national heroes cannot but offend the fastidious, when seen in lasting marble and monumental bronze.⁹

The normal foot resembles a combination of the Greek and Egyptian sculptured foot. It is straight on the inner edge, without the slight curve along the base of the first metatarsal; the fifth toe is parallel to the other, is not crumpled or twisted, and is not placed far back of the line of the other; the outer edge is but slightly curved, and does not bulge between the fifth toe and the ankle. The toes are flexible, and when at rest do not project stiffly, as in the Egyptian statues, but are slightly flexed, especially the smaller toes.

⁸ The defects in drawing the human foot seen in pictures are not alluded to here as fully as could be done in a longer paper. Less care is given to modelling in pictures than in sculpture. In brief, it may be mentioned that the defects here mentioned are more common in the paintings, even of the old masters, than in sculpture. In the gallery at Amsterdam a picture by *Goltzius*, A. D. 1600, depicts a dying *Adonis* with the feet sole forewards in the foreground and displaying double *hallux valgus* of an aggravated type. *Rubens* has never thrust his errors so directly upon the spectator; but his faults in this particular are fully as grievous, as is shown in his book of design in the *Musée Plantin* in Antwerp and in almost all his paintings. *Michael Angelo*, *Titian*, *Tintoretto*, *Raphael*—all show both the crowded fifth toe, and frequently *hallux valgus*.

⁸ An examination of Greek and Roman footwear, as seen in sculpture, is made difficult from the fact that in many instances the sandal is conventionalized. A great variety is also found, from the moccasin-like foot-covering shown in the fragments from the *Parthenon* to the elaborate sandals of the Roman emperors. A sandal is to be seen in the late Greek statue of *Ariadne*, found in *Roma Vecchia* and now in the British Museum, showing side loops for a cross thong over the base of the toes and crowding the fifth toe, leaving the thong to the imagination. The sandal of the statue of *Jason*, at the *Louvre*, shows the indentation in the sole opposite the space between the first and second toes, where a thong would be attached, but not only is there no inter-toe thong, but the sandal is apparently to be kept in place without one by the side leathers over the instep. A peculiar sandal is seen in the group of the Roman period, in the *Louvre*, called "*Mars and Venus*," in which a depression is delineated, allowing the longer toes to drop to a lower level. The Roman sandals in the Museum of the *Cliny* (found near the *Rhine*) and at the Museum in *Munich* show a straight inner edge which would have satisfied a North American Indian; and the sandals depicted in the Greek votive tablet in the British Museum would have been acceptable to a modern Japanese. The bronze statuette of the youthful *Bacchus*, in the *Payne King* collection in the British Museum, shows the side compression of the inner edge of the foot and of the little toe without a cross toe-strap, while the statue of *Hadrian*, also in the British Museum, the *Diana Chasseresse* and the *Seated Philosopher* of the *Louvre*, as well as many other statues, show the compression by lacing including the cross toe-strap.

There is not much vitality in the contention that this foot is not as graceful as that presented by the Greek artist, in the mind of any one who has seen normal feet uncrumpled by shoes or distorted by toil; but even if there were more, although it is the province of the artist to furnish us with beauty as he sees it, he must find it within the lines of truth, and it is as true now as in Shakespeare's time that

"Above the art we add to Nature
Is the art which Nature gives."

DESCRIPTION OF CUTS.

FIG. 1. Diagram representing the Greek (*a*), Egyptian (*b*), and modern type (*c*) of sculptured foot.

FIG. 2. (*a*) Foot changed by modern shoe. (*b*) Infant's foot, toes extended. (*c*) Infant's foot, toes at rest. (*d*) Child's foot, showing beginning changes from shoes.

FIG. 3. Types of sandals: (*a*) Mediterranean single-thing sandal. (*b*) Chaldean sandal secured to first toe. (*c*) Somali sandal secured to second toe. (*d*) Toltec sandal secured to second and third toes. (*e*) Early Etruscan sandal secured to second, third and fourth toes.

FIG. 4. Greek sandal with inter-toe thing, causing divergence of toes; cross straps crowding the little toe; and an oblique strap pressing on the inner edge of the first metatarsal and binding the foot at the mid-tarsal joint.

FIG. 5. Drawn from the fragment of the statue of Apollo from Phigaleia (in the British Museum), showing the compression of the small toe.

FIG. 6. Drawn from the Hermes of Praxiteles found at Olympia.

FIG. 7. Egyptian seated statue (British Museum).

FIG. 8. Japanese feet, showing the lack of crowding of the fifth toe seen in Greek and modern art.

FIG. 9. From a picture of Sir Joshua Reynolds showing the hallux valgus distortion of the great toe in addition to the crowded little toe.

HEMORRHAGE ATTENDING THE EXTRACTION OF CATARACT.¹

BY O. F. WADSWORTH, M.D., BOSTON.

THE exact cause of hemorrhage attending the operation for extraction of cataract has remained an unsolved riddle. But our very ignorance as to the cause makes such cases interesting. The condition of the eyes, and the age and health of the individuals who have been the subjects of this accident, have presented very decided differences; and probably the cause is not always the same. The cases observed in my own practice do not throw much light on the nature of the affection, yet they may serve with others as material to lead eventually to a satisfactory solution.

CASE I. A man eighty years of age had been under observation for two or three years with slowly maturing cataract. During this time he had been repeatedly examined, and, aside from the lenticular opacity, no defect found in the eyes. After an interval of some months he came again to the hospital; and a somewhat hasty examination showing the cataract, in the left eye at least, mature, he was admitted and etherized. When the speculum was introduced, it was noticed that the perforating veins of that eye were larger than usual, but the tension was not specially abnormal, although perhaps somewhat increased. Puncture and counter-puncture were in the scleral edge, the summit of the flap in the cornea. Almost immediately after the section was finished a small, threadlike stream of blood was seen to flow upward across the lens from behind the lower border of the pupil, followed quickly by larger quantities which caused extensive prolapse of the iris and gaping of the wound. The eye was bandaged, and it subsequently atrophied. A few months later, when the patient desired operation on the other eye, it was found to have lost perception of light.

CASE II. A sailor, seventy-five years of age.

Cataract in both eyes. Right eye: sight failing one or two years; counts fingers at 17'. Left eye: sight failing four or five years; cataract quite dense; projection faulty; a number of superficial and several deep veins running backward from near the corneal edge, and along its upper half forming an anastomosis about $\frac{1}{2}$ " from the limbus; anterior chamber of good depth; tension normal.

October 8, 1877. Extraction, left. Puncture and counter-puncture in sclera, the summit of the flap in clear cornea. Large iridectomy before division of capsule, a small amount of cortical following spontaneously the withdrawal of the cystotome. Brief and unsuccessful attempt to remove a portion of capsule by forceps. The speculum was raised so as not to press on the globe and a moderate sized nucleus and some cortical was readily pressed out, but a considerable amount of cortical remained and several attempts to remove this by pressure through the lower lid were only partially successful. At a moment when no pressure was being made blood welled up from behind the iris, filled the anterior chamber and flowed out of the wound. After a few minutes the anterior chamber became partially free from blood and a bandage was applied.

The following day the anterior chamber was again filled with blood and a clot distended the wound. The clot gradually protruded until the corneal flap was folded backward by it, and the whole cornea became densely infiltrated. The man was discharged at his own request on October 27th.

CASE III. A man of forty-five years, always well and strong. Right eye, normal and with good vision. Left eye, mature cataract. He said this eye had been struck by a fork when he was a child, but he experienced little inconvenience at the time and the sight had been failing only a year. There was no scar to be perceived. Tension was normal; pupil active; he counted fingers at one to two feet and projection was good.

February 3, 1893. Simple extraction. The speculum removed as soon as the corneal section was completed. The lens was removed without difficulty, the pupil immediately became round and even. But within a few seconds, while the eye was still open, there was a sudden and great prolapse of the iris attended by severe pain. The lids were closed. Shortly there was a large gush of fluid vitreous, followed soon by a smaller gush and this by a stream of blood which trickled down the cheek. The man was told of the condition of affairs, enucleation was advised and done. There was no excessive bleeding from the enucleation and the healing was normal.

Although in this case the man's history so far as known was good, it is a significant circumstance that he is reported to have died suddenly of apoplexy within a year.

CASE IV. A man of sixty-nine. Good general health; mature cataract of two and a half years' duration in the left eye. Size and dilatability of pupil good; projection normal. Eight years before, a cataract had been removed from the right eye by an experienced oculist, followed by sloughing of the cornea and panophthalmitis.

April 8, 1895. Simple extraction under cocaine. Section smooth, wholly in the cornea. Ecchymosis of conjunctiva where grasped by fixation forceps. Speculum removed after capsulotomy. The nucleus

¹ Read before the American Ophthalmological Society.

and a considerable amount of soft cortical removed without special manipulation. The iris prolapsed, but went back into place with slight stroking of the cornea, leaving a round, clear, central pupil. There was no apparent tendency to gaping of the wound or dilatation of the pupil, although the globe seemed a little more rounded out than usual. Eserine, one-tenth per cent., dropped into the eye, a light pad wet with solution of bichloride laid over the lids, and the bed rolled aside, to wait for a while before the bandage was applied. Some fifteen minutes later the patient complained of severe pain; the lower lid was found to be covered by a large amount of fluid vitreous and the iris extensively prolapsed in the gaping wound. A bandage was applied; he was given a subcutaneous injection of morphia; he had a chill.

Three days later the prolapse had flattened, the lower part of the anterior chamber was of good depth, there was no blood in the pupil; but after another four days the prolapse had increased and a fibrous membrane was adherent to it and overlapped the upper part of the cornea. This membrane was snipped off with scissors; the prolapse was removed as completely as possible, and only recurred slightly afterward.

The bandage was continued till April 25th. May 2d there was a small amount of blood in the anterior chamber and a membrane tinged with blood stretching across the pupil; very gradually the pupil was drawn upward. There was no tenderness. Tension was slightly diminished. Twice the membrane in the pupil was divided to some extent by a knife needle, but the opening closed quickly; each time there was a small hemorrhage into the anterior chamber, which was readily absorbed. Until the time of his discharge, May 30th, there was perception of light.

CASE V. An American woman, seventy-five years old, of good general health. Cataracts in each eye, which had been recognized for three years. The front of the eyes appeared normal; there was a good depth of the anterior chambers; the irides were active. Tension normal. There was sufficient vision in the left eye to enable her to find her way about with some difficulty. Projection good in both. The lenses presented numerous striæ, with less opaque areas between them; and when the pupils were well dilated with homatropine, a view of the fundus of the left eye (very imperfect, but enough to show that there were at least no very gross changes) was obtained.

Several days later, March 12, 1897, simple extraction of the right eye under cocaine. The section was wholly in the cornea and quite smooth. The speculum was removed as soon as the section was completed. T-shaped division of capsule, without difficulty and without displacement of the lens. Just at the end of the capsulotomy the patient complained of some pain, but she did not move and neither then nor at any time during the operation was there any special contraction of the orbicularis or of the ocular muscles. On placing the spoon on the lower part of the limbus it was noticed that the eye was quite firm and the probability of hemorrhage was mentioned. A rather large, slightly brownish lens, followed by a very small amount of cortical, was expelled by moderate pressure, with no prolapse of the iris. Almost immediately the wound was widely distended by vitreous and there was complaint of severe pain. The lids were closed, and in one or two seconds a large amount of apparently healthy vitreous oozed out between them. A pad wet

with solution of bichloride was laid over the lids and a subcutaneous injection of morphia given. A few moments later blood was trickling out between the lids and running down over the cheek. The condition was explained, enucleation advised and agreed to. By the time etherization was complete a clot had formed in the wound so firm that it was not disturbed during the removal of the eye. The enucleation was attended by no unusual hemorrhage. Healing was normal. The eye was hardened and divided. Its cavity was filled with blood-clot, which was situated in part beneath the extensively detached choroid. The few sections examined showed no apparent disease of the choroidal vessels.

Of these cases the first may be regarded as suspicious before the operation. Too much reliance was placed on examination made some months before, and hence the examination at the time of operation was imperfect. When the discovery of the large perforating veins and doubtful tension was made the patient was already etherized, and on the whole it seemed better to go on and operate. Had cocaine anesthesia then been known it would still have been possible to make further examination of the functions of the eye; or had we then realized as we do now the comparative unimportance of complete maturity of the cataract, the other eye might have been operated on instead, with perhaps better results.

The second case was certainly an unfavorable one. While the record does not mention the fact, I do not doubt that under such circumstances I operated only on the urgency of the patient. Whether even then it was justifiable may perhaps be a question. The other three cases presented no unfavorable symptom.

In none of the cases was there anything in the behavior of the patient to contribute to the result — no undue restlessness, no squeezing of the lids or sudden contraction of the ocular muscles. Possibly this may not be wholly true of the fourth case, the only one in which the hemorrhage did not occur during or immediately after the operation. This patient also was quiet so long as he was under observation; that there was no spasmodic contraction during the fifteen minutes that elapsed between the time that he was moved to one side and his complaint of pain cannot positively be asserted.

Nor was there any want of smoothness in the course of the operation except in the second case. Even in this case the introduction of forceps to seize the anterior capsule did not stir the lens from its position, and although the manipulation for removal of cortical was somewhat prolonged it was not excessive; and this case was the one in which the symptoms before operation were distinctly unfavorable. This case also was the only one in which there was an iridectomy. In the first case iridectomy was to have been a part of the operation, but hemorrhage ensued before that step was reached. In the last three cases the section was wholly in the cornea.

Preliminary iridectomy of the second eye has been more than once suggested as a measure of probable value when the first eye has been lost by hemorrhage, and cases have been reported in which such procedure has been successful. The following case shows that success may be obtained without preliminary iridectomy even when the general conditions are not favorable.

A woman of sixty-six was operated on by a colleague in the summer of 1896. Extraction was quickly fol-

lowed by hemorrhage, and the eye shrank. The gentleman who had operated asked me to operate on the other eye. The patient stated she was in fair health; but she appeared much older than her years, was rather feeble, very thin and much wrinkled. There was mature cataract; the pupil was fairly active; tension normal; projection somewhat doubtful. She was quite desirous to have the operation performed.

January 8, 1897. Simple extraction under cocaine. The pupil dilated rather slowly to admit the passage of a fairly good sized nucleus; a small amount of cortical was coaxed out. After extraction of the lens the eye seemed softer than usual. The iris returned to place readily. Eserine, one-tenth per cent. The bandage was maintained for four days. The pupil was small, round, central.

She returned home January 26th, sooner than I advised. The eye quiet, a little cortical in the upper part of the pupil. Vision .4.

A STUDY OF MEASUREMENTS IN CURVATURE OF THE SPINE.¹

BY G. W. FITZ, M.D.,

Assistant Professor of Physiology and Hygiene, and Medical Visitor, Harvard University.

DURING the past six years measurements and strength tests² have been made upon curvature cases in the Out-patient Department of the Boston Children's Hospital to determine the factors instrumental in the production of curvatures of the spine.

The strength tests taken are as follows: of the back, of the right and left side, and of the muscles moving the arms in the cardinal directions. The purpose was to measure the strength of the trunk muscles which had influence upon the postures of the spine, shoulders and arms, and to determine whether any unilateral weakness existed which could account for the curves. Cases in which the curvature was secondary to a paralysis have not been included in this study. In paralytic curvature there is weakness of the convex side, but in some paralytic cases there is marked asymmetry of strength without coincident curvature.

The back strength was taken with the back well bent and the legs straight by means of an ordinary dynamometer fastened to the floor. For the reason that varying age and gymnastic training produce great inequality in its value, it has not been included in this study: only those bilateral tests have been included which check each other regardless of the total strength of the individual.

The side strength was tested by the same dynamometer, and measured the ability of the individual to pull up with one hand, the body being bent side-wise and legs straight.

The tests named deltoid, scapular, latissimus dorsi and pectoral measured the pull made by the arms extended laterally at right angles to the body in the general direction of these muscles. In each case the feet were placed widely apart to give full support, and in most cases several tests were made and the maximum recorded. In order to get a satisfactory test of

the forward and back pull (pectoral and scapular) and to avoid the slipping of the feet upon the floor, it was found necessary for the operator to press upon the back of the shoulder for the pectoral test and upon the front for the scapular. This tended to localize the effort in the muscles immediately about the shoulder. Undoubtedly a better way to test the trunk muscles would be to fix the pelvis firmly and to allow the subject to make the effort unassisted; it was found difficult, however, to arrange the necessary apparatus and the other test was fairly satisfactory.

AVERAGE STRENGTH TESTS IN RELATION TO CHARACTER OF CURVE.

	Side.		Deltoid.		Scapular.		Lat. Dorsi.		Pectoral.	
	R.	L.	R.	L.	R.	L.	R.	L.	R.	L.
Rt. dorsal.	53.9	53.0	8.4	8.1	8.2	8.0	11.6	11.1	8.4	8.6
No. obs.	(22)	(22)	(41)	(41)	(40)	(40)	(41)	(41)	(41)	(41)
Left dorsal.	53.0	49.0	8.3	7.6	7.7	7.3	10.4	10.2	7.6	7.7
No. obs.	(12)	(12)	(21)	(21)	(21)	(21)	(21)	(21)	(21)	(21)
Rd. shoulders.	45.3	44.9	6.6	6.5	7.3	6.7	9.0	8.8	6.9	6.2
No. obs.	(13)	(13)	(33)	(33)	(33)	(33)	(33)	(33)	(33)	(33)
Miscellaneous.	55.7	51.3	7.4	7.4	7.1	6.5	9.4	9.1	7.3	7.1
No. obs.	(20)	(20)	(29)	(29)	(29)	(29)	(29)	(29)	(29)	(29)

It will be seen by reference to the table that the curvature cases are divided into two groups with right and left dorsal convexity respectively. A preliminary examination of the records failed to show evidence of consistent unilateral variation in strength. It was thought that a combination of all the observations would bring out in the averages any latent inequality of strength; therefore in the table are given the average lateral strengths for the number of observations indicated. These averages were obtained by adding together all the strength tests for each group of individuals and by dividing the resultant sums by the number in the group. A comparison of the numbers so obtained shows remarkable equality in strength between the two sides and suggests that there is no unilateral weakness to account for the curves. It will be noticed that there is a slight superiority of the right over the left in all the groups.

CONCLUSIONS.

(1) The cases of right dorsal curvature show no evidence of unilateral weakness.

(2) The cases of left dorsal curvature also show no evidence of unilateral weakness.

(3) The cases of round shoulders show similar equality between the strength of the two sides.

(4) The miscellaneous cases, including wry neck and other deformities, show bilateral equality in the strength of trunk muscles.

These cases of spinal curvature suggest that unilateral muscular weakness does not enter as an etiological factor in idiopathic curvature of the spine.

It may be added that in nearly all the cases of curvature studied a detailed history of deforming posture in sitting, standing, or more especially sleeping, was obtained, and seems to suggest an essential etiology of the trouble.

¹ Presented at the meeting of the American Orthopedic Association, Washington, D. C., May, 1897.

² These observations are reported through the courtesy of Dr. E. G. Brackett, who has charge of the Curvature Clinic.

THE PREVENTION OF PNEUMONIA FOLLOWING ANESTHESIA.¹

BY WM. F. WHITNEY, M.D., BOSTON.

OF late the attention of the profession has been called to the frequency of pneumonia after operations where anesthesia has been used. Whether it is really more common to-day than in the past is doubtful; but there are two factors which make it appear so. One is, that with the larger number of surgical cases a greater number of pneumonias may occur and yet the percentage remain the same. Another is, that with the perfection of asepsis, other infectious processes have been eliminated to such an extent that this one has an opportunity to develop unobscured, and thus has come into greater prominence.

Attempts have been made to prove that there is something peculiar to the pneumonia after ether, and directly attributable to that agent, and the name of ether-pneumonia has even been proposed. But the most careful observations have shown that the disease in the fatal cases differs in no way from the ordinary fibrinous form, and the cultures have shown it is caused by the same class of micro-organisms, at the head of which stand the pneumococcus.

While all the ways by which these bacteria can enter the system are not known and their introduction by means of the circulation cannot be denied, still, their direct route is through the air-passages, and this is a perfectly rational assumption of their mode of entrance.

In the distribution of these microbes, it has been found by Sternberg and others that they are present in the mouths of healthy individuals. It is probable in such cases that under ordinary circumstances the organism can render their action harmless. But there are exceptional conditions which render a person susceptible to pathogenic bacteria. As experimentation upon animals has shown prolonged and profound etherization is one of the conditions which increases this liability to infection for any of the septic ones. The patient, therefore, is in the most favorable condition for the development of the germs if they can find entrance, which is favored by the inhalation of mucus and saliva in the unconscious state.

While much cannot be done to prevent this increased susceptibility beyond as short and light etherization as possible, the thorough disinfection of the mouth before anesthesia is within the control of the surgeon, and should be as carefully attended to as the breast or leg that is to be amputated.

The details of this should be a thorough aseptic cleansing of the mouth, nose and pharynx at least twice, once in twelve hours and again immediately preceding anesthesia.

Each time the teeth should be brushed, then the mouth rinsed, especially about the roots of the teeth, and the throat gargled several times with a warm solution of chlorinated soda.

R	Lig. sodæ chlorinat.	3ij
	Aq. menth. piper.	3ij
	Glycerine	3ij

Afterwards the pharynx and tonsils sprayed with a solution of

R	Peroxide of hydrogen	1
	Aq.	3

Then the nose to be douched with a pint of a warm

saturated aqueous solution of boracic acid, to which a half a teaspoonful of salt has been added.

As a last detail, the cone or sponge used for the anesthetic should be sterilized for each case.

It may be urged that to carry out the above in every case would be exacting, and it would be very well to do it if it was certain that the organisms entered in no other way. Our knowledge, unfortunately, does not permit at present a selection of cases for which such a course should be reserved, and therefore every patient has the right to demand of the man in whose hands he so implicitly places his body and life that he should be given every chance for a rapid recovery. And he is entitled to the benefit of every detail, if it can be shown to be consistent with the line along which the science of surgery is advancing.

Clinical Department.

CLINICAL REPORT OF AN EPIDEMIC OF CEREBRO-SPINAL MENINGITIS.

BY FRANCIS H. WILLIAMS, M.D., BOSTON.

I DESIRE to outline briefly the experience we had at the Boston City Hospital with an epidemic of cerebro-spinal meningitis during last winter and spring.

The first case entered the hospital December 30, 1896, and nearly all the cases since then have been in the services of Drs. Withington and Bowditch and in my own. The records of the hospital from 1880 to December 30, 1896, include 39 cases, with a mortality of 59 per cent. From the latter date to June 1st there have been 47 cases,¹ 42 of which entered in March, April and May; that is to say, during the past five months there have been more patients with this disease in the hospital than in the previous seventeen years.

The tabulation of these 47 cases by localities, made by Dr. C. B. Dunlap, shows that one part of the city has not been more affected than another. The patients have been youths and adults, as the children have been sent to the Children's Hospital; and the form of the disease has been very severe. It has been characterized by sudden onset, with an average duration of about 13 days in the fatal cases, and the very high mortality in 47, the whole number of cases, of a little over 72 per cent.

The prominent symptoms have been intense headache, delirium, a stiffness of the muscles of the back of the neck, retraction and stupor; in some cases there have been diplopia, strabismus, deafness and vomiting; in 11 cases herpes labialis; in seven cases some form of eruption, but this does not justify the name of spotted fever, which is sometimes given to this disease. In 12 cases a blood-count was made, and in most of these there was leucocytosis. The serum test for typhoid fever was tried in eight cases, and found to be negative in all. Lumbar puncture was done in 32 cases; and judging from these this puncture does no harm, and it readily establishes the diagnosis when fluid containing pus and organisms is found. In the seven cases in which I performed the operation it yielded a positive result in all.

The operation, under strict antiseptic precautions, is

¹ Read before the Surgical Section of the Suffolk District Medical Society, April 7, 1897.

¹ To make this report more complete I have included the cases that entered during May.

readily done by using a small trocar to tap the sac surrounding the spinal cord, and draw off some of the fluid; the point of insertion is between the third and fourth lumbar vertebrae. I have usually chosen a point slightly lower than the lowest part of the spinous process of the second lumbar vertebra, and one inch outside of it, and inserted a small-sized trocar, somewhat downwards and inwards, to a depth of rather more than two inches. I have always used a trocar instead of a needle, as the latter is liable to be bent or broken off and is too small to allow the thick pus that is present in some cases to flow through it easily.

The lumbar puncture is very serviceable for diagnosis, as often there is no history and the symptoms may be few. It may also relieve pressure temporarily. That there is pressure is shown by the fact that the fluid is apt to squirt out at first with some force; and sometimes two ounces may be readily withdrawn. The diagnosis has been established in more than half of these 47 cases either by examination of the fluid obtained by lumbar puncture or by autopsy.

The present treatment of the disease is wholly unsatisfactory; but the fact that we have the means of making an early diagnosis in many cases, and that the organism is not a robust one and seems to be short-lived in the body, offers the hope that better treatment may soon be found.

A CASE OF DISLOCATION OF THE STERNUM: REDUCED.

BY J. S. STONE, M.D., AND F. J. COTTON, M.D., BOSTON.

E. B., age twenty-one, entered the accident-room at the Massachusetts General Hospital, May 19, 1896. He walked in, complaining of pain in the chest, of dyspnea, and inability to take a deep breath. He had fallen in the gymnasium in doing the "giant swing."

Examination showed a displacement of the gladiolus backward from the manubrium, with some overlapping. There was no other injury. Attempts at reduction by traction and extension from the head, while the patient coughed, were unsuccessful. He was then so placed that the angles of the scapulae rested on the end of the table, while an assistant lay across and fixed his legs and pelvis. The spine was then strongly extended by traction downward, applied to chin and occiput, and the arms were brought up and outward, the patient resisting the outward rotation. He was then directed to cough. At the first trial there was some slipping of the displaced bone; at the second, it jumped back into place. A plaster swathe was applied, and the patient was put to bed.

Next morning, after relief of slight dyspnea by slitting the swathe, the patient was discharged, with no symptoms other than slight soreness of the neck muscles.

Five days later he reported, anxious to resume training. In a letter written nearly three years after the injury, he writes that he resumed gymnastic work even before he reported at the hospital; and that neither then nor since did he suffer any inconvenience from the injury.

The mechanism of the injury is unusual and interesting. The patient stated that the bone (the gladiolus) was driven in by his chin, the brunt of the fall being received on the head and the back of the neck. In the ordinary individual the flexed chin does not

nearly reach the gladiolus; but this patient, a tall, big-boned athlete, had a long neck and an unusually long heavy jaw, and evidently flexion was carried beyond any usual limit by the rotation of the body about the head as a fixed point.

The outward rotation of the arms, acting through the tense pectorals, was tried, with the idea that this might give a more direct traction on the upper rib insertions of the muscle, and so, indirectly, on the manubrium. It certainly was of help in making extension; but, as the previous trials (where this scheme was not tried) were made with less rigid fixation of the trunk, no positive statement can be made as to the value of the innovation.

Medical Progress.

RECENT PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

(Concluded from No. 8, p. 181.)

THE TREATMENT OF ARTIFICIAL ANUS BY PRIMARY INCISION INTO THE PERITONEAL CAVITY.

IN the treatment of artificial anus by operative procedure great difficulty is encountered in preserving aseptic conditions in the peritoneal cavity and gaining a knowledge of the exact position and the amount of adhesions which bind the intestines together.

To overcome these difficulties Gangolphe²⁵ advises the following method of operating. The abdominal parietes surrounding the artificial anus are incised down to the peritoneum, isolating the anus and surrounding area. The incision embraces the skin and subcutaneous tissues solely. At the upper angle of the incision the cut is deepened so that it includes the peritoneum and admits the passage of the exploratory finger within the abdominal cavity. After a careful examination of the conditions present, curved scissors are passed along the finger and the entire incision is completed. The anus thus freed is drawn outside, surrounded by aseptic pads, and the intestine united by the most suitable method of enterorrhaphy. The intestine is then returned to the abdominal cavity and the parietes closed by a suitable method of suture, as in laparotomy.

The author claims the following advantages for this method:

(1) It is rapid. The surgeon is in no danger of wounding any portion of the intestines, and can go immediately into the peritoneal cavity.

(2) It is sure. The finger introduced in the cavity explores beforehand, and then guides the scissors, which cut free the artificial anus without endangering the remaining intestines.

(3) It permits of the drawing out of the entire mass upon sterilized compresses, where the principal part of the operation can be done leisurely and with easy access. This insures asepsis and diminishes the chance of infection.

(4) It is applicable in all cases, and produces success in cases that were formerly unsuccessful.

SUBPHRENIC ABSCESS AND ITS TREATMENT.

Dr. Lauenstein of Hamburg, in an article on this subject, states that he has had six cases of subphrenic

²⁵ Rev. de Chir., April, 1896; American Journal of Medical Sciences, December, 1896, p. 719.

abscess, and says that as to the etiology, they might arise from (1) the stomach and duodenum; (2) the vermiform appendix; (3) the bile-ducts and liver; (4) the kidney; (5) hydatids; (6) they might be metastatic; (7) they might come from the thorax; or (8) from the ribs. Occasionally they get well spontaneously by rupturing into a hollow viscus; but out of 104 cases treated expectantly only 6 lived, while of 74 cases treated surgically 39 recovered.

SURGERY OF THE PANCREAS.

Bottini (Cagliari)²⁶ summarizes an article written by him on this subject as follows:

(1) Operations on the head of the pancreas are possible if one of the two excretory ducts are left intact.

(2) Small wounds in the ductus choledochus can heal without closing the lumen of the duct.

(3) After removal of the entire head of the pancreas the flow of pancreatic secretion into the intestine cannot be restored by any known means, and death results.

(4) The pancreatic fluid may indirectly cause peritonitis if it comes in contact with the peritoneum. Hence wounds of the pancreas should be well closed or treated extra-peritoneally.

(5) Complete extirpation of the pancreas is fatal either from infection, lesion of nerve plexi, intestinal necrosis or by elimination of its function.

(6) Solid benign tumors of the head, if not too extensive, can be removed with a fair chance of success. Also with cysts, hemorrhages, abscesses, fat necrosis, primary tuberculosis, calculus and "annular" pancreas, the same is true of the results from operation.

PERINEAL PROSTATECTOMY.

Neinhaus²⁷ reports the results of 11 cases from Socin's Clinic at Basel. Socin uses the transverse curved incision of Kocher, that begins at the ischial tuberosity on one side, extends forward across the perineum in a curved line to the bulb of the urethra, and then backward and outward to the tuberosity of the opposite side. Through this incision the whole prostate is exposed, and the urethra and rectum can be well retracted.

No patient died from the operation. Spontaneous nutrition returned in all, and continued in all but one. Six cases were cured. Five had permanent fistulae due to accidental injury of the urethra or rectum.

The operation is indicated where there is retention of urine from general enlargement of one or both prostatic lobes. The enlarged or pedunculated middle lobe can be best treated by suprapubic cystotomy. The operation should be done before the mucous membrane of the bladder is extensively affected by catarrhal inflammation or before the tonicity is entirely lost. In the latter case the bladder is unable to expel the urine after the obstruction is removed.

PATHOLOGY AND TREATMENT OF CHILBLAINS.

Wright²⁸ has investigated the condition of blood-coagulability in ten cases of chilblains. Two of these cases were cases of aggravated chilblains occurring in adult males. The blood-coagulation occurred in these

patients in respectively nine minutes and nine and a quarter minutes. Four of these cases were cases of aggravated chilblains occurring in adult females. The blood-coagulation occupied respectively thirteen minutes, eleven minutes, eight and three-quarter minutes, and seven and a half minutes. Lastly, four of these ten cases were mild cases of chilblains occurring in schoolboys. The coagulation of these cases occupied respectively eleven minutes, nine and a quarter minutes, seven and three-quarters minutes, and four and a half minutes. It is obvious, therefore, when we consider that the normal blood coagulation takes place in three or four minutes, that all these cases of chilblains, with the exception of the last case, were associated with a very notable defect of blood-coagulability.

In view of the etiological facts which are thus disclosed, the obvious indication for treatment in a case of chilblains is to take steps to augment the patient's blood-coagulability. In conformity with these indications the author placed his patients upon a regimen of calcium chloride (after duly cautioning them against lowering their blood-coagulability by the ingestion of sour fruits, alcohol, or excessive quantities of fluids).

EXTIRPATION OF THE ASCENDING VENA CAVA.

Marconi's²⁹ (Pavia) reports a case of removal of a portion of the vena cava with a large pre-vertebral lympho-sarcoma, with success; and which he claims to have demonstrated at autopsy, three years later, his patient having died from pulmonary tuberculosis. He found a defect of the vena cava of four to five centimetres a short distance above the junction of the iliac veins. Collateral circulation was through the ovarian, supra-renal, small phrenic, small azygos, and renal veins. The explanation of the result is that the tumor had gradually closed the vena cava, and that collateral circulation existed at the time of the operation, which simply removed an already obliterated vein.

THE THERAPEUTIC VALUE OF THE MIXED TOXINS OF THE STREPTOCOCCUS OF ERYSIPELAS AND BACILLUS PRODIGIOSUS IN THE TREATMENT OF INOPERABLE MALIGNANT TUMORS.

Wm. B. Coley³⁰ draws the following conclusions from a careful study of a series of cases:

(1) The mixed toxins of erysipelas and bacillus prodigiosus exercise an antagonistic and specific influence upon malignant tumors, which influence in a certain proportion of cases may be curative.

(2) This influence is slight in most cases of carcinoma (including epithelioma); most marked in sarcoma; but varies with the different types, the spindle-celled form showing by far the greatest influence.

(3) The action of the toxins is not merely local in character, but systemic.

(4) The toxins should be used only in clearly inoperable cases, or after primary operation to prevent recurrence.

(5) The results will vary greatly with the strength of the preparation, the most virulent cultures giving the best results.

CONCERNING THE BASIS AND RESULTS OF BACTERIAL THERAPEUTICS OF MALIGNANT TUMORS.

Petersen³¹ has made a thorough and careful inves-

³⁰ American Journal of Medical Sciences, September, 1896, p. 251.

³¹ Beiträge zur klin. Chir., Bd. xvii, Heft 2.

gation of this method of treatment. His conclusions he formulates as follows:

(1) With carcinoma all methods to date have failed.

(2) With sarcoma only in (quite) exceptional cases is a successful result to be expected. The reasons of these exceptions are unknown, and future efforts are confined to inoperable cases and for prophylaxis after operations.

(3) The result is in general proportionate to the amount of the general reaction and also to its degree of effectiveness: Inoculation of a virulent streptococcus, the sterilized mixed and prodigious *sterile* culture, streptococcus filtrate and carcinoma serum. The action of the sterilized mixed culture (*Mischkultur sterilisat*) depends mostly on the prodigious toxins. The cancer serum corresponds in its characteristics and action to a diluted streptococcus filtrate.

(4) The action of the toxin corresponds to the general reaction (especially the fever) and the local reaction of the tumor (parenchymatous inflammation).

(5) The questionable advantages of the treatment are counterbalanced by the danger of toxin poisoning and a stimulation of the tumor growth.

AMPUTATION AT THE HIP-JOINT.

Wyeth³² reports 69 cases of amputation at the hip-joint by his method; 11 patients died, a death-rate of 15.9 per cent.

His method, which is also applicable to the shoulder-joint, is as follows: The patient should be placed with the sacrum resting upon the corner of the operating-table, the sound limb and arms being wrapped with cotton-batting and thoroughly protected from unnecessary loss of heat. The limb to be amputated should be emptied of blood by elevation of the foot, and by the application of the Esmarch bandage, commencing at the toes. Under certain conditions, the bandage can be only partially applied. When a tumor exists, or when septic infiltration is present, pressure should be exercised only to within five inches of the diseased portion for fear of driving the septic material into the vessels. After injuries with great destruction, crushing or pulpefaction, one must generally trust to elevation, as the Esmarch bandage cannot always be applied. While the member is elevated, and before the Esmarch bandage is removed, the rubber tubing constrictor is applied. The object of this constriction is the occlusion of every vessel above the level of the hip-joint, permitting the disarticulation to be completed and the vessels secured without hemorrhage and before the tourniquet is removed. To prevent any possibility of the tourniquet slipping, I employ two large steel needles or skewers, three-sixteenths of an inch in diameter and ten inches long, one of which is introduced one-fourth of an inch below the anterior superior spine of the ilium and slightly to the inner side of this prominence, and is made to traverse superficially for about three inches the muscles and fascia on the outer side of the hip, emerging on a level with the point of entrance. The point of the second needle is thrust through the skin and tendon of the origin of the adductor longus muscle, half an inch below the crotch, the point emerging an inch below the tuber ischii. The points should be shielded at once with cork to prevent injury to the hands of the operator. No ves-

sels are endangered by these skewers. A mat or compress of sterile gauze, about two inches thick and four inches square, is laid over the femoral artery and vein as they cross the brim of the pelvis; over this a piece of strong, white rubber tubing, half an inch in diameter when unstretched, and long enough when in position to go five or six times around the thigh, is now wound very tightly around and above the fixation needles and tied. If the Esmarch bandage has been employed, it is now removed. Excepting the small quantity of blood between the limit of the Esmarch bandage and the constricting tube, the extremity is bloodless, and will remain so.

The author has reported his cases in detail.

THE SUTURING OF ARTERIAL WOUNDS.

Glück reported to the Berlin Medical Society, in July, 1895, the suturing of an arterial wall in an arterio-venous aneurism. Heidenhain³³ reports a case in which, during the removal of a carcinoma of the breast, the axillary artery was wounded. The edges of the wound were caught with hemostatic forceps, and a continuous suture of catgut introduced with needles, such as are used in inserting intestinal sutures. The wound was packed and not closed until the end of forty-eight hours, when all danger of secondary hemorrhage seemed to be past. The case recovered completely, and there was no evidence of traumatic aneurism when the author examined the patient six months later. The author advises the use of catgut, such as is used for ligatures, and the union of endothelium to endothelium; sometimes there is a slight oozing through the stitch-wounds after the suture is completed, but packing for a few minutes will stop it. He does not believe it is necessary to heal the wound by secondary suture, as the healing of the tissues about the artery tends to support it.

THE TREATMENT OF FRACTURE OF THE PATELLA WITH CONTINUOUS EXTENSION AND WITHOUT CONFINEMENT TO BED.

Bryant³⁴ describes the following method of treating recent fractures of the patella, which he has found satisfactory in 13 cases. The plan is presented, the author says, not as a substitute for operative measures, but as an adjunct to them, as the patient can with this appliance be about without special danger or discomfort after wiring, etc.

A plaster-of-Paris cast is applied to the leg, beginning at the bases of the toes and extending up to and partly embracing the lower fragment of the patella, and allowed to dry. An ordinary Buck's extension is next applied to the thigh. The adhesive plaster extends from the perineum to the upper border of the upper fragment and terminates in a loop at either side of the limb a little below the knee. After the plaster has become firmly adherent gentle traction is made by attaching elastic cords, which pass under the sole of the foot to the loops on either side of the knee, and a plaster-of-Paris cast is applied to the thigh, reaching from the upper limit of the adhesive plaster down to the upper fragment, where the plaster is so fashioned and padded as to hold it as nearly as possible in contact with its fellow. A posterior support or splint is then applied and secured with a plaster-of-Paris ban-

³² Centrallblatt f. Chir., 1895, No. 49; American Journal of Medical Sciences, December, 1896, p. 719.

³⁴ Medical Record, 1896, vol. xlix, No. 14; American Journal of Medical Sciences, July, 1896, p. 99.

dage. The final step consists in drawing together the fragments of the patella as firmly as possible, either with adhesive strips obliquely applied or by means of a knee-cap suitably constructed.

After the apparatus is comfortably in position the patient is permitted to walk about with the aid of crutches, the limb being kept in an advanced position however, by a sling carried beneath the sole of the foot and around the neck of the patient.

DOUBLE-POINTED TACKS FOR SUTURES.

A novel substitute for a suture in skin incisions is recommended by Wachsmann in the *Berl. klin. Woch.*, November 9, 1896.⁸⁵ It is neither more nor less than a double-pointed tack, such as is used to nail matting to the floor. The points are made short, about one-quarter inch long, and are slightly bent toward the centre so as to prevent their slipping out. It is claimed that they can be applied in about one-quarter of the time required for a suture. They are made of fine steel wire and nickel-plated. They can be sterilized in any manner, and may be left in the skin ten days if necessary without setting up any irritation.

CELLULOID BANDAGES.

Landerer and Kirsch,⁸⁶ have experimented with celluloid as a substitute for plaster-of-Paris in bandages. The weight of such a bandage is less than one-fourth that of a plaster-of-Paris one and less than half that of one stiffened with water-glass. It is said to be not very expensive. According to the authors, a jacket costs in Germany about five marks (\$1.25), which is no real objection to its use when one considers that, if well made, it will last for months, and presents the further advantage of a smooth surface, readily cleaned, and is impervious to urine and other discharges.

Its application is as follows:

The sheet celluloid is cut into small pieces and dissolved in a close-stoppered bottle in acetone, enough of the fluid being used to rise four times as high in the bottle as the celluloid. This solution of celluloid is rubbed into each layer of the gauze or crinolin bandage or jacket, an ordinary kid glove being worn for the purpose, as the celluloid otherwise dries on the skin, and can only be washed off by acetone. For a jacket at least ten layers are necessary; for a bandage from four to six layers, according to the strength required. The outer layer is smeared with a coating of the celluloid, which forms, when dry, a highly polished surface. It takes three or four hours for a celluloid bandage to dry. That is considerably longer than is the case if plaster-of-Paris is used. In order to permit of ventilation, small holes may be punctured in the jacket wherever necessary.

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

PAUL THORNDIKE, M.D., SECRETARY.

REGULAR Meeting, Wednesday, April 7, 1897, Dr. H. L. BURRELL in the chair.

Dr. A. T. CABOT read a paper entitled,

OBSERVATIONS UPON THE RECURRENCE OF STONE IN THE BLADDER.

Dr. MALLORY presented a specimen from

A CASE OF RUPTURED AORTA.

He said: I was called to make the autopsy in this case about a year ago. A man with his wife and child were driving through a neighboring town in a buggy on a dark night. The road was in very bad condition. One of the wheels went into a deep rut; the woman was thrown out, and the child, which she had been carrying in her lap, fell with her, she holding him in her arms, and struck her on the breast. Her condition was very serious. It was two or three days before they could get her to her home. A physician there attended her. At the end of two weeks she was up and around, although she had considerable pain; but as she was attending to her work, he told her at the end of that time he thought there was no need of his coming to see her any more. Two weeks later, after breakfast, when she was up and dressed, she suddenly died, and I was called to do the autopsy.

The woman was of medium size and well-built. From the left chest, when I opened the thorax, serous fluid flowed out, and beneath that was a large amount of clotted blood, the whole amount weighing three pounds and twelve ounces. The left lung was shoved up to the upper part of the thorax, the apex was quite firmly adherent by old fibrous adhesions. Just at the top of the adhesions there was a rent where I could get in a couple of fingers. The pericardium was normal. The thoracic organs were taken out in one piece so as to examine the heart and blood-vessels in continuity. On slitting up the aorta a rupture was found just at the beginning of the descending portion of the arch—a spiral rupture, running a little more than once around the aorta. The rupture in the aorta was quite sharp, the edges three centimetres apart. It opened into a very irregular sac about the size of a hen's egg. Apparently all the coats of the aorta had been ruptured. The base of this sac was formed in part by the apex of the lung and by the adhesions which bound the lung to the vertebræ at the upper part of the thorax. The blood had also worked its way down between the coats of the aorta, dissecting off the media from the adventitia, and there was clotted blood below the diaphragm—in other words, a dissecting aneurism had formed there. It would seem that, as a result of the increased blood-pressure due to the child striking the woman on the chest, there had been a rupture of the aorta; following that had come an aneurism which would probably have burst at once into the pleural cavity if it had not been for these old fibrous adhesions. At the end of four weeks the aneurism had dissected its way through these adhesions, and finally the blood poured into the pleural cavity. The specimen does not show very well unless you take it in your hands and draw the vessel apart. The

⁸⁵ *Medical News*, January 9, 1897, p. 52.

⁸⁶ *Centralblatt f. Chir.*, 1896, No. 29; *Medical News*, September 26, 1896, p. 354.

cusps of the aortic valve are, at this point, here the ascending portion of the arch, and here the upper portion of the thoracic aorta. The rupture occurred at this point. You will notice a certain amount of arterio-sclerosis. The woman was forty-two years old, and had slight general arterio-sclerosis and arterio-sclerotic kidneys. Still without the great pressure due to the blow, she undoubtedly would have lived many years so far as the blood-vessels are concerned.

In rupture of the aorta, in the majority of cases, there is some lesion of the intima, but it is not necessary. Cases have been known where the violence of the blow was comparatively slight. In one case, in the Warren Museum, a young man fell twenty feet and ruptured his aorta, which was practically normal. Quite a rupture shows at this point. Another case is even more interesting. The autopsy was done by Dr. Fitz. A woman of about sixty was found dead in the water-closet. Examination showed a rupture of the aorta, with a dissecting aneurism secondary to that, and then rupture of this aneurism into one of the cavities. It would seem that the cause of the rupture had been the straining at stool. In this case the aorta is otherwise in very good condition.

DR. GOLDTHWAIT: The length of time the patient lived is rather interesting compared with Dr. Bradford's case of dissecting aneurism of the common iliac. This patient was about several days after the first pain in the side. At the time of admission to the hospital there was simply a fulness in the iliac fossa, which was supposed to be inflammation of the appendix. The dissection after death showed that the two inner coats of the artery had ruptured, and that the outer coat had contained the blood until the time for operation. The swelling was fusiform and two or three inches across.

DR. W. F. WHITNEY exhibited a series of

SPECIMENS PRESERVED WITH THEIR NATURAL
COLORS BY KAISERLING'S METHOD.

DR. BURRELL: Do I understand this hardens the specimen?

DR. WHITNEY: The formaline used at first hardens it. I cannot say what it hardens exactly. It hardens in a somewhat different way from alcohol. It seems to preserve more of the tissues, to harden more regularly. There is not so much distortion of the tissues with formaline. Perhaps Dr. Cabot remembers a little tumor he took out in the popliteal space without cutting it. I hardened that for him; and on taking it out and cutting it, it turns out to be a little hematoma. It preserves the shape perfectly.

DR. WHITNEY read a paper on

THE PREVENTION OF PNEUMONIA AFTER ANESTHESIA.¹

DR. ENGELMANN: Can Dr. Whitney tell us the percentage of such pneumonias and their mortality?

DR. WHITNEY: I cannot. I only know that it is a not infrequent thing to hear of pneumonias following operation. I won't say that it is any more fatal than other pneumonia, because it is the same.

DR. ENGELMANN: It is not a question of the mortality alone, but of the frequency as well, of pneumonia after ether anesthesia, which has proved a most annoying and serious complication to operators on the other side of the Atlantic. Dr. Whitney's paper is most opportune, as placing the question squarely before us;

and I trust that it may serve to bring out the facts in the case as here observed, where ether has been so constantly employed to the exclusion practically of other anesthetics.

Recent English and German reports show a mortality and a frequency of pneumonia, following the administration of ether, here entirely unknown or unnoted. Whatever the cause, these results observed by capable and experienced surgeons demand our consideration. In fact, if we include these cases, as we should, the death-rate from ether is greater than that from chloroform, and the latter is decidedly the safer anesthetic.

Most startling are the observations made at the clinic in Erlangen from 1887 to 1894. In the 338 narcoses ether was employed 38 times, with 6 pneumonias, 4 fatal; chloroform in 300 cases, with 15 pneumonias, of which 4 were fatal.

Gurlt, who has made a compilation at the request of the German Surgical Congress, to determine the relative safety of anesthetics, finds, in his 52,677 cases, the mortality of ether to be 1 to 6,004; of chloroform, 1 to 2,909. He reports 30 cases of post-anesthetic pneumonia, with 15 deaths, 13 of these after abdominal operation.²

Poppert³ presents eight deaths from broncho-pneumonia after ether, and one from edema of the lungs; which alone, if added to Gurlt's statistics, increase the mortality from ether far above that from chloroform, fully double—ether deaths 1 to 1,167, chloroform 1 to 2,645 (1894).

These are data affecting the harmlessness of ether, and all lung complications are included. A distinction is not always made between true pneumonia, bronchitis and broncho-pneumonia or inhalation pneumonia, *schluck pneumonie* of the Germans. The secretions of the mouth and nose, or the stomach contents when vomiting occurs, pass into the trachea and lungs; to this the patient is far more exposed than in chloroform anesthesia. The danger seems to lie in the hypersecretion, the increased flow of mucus and saliva from ether more than from chloroform; then the direct ether vapor, in much greater quantities than chloroform, rapidly causes anesthesia of velum, palate and base of tongue, and opens the way for fluids to the air-passages. The secretions entering the bronchi lead, as a mechanical irritant, to bronchitis or broncho-pneumonia, and as a carrier of infection to true lobar pneumonia; this, as in past broncho-pneumonia, when it occurs, is due to auto-infection, to the entrance of the streptococcus, which, like the pneumococcus and staphylococcus frequently dormant in the mouth and nares, is carried down by the secretions to more fertile soil. What influence the chilling of the pulmonary tissues by the rapid evaporation of ether, as suggested by Tait, may exert, I am unable to say. In some cases the quality of the anesthetic is at fault, as an impure or carelessly kept ether will invariably irritate the air-passages.

It is evident that these complications occur more frequently in the practice of surgeons more habituated to the use of chloroform; but the danger does exist, and must be met and guarded against. It is sufficient to warrant a most thorough investigation and a review of records of the great hospital of this city where ether anesthesia has received so much attention.

Unless more favorable results can be shown it must

¹ See page 311 of the Journal.

² Annals of Surgery, February, 1896.

³ Deutsche Med. Woch., September 13, 1894.

appear that the harmlessness of ether anesthesia is not what it has been claimed to be; while safer than chloroform during the narcosis, pulmonary sequences would mark ether as the more dangerous of the two anesthetics.

DR. CABOT: I think this field opened for our consideration is very interesting and very important, and one which I shall certainly look into. I think, however, of the cases I have seen where pneumonias have followed etherization, the pneumonia has apparently followed a bronchitis which usually existed to a slight degree before the operation. I think I have seen several of those cases. A man left the hospital to-day who gave me quite a lot of trouble after a hernia operation from fever accompanied by bronchitis. I could not get the medical men to confess to any pneumonia, although my house pupil thought he found a little lack of resonance at one part of the lung; but I have an impression got from an experience last year that different ethers may act differently in the matter of producing pneumonia. I had a case of pneumonia last year, one of the first for a long time after anesthesia, at least which I think could be traced to anesthesia, and at the same time the other surgeons were having somewhat the same experience. Dr. Elliot had two or three cases, and Dr. Richardson had some; they were my colleagues at the time. I changed the ether, and had no more trouble. I happened to have no more trouble that year. I won't say it was cause and effect. I think some of the other gentlemen who did not change did have more trouble. I think a more irritating ether may act simply by its irritation in preparing a soil for bacterial growth in the lung. Bacteria, I fancy, get to the lung pretty readily. I think the result depends on whether the lungs are properly resistant to them or are irritated so that they become non-resistant. I do not know how much there is in that idea, but it is the one I have hitherto held in regard to these cases.

I should say that pneumonia occurs very rarely after etherization. I do not remember more than two or three cases in an experience of twenty years; but, as Dr. Whitney said, one may be deceived by thinking that the pneumonia is some septic process, and accounting for the symptoms in that way.

DR. PRESCOTT: It seems to me a pneumonia due to the pneumococcus after an etherization must be quite rare, because in looking up the subject some time ago I could find few cases. Recently there has been a case at the City Hospital of which I cannot speak in detail, but some of the facts follow. The patient was admitted about the 16th of last February, and a few days later was examined under ether, no operation being performed. That afternoon she began to have pain in the side; and the next night temperature was 103° and she had an acute pneumonia. This would seem to be a case where the exciting cause, at least, was the etherization, as no operation was done but simply a vaginal examination made.

It is strange that all the cases where there has been any probability that there was a pneumonia following etherization have been those cases where the gynecologist has made an examination or where some operation has been done upon the pelvis. There was a case at the Carney Hospital (which was the cause of my looking up the subject) where the woman was examined for the question of operation for fibroid. After forty-eight hours she developed pneumonia;

within a few hours she was delivered of a good-sized baby, and shortly after she died. Dr. E. W. Cushing had a case where, after etherization for some pelvic operation, there was a pneumonia started up; but in this case there was a distinct history of exposure before the operation. There are one or two cases in literature reported by gynecologists. The case at the Massachusetts Hospital was a case which occurred after etherization for an operation for restoring a perineum. Although that case was not typical of frank pneumonia, still it was probably a pneumonia following etherization, whether it was due to that or not. It seems to me a good many of the cases have come on pretty quickly to be due to the etherization; still some of the men with whom I have talked have thought the sooner it came on after the etherization the more likely it was to be due to the irritation caused by the ether. It hardly seems possible that an irritation caused by ether after a short vaginal examination, as in the case at the City Hospital last February, could cause a pneumonia to start up within forty-eight hours that would send the temperature up to 103° . I can see no objection to the sterilizing method before etherization; but whether the cases of pneumonia after etherization are common enough to warrant so much trouble I am not prepared to say, but I should not think they were.

Dr. Munro asks me how many cases there have been at the City Hospital. I found none at the time I made the investigation. I think the period extended over ten years. I looked over all the autopsies at that time, and there were no cases that came to autopsy where the pneumonia followed etherization since the hospital started. I looked up the records of all the pneumonia cases that came to autopsy. I looked over the records at the Carney, the City and the Massachusetts General Hospitals for a number of years (during which time I estimated there must have been 100,000 etherizations), and found one case at the Carney, one at the Massachusetts General, of which I have spoken. Dr. Post said he had had a case at the City; but he could not find it, and I could not find it. Those three cases were the only cases I could find in the records of those hospitals. There was a case at the Free Hospital for Women, that Dr. Davenport had, but the records were not such as to warrant any conclusion as to its being a pneumonia. A woman was curetted, and within a few days the temperature went to 105° . Dr. Davenport told me he thought it was pneumonia. Dr. Watson told me he had a number of cases of pneumonia after etherization, and he kindly looked them up for me; but all of them were in men rather beyond middle life, and where it was more an inhalation or broncho-pneumonia than a lobar pneumonia. In my investigation I only took lobar pneumonia. When Dr. Watson looked his cases up, he could find no cases of lobar pneumonia. I asked a good many men in private practice, and they could not remember any cases; so that the only cases I could find in Boston were five where it was probable or possible.

DR. WHITNEY: Dr. Prescott says he examined 100,000 etherizations, and found only five cases of pneumonia. I know of two cases at the Massachusetts Hospital this last winter.

DR. MALLORY: It seems to me it would be very wrong to consider only frank pneumonias. If you are going to sterilize the mouth, it would be more advisable to sterilize with reference to broncho-pneumonia,

which kills just as well as frank pneumonia and much more frequently in these cases.

DR. PRESCOTT: I agree perfectly that there is much more danger from inhalation pneumonia than from lobar pneumonia after etherization.

DR. MUNRO: Every surgeon can recall cases where the patient having been prepared for operation and operation refused, the patient came down within twenty-four or forty-eight hours with frank pneumonia. I think this is a factor that ought to be considered.

DR. MUMFORD: Too much pains cannot be taken in preparing a patient for an ether operation; that almost goes without saying. Anything which may contribute to a patient's comfort and safety should be tried. Care of the nose, naso-pharynx, mouth and fauces is a rational measure. Though it is obvious that the disinfection of these parts cannot be complete, even the partial removal of colonies of bacteria must be of value; and most disinfection is partial, at the best.

One important factor in etherization, and a factor too often lost sight of, is the etherizer. Few men know how to give ether properly. I have not always seen it well done — seldom by the younger hospital house-officers, nor always by practising physicians. Etherizers are either over-bold or over-timid. The patient is drenched with ether; he is brought rapidly and through an agony of suffocating struggles to the danger-point, where he remains choked up with bacteria-laden mucus, which works its way slowly into the trachea and bronchi, or else he is under-etherized and goes through the operation in a state of vomiting and partial asphyxia.

I must admit that as my knowledge of ether broadens, I am growing less confident of its harmlessness in unskilled hands; and I do not doubt that unfamiliarity with its proper use, as admitted by the gentleman from St. Louis and other chloroform advocates, has led to a misconception of its range of value. When good ether is properly given, I believe that inhalation of bacteria-laden mucus never occurs. It is when improperly given that pulmonary disturbances follow.

DR. ENGLEMAN: I would ask Dr. Whitney whether he has not noted pneumonia from ether more frequently after abdominal operation than after any other surgical interference. This I believe to be the case, and so it would appear from the observations of Gurlt, who found that 13 of the 30 post-anesthetic pneumonias he has collected have followed abdominal operations. I emphasize the fact more especially in response to the remark of Dr. Prescott on ether pneumonia in the practice of gynecologists, which needs explanation. He, no doubt, had abdominal operations in mind; as I myself have almost constantly used chloroform, my experience with ether, though most satisfactory, is too limited to warrant deductions. I am convinced that gynecologists present accustomed to the use of ether will bear me out in the statement that post-operative pneumonias result after abdominal rather than vaginal operations; and this seems plausible, as the accumulated secretions are not so readily expelled on account of the abdominal pain in coughing, — the patient dreads the suffering and controls the cough, to her serious injury. Then, also, in this class of cases, she is generally exposed for a longer time to the action of the anesthetic.

DR. WHITNEY: Of course, as I stated in the paper,

it is one of those things it will be almost impossible to prove absolutely; yet if one has the conviction that this is a source of danger, it seems to me an attempt should be made to render the parts as clean as possible. As regards laparotomy, I have no statistics to offer. If it is a fact, the explanation of it is perhaps that abdominal operations are of considerable length, under somewhat depressing influences, attended with more or less loss of heat, and that these factors may in some way add to the liability of infection. My purpose in bringing the subject before the Society was to turn the attention of the profession to it; and if it is their conviction that stricter asepsis should be carried out in this direction, I shall feel I have accomplished all I intended to by bringing this subject up.

DR. BURRELL: There are several points that have been brought out by this paper and the discussion that has ensued that are of peculiar interest. In the first place, as to the number of cases of pneumonia that have occurred after etherization, I think we all agree that when a man with Dr. Cabot's experience says he has seen but very few cases of pneumonia following etherization, it is a statement which commands our attention. If an occasional case of "frank" pneumonia in contradistinction from inhalation pneumonia occurs, it seems to me far more logical to infer that it is due to the improper administration of ether than to the inhalation of the pneumococcus. It is very true that the fact of the inhalation of ether may have lowered the vitality of the patient to a point where he is susceptible to the pneumococcus, yet the improper administration of ether, I regret to say, is very common. I constantly see patients drenched with ether, and the vitality of such patients must be lowered. To me it has often seemed strange that patients do not die more frequently from the abuse of ether. If one is to disinfect the nares, mouth and pharynx, and rid those parts of germs, is it not probable that these same germs exist lower down in the respiratory tract? I feel sure that we all appreciate Dr. Whitney's paper, and for one I wish to thank him for having brought this subject to our attention. The frequency with which ether is given makes the subject of etherization of such importance that any light that can be shed upon it is of value.

DR. WHITNEY: I don't think the pneumococcus has been found below the pharynx in health, but that I cannot say positively.

DRAWING OF THE KNEE-JOINT.

DR. J. E. GOLDTHWAIT: Here is a drawing showing the knee-joint of a leg amputated in the dissecting-room. The case shows beautifully the focus of disease in the head of the tibia; shows the patella adherent at the head of the femur; and shows in an interesting way the amount of fibrous tissue between the femur and tibia, which explains the fact that the patella is so frequently adherent and yet the tibia can be moved back and forth.

ACTIONABLE WORDS. — To render words spoken of and concerning a physician actionable, the supreme court of Indiana states, in the case of *Divens vs. Meredith*, they must be spoken of him in his professional character. It is not enough that the language disparages him generally, or that his general reputation is thereby affected, or that the words used tend to injure him in his profession.

AMERICAN NEUROLOGICAL ASSOCIATION.

TWENTY-THIRD ANNUAL MEETING, WASHINGTON, D. C.,
MAY 4, 5 AND 6, 1897.

FIRST DAY. — TUESDAY.

DR. M. ALLEN STARR, of New York, delivered the
PRESIDENT'S ADDRESS.

He referred to the transmission of sensory impulses through the spinal cord, and thought that the conclusions derived from physiological experiments upon the lower animals were open to grave criticism: first, because of the fact that the majority of such experiments performed years ago were done without antiseptic precautions and were attended by secondary septic inflammations of the cord and its meninges, which invalidated the conclusions drawn from them; and, secondly, because of the great variation in the anatomical structure of the cords of the lower animals and of man. While investigations have abundantly confirmed the general results long known as ascending degeneration in the spinal cord, after lesions of the nerve roots and after lesions of a transverse nature, the recent methods of investigation, especially the staining methods of Weigert, Van Gieson and Marchi, have furnished some interesting results.

It is no longer possible to speak of the columns of the cord as being exclusively ascending or descending in the direction of their fibres. Recent investigations by Hoche have shown the existence of many association fibres of limited extent in the direct cerebellar columns and in the columns of Gowers; and therefore it seems evident that every column of the cord contains fibres which pass in both directions. It is thus proven that the number of the short tracts in the cord is far greater than the number of long tracts; and inasmuch as these short tracts can only be nerve roots, or else tracts of association, it is evident that there are but few very long fibres extending through the cord to the brain. Many of these long fibres supposed to reach the brain really terminate in the spinal cord itself. There is no tract passing directly from the cord to the brain cortex. Even if the lemniscus is continuous from the medulla to the cortex, it cannot be stated that the lemniscus forms a direct sensory tract from the cord to the brain, since it begins in the nuclei gracilis and cuneatus of the medulla. A sensory impression of sufficient severity, or if continuous, may practically throw into activity almost the entire subcortical nervous system. It therefore seems quite evident that the transmission of sensations through the cord must have for an anatomical basis a series of short neurons, each conveying the impulse from the level of its reception in the cord to a level somewhat higher, where again it is transferred to any other neuron; and so on, till it reaches the cortex.

Is it not therefore evident that in the transmission of sensations through the spinal cord, cerebral axis, or brain, we have to consider the tracts as different in their structure from those conveying motor impulses, and as consisting of a series of short neurons closely connected but with very numerous and widespread connections? Is it not probable that the result of this arrangement is to secure a diffusion of single sensations to various reflex, vaso-motor, trophic, and automatic mechanisms, as well as to the organ of conscious perception? And is it not also evident that this view of sensory diffusion explains the apparent inconsistency

at present prevailing between the clinical symptoms observed in Brown-Séquard paralysis and the pathological degenerations occurring in that disease?

He concluded, that, in the conduction of sensory impulses to the brain cortex, a large number of different neurons are concerned, which are located in the gray matter and in all the various columns of the spinal cord, and that there are no true sensory columns or long continuous sensory tracts between the spinal cord and the cerebral cortex.

PRIMARY IDIOPATHIC HYDROCEPHALUS IN ADULTS.

DR. MORTON PRINCE, of Boston, reported three cases with autopsies, besides two others which terminated in recovery. The first case followed trauma and simulated latent abscess with secondary meningitis of the base. Trephining was done with negative results. At the autopsy the ventricles were found dilated to three times their normal size, the convolutions flattened, and sulci almost obliterated. The same condition was found in the second case. The third case followed sunstroke and was of the external variety, the meshes of the pia and arachnoid being filled with fluid so as to resemble a layer of jelly. There is an acute and a chronic form; the acute simulates the purulent form of meningitis, but differs from it in its course and the variability of the symptoms. The chronic simulates and is usually mistaken for cerebral tumor. The affection is common but not usually recognized.

DR. COLLINS felt certain that there were chronic conditions of this affection. He cited a case which presented all the characteristics of hereditary cerebellar ataxia, in which at the autopsy only ventricular distention was found.

The PRESIDENT asked Dr. Collins if microscopical examination had been made of the brain or cord, and was answered in the negative.

DR. SACHS said, that as the examination was incomplete, Dr. Collins's conclusions should not be accepted as final.

DR. P. C. KNAPP said that the reader of the paper had omitted to speak of lumbar puncture in differential diagnosis between meningitis and effusion. The negative findings are often important.

DR. PRINCE in closing the discussion said that unquestionably there is a chronic form. The principal differential point is in reference to the variation of symptoms from time to time in effusion.

SPINAL LEPTOMENINGITIS.

DR. FRANK R. FRY, of St. Louis, reported a case of purulent spinal leptomeningitis. The source of infection was a slight but rather chronic furunculosis on the back of the neck. The site of primary infection was the lumbar or lower dorsal region. The clinical history was that of an ascending paralysis with certain interesting features relative to temperature, etc., there was no cerebral involvement. Sections of the cord were presented, chiefly interesting in showing diffuse degenerations in the cervical and upper dorsal regions.

SUBARACHNOID SEROUS EXUDATION PRODUCTIVE OF PRESSURE SYMPTOMS AFTER HEAD INJURIES.

DR. G. L. WALTON, of Boston, read a paper with the above title, and said that in cases offering moderate febrile movement, prolongation of unconsciousness, and restlessness after trauma, it is of no vital moment

whether we adopt the term contusion, bruising, or laceration; but when to these symptoms local paralysis is added the question of operation arises and exact ideas of the pathology become important.

Operation over the area indicated sometimes shows only a tense dura, incision of which is followed by a gush of serum. Under the arachnoid membrane the greater part of the cortical cerebro-spinal fluid is collected. Serum may be exuded into the subarachnoid space as well as transuded, and sometimes the swollen and congested brain found under the fluid on operation shows that we have to do with an exudation resulting from increased blood-pressure, rather than with a compensatory process. Little attention has been paid to this process. The edema of Bullard accompanying hemorrhage is analogous; the serous meningitis of Quincke is analogous if not identical, in so far as he includes external meningitis, but he does not refer to this class of cases.

The following cases were mentioned: A boy of six years was struck by a bicycle at noon one day, was restless and drowsy, and on the following day became unconscious, with unilateral paralysis including the face. Operation was considered but postponed. The paralysis had disappeared within four days.

A child, three and a half years old, fell from a swing, striking the head; was drowsy, and the next day one arm was paralyzed. The paralysis began to lessen on the third day, and rapidly disappeared.

A young woman fell, striking the head violently. Unconsciousness, restlessness, vomiting and hemiplegia appeared. Operation revealed tense dura, incision of which was followed by a gush of serum. There was relief of pressure symptoms, but death ensued from the underlying condition.

His conclusions were: (1) a severe blow may result in local bruising and congestion with subarachnoid serous exudation; (2) the fluid may be imprisoned and cause focal paralysis; (3) the process is not compensatory, and is allied to the serous meningitis of Quincke; (4) the lesion is self-limiting; (5) diagnosis from hemorrhage is difficult, a typical course, absence of steady increase of symptoms, and persistent sensitiveness point to serous exudation; (6) immediate operation is not necessarily indicated in focal paralysis, though perhaps always justifiable; (7) this condition is specially to be borne in mind before operating on children and young adults.

Dr. J. J. PUTNAM, of Boston, had seen several cases in which such a diagnosis could be borne out, but there was shifting of symptoms, which was important. He had witnessed an autopsy on a woman who after influenza developed localized twitching of arm, leg and face every twenty minutes; twenty-four hours later, hemiplegia and rise of temperature. There were only edema and a wet soft brain. There was no local accumulation under the pia. He thought the convulsions and hemiplegia were due to the general edema. The pathology in these cases is not clear.

Dr. C. A. HERTER, of New York, believed that local effusion could give rise to these symptoms and spoke of a case of extreme general edema of the arachnoid following syphilis. There was some doubt as to whether the fluid is a simple effusion or an exudate. An inflammatory process, however, could not occur so rapidly. It might possibly be due to cerebral anemia. Pronounced general edema of the brain in children may be unaccompanied by any cerebral symptoms.

Dr. B. SACHS, of New York, said the theory was not new. After head injuries, three possibilities were to be considered: hemorrhage, local edema and purulent meningitis. The view of Dr. Walton was natural and plausible, and he agreed with his views as to differential diagnosis. He would not operate on the skull too soon, but would wait until positive of serious damage to the brain, not until after the lapse of forty-eight hours or several days.

Dr. HUGH T. PATRICK, of Chicago, added a case almost exactly like that of Dr. Prince. A child received a fall which was not severe, in the latter part of the afternoon, after which he played about as usual. At the supper table he suddenly let fall a fork from his right hand, and soon thereafter had a one-sided fit. Following this he became stuporous, and when seen several hours later was almost comatose, but a distinct hemiplegia was made out. Operation was declined by the family, and two days later the child was absolutely well. A localized edema is the only possible explanation of such an occurrence.

Dr. JOSEPH COLLINS, of New York, related the case of a man fifty years of age, who fell and struck his head in the left parietal region. This was followed by shock, stupor and paralysis of the right upper extremity. At the autopsy there was some localized serous exudation, which was evidently of inflammatory origin.

Dr. J. J. PUTNAM had seen venous hemorrhage into the pia which was accompanied by hemiplegia.

Dr. EDWARD B. ANGELL, of Rochester, asked Dr. Walton if there was any temperature record, to which he replied that there was slight rise of temperature.

The PRESIDENT thought that the question of localized edema should be one of fact and not of theory. He had seen three cases operated upon in which apparent inflammatory edema was found. He had also observed a case in which there was a very large amount of edema involving the entire hemisphere around a very small tumor.

FOCAL CORD LESIONS.

This was the title of a paper by Dr. F. W. LANGDON, of Cincinnati.

Two cases were reported: (1) Lumbar poliomyelitis anterior subacute in a white man of forty-four years without syphilitic or other dyscrasia. Onset gradual, with numbness and coldness in left toes and increasing weakness at left ankle. Five weeks later thermo-anesthesia over both legs. Tactile and pain senses normal. Foot-drop, muscular weakness and R. D. No bladder or rectal symptoms. Knee-jerks active. Ankle clonus absent. Recovery complete in about two months. The lesion was considered primarily a thrombosis in fourth and fifth lumbar segments.

(2) Traumatic poliomyelitis of cervico-dorsal cord without vertebral fracture. The medico-legal aspects of the case were important as furnishing additional proof that organic damage of the cord may occur in the absence of fracture of the bony canal.

ANESTHESIA IN SPINAL DISEASES.

Dr. P. C. KNAPP, of Boston, read this paper. He referred to the researches of Ross, Thorburn, Starr and others. In syringomyelia the distribution of the anesthesia is more apt to follow another type than in cerebral disease in which the boundary of the anesthesia is at right angles to the axis of the limb. Two

cases were reported and many others cited, proving this distribution.

DR. B. SACHS referred to cases of spinal origin, but which did not seem to be of spinal type, but which he had good reason to believe to be a syphilitic affection of the cervical region of the cord. This type closely resembled syringomyelia. He did not like the term "cerebral anesthesia" but preferred "regional anesthesia."

The PRESIDENT said it was practically impossible to lay down an accurate diagram of the anesthetics from various regions of the cord. Individual variations must be considered and admitted. Irregularity in distribution is characteristic of spinal anesthesia.

SYRINGOMYELIA.

DR. HUGH T. PATRICK reported the following case: A man of forty-four years began to be weak in the legs ten years before, which gradually increased until he walked with difficulty. A year ago the hands also began to be affected. Examination showed spastic paraplegia with weakness of the grasp and slight atrophy of the small hand-muscles. There was a band of anesthesia about the trunk and extending on to the inner surface of the arms, an area of analgesia covered this and extended beyond it about four inches on the trunk and two inches on the arms. This distribution of sensory blunting is exactly the same as that which has been described by Laehr and the author as occurring in tabes, except that in the latter disease the band of analgesia is much narrower than that of anesthesia.

SO-CALLED POLIENCEPHALITIS SUPERIOR AND INFERIOR.

DR. PATRICK reported a second case, that of a woman of thirty, who was attacked with bulimia, following which complete external ophthalmoplegia and incomplete bulbar paralysis developed. She died of respiratory failure about two months after the beginning of the disease. The autopsy revealed nothing. Microscopical examination showed all the arterioles and capillaries of the bulbo-fontaine region to be enormously distended. Other signs of inflammation were absent; there was no degeneration of fibres, and the cells of the various nuclei were all normal. The author considered the case to be one of transition between the so-called acute polienccephalitis and poliomyelitis on the one hand, and so-called asthenic bulbar paralysis on the other. He thought the disease essentially toxic, and suggested as a therapeutic measure the so-called "washing of the blood," that is, copious phlebotomy with simultaneous transfusion or the subcutaneous injection of salt solution.

AUDITORY APHASIA

was the title of a paper by DR. HOWELL T. PERSHING, of Denver.

He said that auditory aphasia is the sum total of speech defects due to a lesion of the auditory centre for words; it is a more precise term than sensory aphasia and more comprehensive than word-deafness.

The reader reported a case in which the symptoms were word-deafness, verbal amnesia, jargon paraphasia, paralexia, loss of comprehension of print, and agraphia, with retention of ability to copy Roman letters into script and with no visual defect whatever.

The impairment of all ways of using language, so

often observed as a result of an auditory lesion, was explained as due to the fact that the auditory centre is normally active in spontaneous speech, reading and writing, as well as in the comprehension of speech.

DR. W. T. WORCESTER, of Danvers, Mass., reported three autopsies in patients with sensory aphasia. There were softening and atrophy of the left first temporal convolution. He also mentioned a case of subcortical aphasia. The patient could not speak and had no comprehension of spoken language. He had right hemiplegia. At the autopsy softening of the external capsule and lenticular nucleus was found.

DR. CHAS. K. MILLS, of Philadelphia, agreed with the view of Dr. Pershing, and said that in such cases all forms of language might be affected.

DR. PHILIP ZENNER, of Cincinnati, referred to a case with frequent attacks of word-deafness and spasm of the right side of the tongue and face. At the autopsy a tumor was found in the lower part of the Rolandic fissure resting upon the first temporal convolution.

DR. COLLINS said that the auditory centre was localized in too small an area. The speech area is purely a sensory one. There is only one variety of aphasia and that is sensory.

DR. PERSHING, in closing the discussion, said that he had attempted in his paper to combat the views expressed by Dr. Collins.

(To be continued.)

Recent Literature.

A Treatise on Surgery. By American authors. Edited by ROSWELL PARK, M.D., Professor of Surgery and Clinical Surgery, Medical Department, University of Buffalo, N. Y. In two octavo volumes of 1604 pages, with 786 engravings and 37 full-page plates in color and monochrome. Philadelphia and New York: Lea Brothers & Co. 1896.

Dr. Park has aimed to place at the disposal of the medical profession a work containing a condensed but complete account of the theory and practice of the most advanced knowledge of surgery, as well as a text-book meeting the requirements of students seeking the advantages of our best medical institutions, and one furnishing full practical information to the general practitioner, whose duties frequently require surgical knowledge.

To accomplish this the author has thought it wise to avail himself of the knowledge, skill and experience of those best fitted to contribute to a work of this character. His own reputation has enabled him to associate with himself some of the most distinguished members of the profession in this country. The list of contributors consists wholly of men of national reputation, and many especially identified with the subject assigned them. The work is published, as stated above, in two volumes.

Volume I is devoted to General Surgery, and is classified as follows, many of the chapters being written by Dr. Parks himself: Part I, Surgical Pathology. Part II, Surgical Diseases, including surgical fevers, septic infection, syphilis, gonorrhea, shock, collapse, acute intoxications, delirium tremens, etc. Part III, Minor Surgery, Surgical Diagnosis, and the details of

the proper method for recording a surgical case. Part IV, Injury and Repair. Part V, Surgical Affections of the Tissues and Tissue Systems, including cysts and tumors, diseases of the skin, muscles, tendons, bursæ, lymphatics, veins, arteries, joints, bones, fractures and dislocations.

Volume II contains the articles on Special or Regional Surgery. Here are described diseases and injuries of the head, spine, heart, pericardium, large blood-vessels, respiratory organs, face, neck, chest, mouth, tongue, teeth, jaws, abdomen, hernia, rectum, genito-urinary organs, female reproductive organs and breast, amputations, orthopedic surgery, plastic surgery, eye, ear and skiagraphy.

In the above table of contents the chapters which attract attention as unusual and new are those on Surgical Pathology of the Blood (a brief *résumé* of what has been done on this subject), the Bacteriological Part of Inflammation, Infection, Acute Infection and Intoxications, Surgical Sequelæ of Non-surgical Diseases, Surgical Diagnosis and Significance of Pain, the Methodical Report of a Surgical Case, Gun-Shot Wounds, and the articles on Muscles, Tendons, Bursæ and Fasciæ. It is also unusual in recent years to include in works of this character articles relating to such special branches of medicine as the eye, ear and skin.

The articles are well written and illustrated, but are with few exceptions too condensed for readers other than medical students, or those wishing only a summary of the lesion or disease under consideration. To one in the position of the former it is, of course, desirable to present a subject in as clear a manner as possible and stripped of all doubtful and conflicting opinions. The classification of subjects is excellent. The most advanced ideas and methods appear, but full detailed descriptions are usually not given. This is necessarily so in many cases. The colored plates often show a brilliancy and variety of hues rarely seen in the natural specimens. The value of the book would have been, perhaps, increased by the introduction of marginal references to the literature of the subjects under consideration, especially when important or recently acquired facts relating to pathology, operative work, bacteriology, diagnosis or treatment are given in a few lines. The book is one which will undoubtedly have an extended sale.

Five Years' Work in Surgery. Comments and Deductions Based upon a Series of Thirteen Hundred and Eighty-seven Operations. By HORACE PACKARD, M.D., Professor of Surgery, Boston University School of Medicine; Surgeon, Massachusetts Homœopathic Hospital; Consulting Surgeon, Westboro Hospital for Insane; Consulting Surgeon, Newton Hospital. Boston: Press of Samuel Usher.

In this little volume the author presents the result of his work during the past five years. It is pleasingly written, and attractive from the chromolithographs and the heliotypes and half-tones which are of value in illustrating unique or interesting cases. A fair presentation to the profession of one's work in medicine or surgery, with the deductions therefrom, cannot help being of value.

The author records in a tabular form 1,387 operations, with a mortality of 3.96 per cent. He includes in this table of operations a number of cases that would better have been omitted; for example,

the application of an angular splint (Levis) to a fracture of the arm should not be classed as an operation involving life, and the note that "no suppuration occurred" seems hardly necessary. Again, the classing of a fracture of the metacarpal of the little finger as, "Reduction, Levis splint—operation, 1; cured, 1; no suppuration, 1" throws light upon his percentage (3.96) of mortality.

We congratulate Dr. Packard on his five years' work in surgery, and are indebted to him for his carefully prepared brochure.

Elementary Anatomy and Surgery for Nurses. A Series of Lectures delivered to the Nursing Staff of the West London Hospital. By W. MCADAM ECCLES, M.S. (London), F.R.C.S. Eng.; Assistant Surgeon to the West London Hospital; Assistant Surgeon to the City of London Truss Society; Surgeon to the St. Marylebone General Dispensary; Late Senior Assistant Demonstrator of Anatomy, St. Bartholomew's Hospital. London: The Scientific Press, Limited. 1896.

This little book is an excellent elementary outline of human anatomy in its relations to minor surgery, bandaging, and the work of a general surgical nurse. The descriptions are clear, simple and well adapted to the grade of instruction for which the lectures are intended.

The book is thoroughly practical, and ought to prove a help in mastering the principles of intelligent surgical nursing.

The Principles of Theoretical Chemistry, with Special Reference to the Constitution of Chemical Compounds. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. Fifth edition, thoroughly revised. Philadelphia and New York: Lea Brothers & Co. 1897.

In preparing this edition the author has adhered strictly to the original plan of the book, which is essentially "a brief treatise on those facts and speculations that have to deal especially with the problem of the constitution of chemical compounds." It is sufficient, in the case of a work so well known, to state that it gives a very clear and concise presentation of the fundamental principles upon which the modern theory of chemistry is based. The text of the present edition does not differ materially from that of the preceding edition.

A Manual of Physiology, with Practical Exercises. By G. N. STEWART, M.D., Professor of Physiology in the Western Reserve University. Philadelphia: W. B. Saunders.

The full title of Dr. Stewart's book indicates its chief excellence: it is a manual of physiology, *with practical exercises*, and the author deserves and will receive the thanks of laboratory men for bringing experimental and so-called didactic physiology into a union, which, in an elementary text-book, is as rare as it is desirable. The experiments are introduced in such a way that they may be used separately, in the laboratory, or as illustrations to the clear and well-arranged text. We find, throughout, the investigator's point of view, which, indeed, was to have been expected from the author of many valuable researches in physiology. The illustrations are numerous and well chosen.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 23, 1897.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.**SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.**All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.**All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.**Remittances should be made by money-order, draft or registered letter, payable to*DAMRELL & UPHAM,

EXPERT TESTIMONY.

THERE can be no question that the matter of medical expert testimony is exciting a degree of discussion both among the medical and legal fraternities which must in time be productive of some practical reform. The methods of testimony now in vogue in most of our States are clearly unfair to the physician who is called upon for an opinion, and prejudicial, we believe, to the ends of justice; and yet so difficult is it to do away with a long-established custom, even if manifestly imperfect and unjust, and so difficult to substitute a better system, that we find ourselves in the anomalous attitude of complete dissatisfaction with the present state of affairs, and of impotence in effecting a change.

This unquestionably is due to many factors, bound up chiefly with the established customs of the courts. It is clearly evident that however much the body of right-minded physicians may desire reform, such reform will never be forthcoming until the representatives of the law are equally solicitous; and just here, no doubt, is a difficulty of much magnitude. In any given case, theoretically the interest of a lawyer and that of a physician should be identical, namely, to arrive at *facts*. Practically the lawyer wishes to arrive only at those facts which strengthen his side of the case, and almost inevitably the "unprejudiced" physician is drawn into the net and finds himself on the very verge of pleading the case in conjunction with his legal *confrère*. This outcome is inherent in the system, and human nature is often, as we know, too weak to withstand the strain, and the so-called medical expert unequivocally, though usually unintentionally, becomes the partisan which a lawyer confessedly and properly is. To the attorney pleading a case this is an evident advantage; to the physician it is, or should be, humiliating. It is clear at a glance that a systematic protest must come from physicians, and is not to be expected to come from lawyers. It is the dignity of the *physician* which suffers; he it is who finds himself so often in a ridiculous position.

Advisable, therefore, and necessary for final results as co-operation with the legal profession is, we as physicians should not abate our efforts in the slightest because such co-operation is not immediately forthcoming. The agitation has unquestionably begun, and a number of vigorous and logical papers are at hand from men of high standing in the medical profession. We would call attention particularly to an article by Putnam, which appeared in this JOURNAL of October 22, 1896, entitled "Remarks on the Opportunities and Responsibilities of Neurological Experts with regard to Medico-legal Testimony." The paper is replete with suggestions of value and temperate protest against the present state of affairs. A second paper is that of Dr. Walter Lee Munro, of Providence, being an address delivered before the Rhode Island Medical Society in June of this year, and published in the *New York Medical Journal* of July 31st. Dr. Munro chose as the subject of his address "The Physician upon the Witness-stand"; and we have seen no better or more scholarly arraignment of the present system of expert testimony. It is, in fact, conclusive, and admirably illustrated by two cases in which certain medical testimony appears in the full measure of its absurdity. He makes a vigorous appeal for a fairer system, which will tend, at least, to re-establish the medical expert in the position of dignity which was his many years ago, and from which he has so pitifully fallen.

A still more stirring appeal for reform comes from the pen of Van Gieson, in conjunction with Sidis, in the April number of the *New York State Hospitals Bulletin*, in a paper on "Epilepsy and Expert Testimony." The case which forms the basis of Van Gieson's argument is one now famous, particularly from the fact of the part played in the final verdict by so-called expert testimony. In brief the details were as follows: an ignorant young woman was seduced by her lover, and after various unsuccessful attempts to induce him to marry her, finally in a public place cut his throat with a razor, leading to his almost immediate death. The trial, conducted from a purely legal standpoint, disclosed the fact of a strong motive for the crime, and the verdict, on the evidence then presented, was murder in the first degree, with a sentence of death. Pending the execution of the sentence, a strong sentiment of mercy gained a foothold in the community, and this, associated with the possibility of showing an epileptic tendency with temporary mental aberration, led to an appeal which finally resulted in a second trial. The medical witness in this trial was prominent; a detailed family and life history of the defendant was introduced,¹ and a plea of irresponsibility made on the ground of insanity—so-called "psychic epilepsy." In this trial the testimony of the previous one was, for the most part, ignored. In other words, as Van Gieson and Sidis put it: "In the first trial no excuse was presented and sentence of

¹ See in same number of *State Hospitals Bulletin* a careful paper by Hrdlicka on "The Medico-legal Aspect of the Case of Maria Barbella."

death was pronounced. In the second trial it appears that a tissue of 'psychic epilepsy,' ingeniously woven, but very flimsy when analyzed by the data in the first trial, allowed the jury to satisfy its conscience in expressing the sentiment of female palliation in a verdict of 'not guilty,' resulting in acquittal."

It is not our purpose to discuss the arguments for or against the above crime having been committed during a period of aberration; for that we would refer the interested reader to the respective papers of Van Gieson and Hrdlicka, we wish simply to call attention to the fact that here is a case which admirably serves as an example of the uncertainties of so-called justice in its relation to medical expert testimony, and of the absolute necessity for a discriminating and scientifically conducted investigation by competent and unbiased persons of all cases in which a medical opinion is to have weight with the jury.

What possible remedy is there for so unfortunate a state of affairs as a study of the Barbella case discloses? Van Gieson and Sidis offer a solution which certainly must appeal to every right-minded person, whether or not he may consider it possible of immediate consummation. In general, they would wish to have an official body appointed, best by the State, and naturally paid by the State, whose function it should be to investigate in detail and from every point of view cases given it, or any of its members, for consideration. Of the duties of such a body, which they would tentatively designate "The State Commission of Medico-legal Inquiry," they write as follows:

In any criminal case where questions of scientific nature arise, the determination of these questions shall fall within the province of the commission, which shall work out the scientific data and *render its general conclusions thereon*, so that the court and jury shall have a solid basis to determine their verdict in connection with the ordinary testimony.

Although in no wise tending to assume any of the prerogatives of the court, such a body might also advise as to the admission of cases for scientific inquiry and prescribe how this should be done in order to dispense with the authority of the dictatorial and *ipse dixit* "science" of "expert" testimony.

Such an official body, best appointed by the State, might undertake the investigation itself or assume the responsibility of its direction and control; in the latter case scientific men would be retained whose career had gained respect in the scientific world and whose publications, investigations and real knowledge of their subjects would make their researches and opinions authoritative. This would reduce to a minimum the evil of having the second-hand knowledge of would-be "experts" whose shrewdness had gained them a reputation with the laity, that has no knowledge of pathological phenomena. After the commission or official body conducting scientific inquiry in legal cases has directed or undertaken the research, the complete data of such inquiry, together with the general conclusions therefrom, could be submitted in a dispassionate, truth-searching, scientific paper as to whether the plea of insanity is right or wrong; such a paper will serve as a guide for the jury or the judge who, under the recommendation of the commission, shall accord to the culprit the measure of punishment, restraint and care the case may demand.

That the establishment of some such commission would be of inestimable value can, we think, scarcely be questioned, nor do we believe it is too utopian to hope that a plan at least approaching this in scope may be the not-distant outcome of a concerted effort at reform.

A less radical change, and one which, if but temporary, would be a decided step in advance, is that suggested by Mather, quoted by Munro in the paper to which we have already alluded. After speaking of the present system, Mather says: "The remedy lies in the designation by the court, in each case, of the experts who shall be called upon to testify. Whether agreed upon by the parties or selected by the judge, the experts should receive their appointment from the court. They should be officers of the court, sworn and acting as its commissioners for the better ascertainment of the truth." Munro goes on to say that Mather would thus "insure the selection of actual experts," whose impartiality and disinterestedness could be counted upon, and hence all partisanship being out of the question, the lawyers for each side would unite in desiring the selection of the expert from those most competent.

The objection made by lawyers to such propositions is that they restrict the inalienable right of the litigant to call any witnesses he may see fit. It seems to us, however, that the litigant's right to call witnesses would remain unimpaired, although the importance of such witnesses as experts might be interfered with.

The almost universal verdict of disinterested writers on the matter is that the present mode of partisan expert testimony is, in its nature, dangerous and detrimental both to the dignity of the so-called expert and to the cause of justice, and that a reform along the lines indicated in the foregoing quotations is heartily to be desired. Unquestionably we should help along such reform by every means in our power. In the meantime our efforts should be unsparing in demonstrating to the body of lawyers and to the laity that a strict virtue and integrity and judicial fairness lies behind our testimony, no matter by whom we may be summoned to appear. Just here a plea may rightly be made to the whole body of physicians, a protest which constant occurrences in the courts amply justify. It is, simply, that physicians in good standing shall testify only in those cases in which they have special knowledge; that to qualify as an expert shall mean a distinct and painstaking training along certain definite lines. In other words, that the dignified term "Expert" may not be robbed of the last vestige of its meaning.

We cannot do better than quote in this connection a passage from Putnam's paper, to which the reference has already been given. After suggesting certain remedies, he says: "It is probable that these attempts on the part of trained experts to improve their own testimony and increase the respect in which it was held would have the indirect effect of discounting the testimony of those who are less well qualified.

"It is as absurd for a surgeon, however considerable his experience, to assume to pass judgment on a difficult question of neurology or psychiatry as it would be for the neurologist to give a critical opinion on the merits of different incisions for laparotomy; and the fact that this absurdity is not generally recognized is

but another illustration of the low respect in which medical testimony is held."

Should such advice as this be conscientiously followed, we might at least flatter ourselves that a first step had been taken towards an ultimate reform, such as Van Gieson and Sidis so forcibly bring before our attention.

THE INFLUENCE UPON NERVOUS AFFECTIONS OF OPERATIONS UPON THE FEMALE PELVIC ORGANS.¹

THE general trend of medical opinion of late years has been pretty steadily against the efficacy of operations upon the pelvic organs, especially oöphorectomy, as a cure for nervous or mental affections, always excepting those cases where disease of those organs demands such operation, independently of the nervous condition. At a meeting of the Association of American Physicians, in 1891, Dr. Wharton Sinkler, of Philadelphia, took the ground that it was unjustifiable to remove healthy ovaries in cases of nervous disease, and the late Dr. Lusk, of New York, said that he was tempted to regard such a proceeding as malpractice. A recent inquiry conducted by Drs. Angelucci and Pieraccini of the provincial asylum at Macerata, Italy, has afforded considerable information in the way of the accumulation of statistics of cases in sufficient number to warrant certain definite conclusions.

The data which they present are based upon reports made to them by the heads of public and private asylums and psychiatric clinics in various countries, embracing a total of 115 cases in which surgical operations were performed upon the female sexual organs, either healthy or diseased, to combat some nervous disorder or to remove diseased organs. One hundred and thirty-seven of the asylums and clinics interrogated had had no cases of the sort. Out of 76 alienists, directors of asylums or clinics, 56 more or less strongly disapproved of such operations, twelve had not had sufficient experience to warrant a personal opinion, five were uncertain, and only three favored such operations in the treatment of hysterical conditions.

Of the 115 cases six were subjected to a simulated operation for the relief of hysterical conditions. Of the remaining 109 cases 65 had healthy organs removed for the cure of nervous conditions, eighteen nervous patients had diseased organs removed, and 26 women neither insane nor hysterical had diseased organs removed. Forty-one cases of hysteria had healthy organs removed on account of the nervous trouble; of these 17 became insane, 10 grew worse, 11 were unaffected and three cured. Eighteen cases of hysteria had diseased organs removed; three became insane, six were unaffected and nine were cured. Twenty-four women neither hysterical nor insane became insane after diseased organs were removed, and two others became neuropathic. Twenty-four insane women had healthy organs removed for the cure of their insanity; 19 grew worse or were unaf-

fectured, five improved or were cured. In only 17 cases, therefore, were the results favorable, and of these only three were cured of hysteria or other nervous disturbances by the removal of healthy organs. Inasmuch as six cases of hysteria were apparently cured by simulated operations the investigators naturally inquire how far, in these cases where actual operation was done, the influence of suggestion may have been felt.

As a result of their inquiry Drs. Angelucci and Pieraccini conclude that the removal of the uterus or its adnexa, if in a healthy state, is to be proscribed as a means of treatment of hysteria or insanity, and that the existence of hysteria is almost a contraindication for any serious gynecological operation. If any such operations are undertaken the indications must depend upon the gravity of the uterine or ovarian disease, and not upon any hope of a favorable influence upon the nervous conditions; the only favorable influence upon these latter conditions is in the way of suggestion. If all other means have failed in combating hysteria, a simple incision, simulating a laparotomy, may sometimes be admissible by way of suggestion.

Taking the statistics, as the present writers have done, from reports furnished by asylums and psychiatric clinics, it is possible that the proportion of cases injuriously affected by such operations is unduly large, since the physicians in charge of such institutions might have less opportunity for observing the cases which were entirely cured of any nervous or mental trouble after the operation. Nevertheless, any serious cases of nervous or mental trouble which were cured by operation would naturally have come under the observation of these men during the time when they were suffering from such trouble, so that the proportion is really nearer the truth than it might at first seem. Furthermore, as is well known, the statistics of cases from surgical reports only are too often based upon the immediate results of operation, without waiting to note the later developments in regard to any nervous troubles. It is therefore safe to accept the conclusions of Drs. Angelucci and Pieraccini, as endorsing the belief that the removal of healthy organs for the relief of nervous or mental troubles is wholly unjustifiable.

MEDICAL NOTES.

PRESIDENT FAYRE'S GIFT TO A MOSCOW HOSPITAL. — The President of the French Republic has left 5,000 roubles for the French hospital at Moscow, and 6,000 for different charitable societies in Russia succoring French people.

THE UNIVERSITY OF CALIFORNIA REJECTS THE PETITION OF THE HAHNEMANN HOSPITAL COLLEGE. — At the last meeting of the Regents of the University of California fourteen members of the Board voted against the admission of the Hahnemann Hospital College to affiliation with the University, and only four in favor of such admission. The position of the Hahnemann Hospital was therefore rejected,

¹ Rivista Sperimentale di Freniatria, xxiii, 290, June, 1897.

and the vote is regarded as one of absolute confidence in the present Medical Faculty.

YELLOW FEVER IN THE SOUTH.—The cases of yellow fever in New Orleans have shown generally a very mild form of the disease. On September 21st there were nine new cases and no deaths in that city. The board of health has had no difficulty in placing each case in efficient quarantine, and local alarm is diminishing. Various towns in the surrounding country have withdrawn restrictions against the receipt of freight from New Orleans. At Edwards, Miss., on September 21st, five or six new cases were reported. The report of the occurrence of a case at St. Louis has proved to be erroneous. The situation, as a whole, may be said to have markedly improved since last week. The season of the year and the low temperature are against the active propagation and spread of this disease, and against its assuming a virulent form.

NEW ENGLAND.

THE BOARD OF LUNACY AND CHARITY EXONERATES ITS EMPLOYEES.—The Massachusetts Board of Lunacy and Charity have voted that their employees were not engaged in improper lobbying during the session of the last legislature. Notwithstanding this vote of exoneration, the general feeling seems to be that the employees are likely to be more circumspect in the future.

NEW YORK.

INSUFFICIENT SCHOOL ROOM.—The public schools were opened for the season on September 13th, and, notwithstanding the fact that three new school-houses and thirty-five thousand seats have been added to the school accommodations during the past summer, there were still more than eight thousand children who applied for admission turned away on account of lack of room. There are, however, thirty-two school-houses now in course of erection, and when they are all completed it is believed that every child of school age will be given a seat, unless the population makes an unprecedented advance. For a number of years the city has been unpardonably behindhand in providing sufficient accommodations for the public-school children, and it has taken a long time and a very large expenditure of money to adequately meet the demand upon it in this department.

MIDWIVES IN NEW YORK.—The recent developments indicating that the midwife Augusta Nack, who, with Martin Thorn, has been indicted for the murder of Guldensuppe, the Turkish bath employee, was also a professional abortionist has directed renewed attention to the existing abuses in regard to midwives in New York. The records of the Bureau of Vital Statistics show that out of the 55,000 births reported in the city last year, more than 25,000 were reported as attended by women of this class. There is good reason to suppose that at least half as many more were attended by midwives which were never reported at all. The hopelessness of even securing a conviction for failure to report a birth leaves these women almost unlimited

freedom. As to how many of them there are in New York there is no means of knowing, though it is believed that two thousand would be a low estimate. At the Health Department, where they are supposed to register, 950 have signed within the past three years.

The County Medical Society has made several attempts to have a law passed requiring midwives to pass an examination before a properly constituted medical board, but always without success. There can be no doubt that such a law would decrease the death-rate of mothers and infants, prevent much of the disease and deformity common among children of the tenements, and also diminish the number of criminal abortions. There are several so-called schools of midwifery in different parts of the city which derive a profitable trade from the sale of "diplomas" to midwives who are supposed to have pursued a course of study in them; yet there is no law to prevent them from issuing their certificates. Such "diplomas" have no value whatever, and could be given out by any one who chose to do so.

In speaking of this matter, Dr. George B. Fowler, Commissioner of the Board of Health, said recently: "A woman does not require a diploma to become a midwife. Any woman can practise who wants to, whether she knows anything about midwifery or not. All the law requires is that she be registered and that she report all births at which she is in attendance. We are constantly receiving complaints from reputable physicians regarding the evil work of these midwives. . . . A great many lives are lost in this way every year. Sometimes it is the mother and sometimes it is the infant who dies. Sometimes it is both. What we should have is a law to be general throughout the State, which would require all persons practising midwifery to pass an examination before a medical board appointed by the State Board of Health or some other such body. There are five counties in the State now which regulate midwifery by statute. A law such as is contemplated would sift out the incompetent and ignorant, and substantially decrease disease, deformity and the death-rate. There is great need for this law, and it should have been passed years ago."

One of the saddest features of the malpractice of ignorant midwives is met with in the large number of children who become wholly or partially blind through their neglect. At the New York Eye and Ear Infirmary recently one of the physicians had three such cases in a single afternoon, and at the Manhattan Eye and Ear Hospital more than fifty cases of the kind come under observation every year.

DEATH AT AN ADVANCED AGE.—Sarah Elmen-dorf, a negress and a former slave, died at the reputed age of one hundred and ten years at Kingston, Ulster County, on September 15th.

DEATH OF A PROMINENT PHARMACIST.—David Hays, for many years one of the most prominent druggists in New York, died on September 16th, at the age of seventy-eight. He was especially devoted

to the interests of the College of Pharmacy, and for a long time was treasurer of that institution.

DEATH OF DR. RENDELL.—Dr. John Rendell, of Bedford Avenue, Brooklyn, died at St. John's Hospital in that city on September 16th, from injuries received in a runaway accident the day previous. He was fifty-seven years old and a graduate of the Long Island College Hospital. The cause of death was fracture of the skull.

Miscellany.

MONEY ROULEAUX.

THE Vienna correspondent of the *Medical News* is responsible for the following story:

Not long ago one of the distinguished clinical professors was summoned to the house of the Austrian member of the famous banking family of Rothschild. He was accompanied by a younger member of the profession who, while his chief was making the general clinical examination, proceeded to examine the baron's blood. The banker was extremely interested in the procedure, and when the examination was concluded asked what he had found. The assistant replied that he had found everything perfectly normal and healthy; that there was the usual number of red blood-corpuscles, showing no marked differences in size or shape, and there was a very normal tendency to the formation of money rouleaux. The distinguished patient, who is well acquainted with the hereditary failing of his family in the matter of successfully forming money rouleaux, but who did not realize that this tendency was so outspoken that it could be discovered on microscopic examination of his blood, was very much amused. He was at first inclined to consider the expression as not quite serious and as meant to stave off questions on the part of an inquisitive patient. When assured, however, that the description was eminently scientific, his admiration for the "new medicine" was correspondingly increased. "What is bred in the bone will out in the blood," I suppose received a striking exemplification for him. When the visit was over and the doctors were leaving the fee the younger man found in the envelope handed him by the baron's secretary was not smaller for his chance excursion all unwittingly into the atavistic peculiarities of the Rothschild family in his perfectly commonplace description of the results of a blood examination.

Correspondence.

OYSTERS AND TYPHOID FEVER.

Boston, September 17, 1897.

MR EDITOR: Comment has often been made upon the increase of typhoid fever in our cities in the autumn months, and this has been charged to several sources: first, the return of visitors from summer resorts where the sanitary conditions may have been defective; second, low water in wells in the rural districts and such parts of the more sparsely populated parts of the cities as are not furnished with public water supplies; third, milk, a very common cause, especially when the milk is supplied in cans, or bottles which have been washed in filthy water.

There is, however, another possible cause, which, in the light of recent investigations, is worthy of more careful attention, and that is the use of shell-fish obtained from waters known to be seriously polluted. September is the month in which typhoid fever begins to prevail with greater frequency. It is also the month in which, accord-

ing to popular opinion, it is safe and proper to eat oysters, and to continue their use until the following spring.

The recent report of the Local Government Board of England upon Oyster Culture and Disease shows that serious illness followed the eating of oysters procured upon the sea-coast near the outlet of the sewers of the town of Grimsby, and reports of Professor Conn and Dr. Foote, of Connecticut, give similar testimony in regard to oysters grown upon the shores of Long Island Sound. Still later, a physician of Bastia, in the Island of Corsica, reports an epidemic of typhoid which was traced to the eating of snails and limpets which were obtained near the mouths of the sewers of that city.

But the oysters of Grimsby are subjected to a mere fraction of the pollution which occurs in some of our own American oyster beds. The Narragansett Bay and Providence River have for many years been favorite fields for the oyster-gatherers, but these waters, having a moderate tidal flow, with sluggish currents, receive the entire sewage of Providence, Pawtucket, Worcester and other places having a population of nearly 300,000 inhabitants.

May not this fact account for some of the mysterious cases of typhoid, the source of which has been unrecognized? And in view of the fact that such oysters appear upon the bills of fare of most hotels and restaurants, is it not desirable that their sale should either be forbidden altogether, or that each sale should be accompanied with a printed caution, advising the consumer not to eat them uncooked?

Very truly yours,

BIVALVE.

RECORD OF MORTALITY

Deaths reported 3,511: under five years of age 1,418; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 746, consumption 375, acute lung diseases 257, diarrheal diseases 477, typhoid fever 86, diphtheria and croup

78, whooping-cough 33, cerebro-spinal meningitis 26, scarlet fever 21, malarial fever 17, measles 6.

From whooping-cough Chicago 9, Pittsburg 6, Brooklyn and Washington 3 each, New York, St. Louis, Baltimore, Boston, Providence, Fitchburg and Everett 1 each. From scarlet fever New York 7, Boston 3, Philadelphia and Lawrence 2 each, Chicago, Baltimore, Cincinnati, Providence, Fall River, Cambridge and Taunton 1 each. From cerebro-spinal meningitis New York 8, Boston and Lynn 4 each, Washington and Worcester 2 each, St. Louis, Nashville, Springfield and Malden 1 each. From malarial fever St. Louis 8, Philadelphia 4, Nashville 3, Chicago 2. From measles New York 3, Philadelphia, Pittsburg and Providence 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,982,524, for the week ending September 4th, the death-rate was 20.7. Deaths reported 4,362, diarrhea 1,001, measles 83, whooping-cough 62, diphtheria 57, fever 38, scarlet fever 31.

The death-rates ranged from 10.4 in Swansea to 37.5 in Hull; Birmingham 24.1, Bolton 22.8, Gateshead 25.3, Leeds 19.2, Leicester 23.8, Liverpool 28.1, London 17.1, Manchester 25.6, Newcastle-on-Tyne 26.6, Nottingham 21.0, Sheffield 25.1, Sunderland 27.2, West Ham 20.8.

METEOROLOGICAL RECORD

ing; N., snow. † Indicates trace of rainfall. — Mean for week.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 11, 1897, TO SEPTEMBER 17, 1897.

Leave of absence for one month, to take effect on or about the 20th inst., with permission to apply for an extension of one month, is granted **LIEUT.-COL. J. V. D. MIDDLETON**, deputy surgeon-general, chief surgeon, Dept. of California.

The leave of absence granted **CAPTAIN OGDEN RAFFERTY**, assistant surgeon, is extended one month.

A board of officers to consist of **MAJOR ALFRED C. GIRARD**, surgeon, **MAJOR JOSEPH K. CORSON**, surgeon, **MAJOR CURTIS E. M. MUNN**, surgeon, is appointed to meet at Denver, Col., on Wednesday, September 22, 1897, at 10 o'clock, A. M., for the examination of such officers of the medical department as may be ordered before it to determine their fitness for promotion.

CAPTAIN JUNIUS L. POWELL, assistant surgeon, Fort Riley, Kan., ordered to report to the president of the examining board, Denver, Col., for examination as to his fitness for promotion.

FIRST-LIEUT. JAMES M. KENNEDY, assistant surgeon, will be relieved from duty at Fort Missoula, Mon., and is ordered to Fort Washington, Md., for duty at that post.

Leave of absence for one month, to take effect about September 15, 1897, is granted **CAPTAIN ASHTON B. HEYL**, assistant surgeon, Fort Riley, Kan.

The leave of absence granted **CAPTAIN HENRY A. SHAW**, assistant surgeon, is extended one month.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE TWO WEEKS ENDING SEPTEMBER 11, 1897.

MURRAY, R. D., surgeon. To assume command of operations at Ocean Springs, Miss. September 7, 1897.

SAUTELLE, H. W., surgeon. Leave of absence granted by department letter of August 10, 1897, revoked, and directed to report at Bureau for special duty. September 8, 1897.

AUSTIN, H. W., surgeon. To report at Bureau for special duty. September 9, 1897.

CARTER, H. R., surgeon. To proceed to Ocean Springs, Miss., for special duty. September 6, 1897.

CARMICHAEL, D. A., surgeon. Leave of absence granted by department letter of August 6, 1897, revoked. September 7, 1897.

GLENNAN, A. H., passed assistant surgeon. To proceed to Grand Bay, Ala., for special duty. September 9, 1897.

WHITE, J. H., passed assistant surgeon. To report at Bureau. September 7, 1897. To proceed to Ocean Springs, Miss., for special duty. September 9, 1897.

CARRINGTON, P. M., passed assistant surgeon. On being relieved by Assistant Surgeon **TABB**, to report at Bureau for duty. September 10, 1897.

STONER, J. B., passed assistant surgeon. Directed to proceed to Chicago, Ill., and assume temporary command of Service. September 7, 1897.

GUIERAS, G. M., passed assistant surgeon. On being relieved by Assistant Surgeon **J. B. GREENE**, to proceed to New Orleans, La., for special duty. September 7, 1897.

KEDDINGS, H. D., passed assistant surgeon. To assume charge of Hygienic Laboratory during the absence of Passed Assistant Surgeon **J. J. KINYOON**. September 9, 1897.

GREENE, J. B., assistant surgeon. To proceed to Key West, Fla., for temporary duty. September 7, 1897.

TABB, S. R., assistant surgeon. To proceed to Evansville, Ind., and assume temporary command of Service. September 10, 1897.

MATHEWSON, H. S., assistant surgeon. To rejoin station at San Francisco, Cal. September 8, 1897.

BOARD CONVENED.

Board convened to meet at Washington, D. C., September 10, 1897, for the physical examination of candidates for appointment as second assistant engineer in the U. S. Revenue Cutter Service. Surgeon **C. E. BANKS**, Chairman, and Passed Assistant Surgeon **G. T. VAUGHAN**, Recorder.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 18, 1897.

H. LA MOTTE, assistant surgeon, was placed on the retired list September 15th for physical disability.

SOCIETY NOTICES.

NEW YORK STATE ASSOCIATION OF RAILWAY SURGEONS.—The seventh annual meeting will be held at the Academy of Medicine, New York City, on Tuesday, November 16, 1897, under the presidency of **Dr. J. Frank Valentine**, Chief Surgeon of the Long Island Railway.

C. B. HERRICK, Secretary.

THE TRI-STATE MEDICAL SOCIETY.—The ninth annual meeting of the Tri State Medical Society of Alabama, Georgia and Tennessee will be held in Nashville, Tenn., Tuesday, Wednesday and Thursday, October 12, 13 and 14, 1897.

FRANK T. SMITH, M.D., Secretary, Chattanooga, Tenn.

RECENT DEATHS.

CHARLES HENRY DAVIS, M.D., M.M.S.S., died in Worcester, September 16, 1897, aged fifty-one years.

JOHN BRAXTON HICKS, M.D., London, F.R.C.P., F.R.S., the eminent obstetrician and gynecologist, died on August 28th, at his residence in Lymington, Eng., aged seventy-two years. He was for many years connected with Guy's Hospital, having been appointed assistant obstetric physician in 1855, obstetric physician in 1870, and consulting obstetric physician in 1882. He retired from active practice about three years ago. Braxton Hicks played a prominent part in the history of obstetrics and gynecology in Great Britain, and his writings on these subjects are of great importance and value. He was an Honorary Fellow of the Royal Society, of the Obstetric Societies of Edinburgh, Berlin and Philadelphia, and of the American Gynecological Society.

BOOKS AND PAMPHLETS RECEIVED.

Albinism. By **W. H. Dap6, B.A.**, Montreal. Reprint. 1897.
Appendicitis. By **William B. Van Lennep, A.M., M.D.**, Philadelphia. Reprint. 1897.

The American Academy of Railway Surgeons. Report of the Third Annual Meeting, held at Chicago, Ill., September 23, 24 and 25, 1896. Edited by **R. Harvey Reed, M.D.**, Columbus, O. Chicago: American Medical Association Press. 1897.

Original Articles.

AN EXAMINATION OF HUMAN GAIT.¹

BY E. H. BRADFORD, M.D., BOSTON.

If the gait of pedestrians be watched, it will be noticed that there are variations, not only according to age, size and strength, but also in different individuals. These variations are at first so confusing that any classification seems impossible; but on further examination it will be seen that certain types can be determined.

If any one walking is seen from the side, it will be noticed that the body is kept erect, if the gait is a leisurely one. The thigh is advanced by the action of the psoas and iliacus, the rectus and tensor vaginae femoris muscles; the weight is first thrown upon the heel of the projecting leg, and the body brought forward by the push of the foot of the rear leg, which is bent at the knee. The projecting leg as it strikes the ground is usually straight, that is, not bent at the knee. This may be termed the erect gait, or straight-leg gait.

In faster walking, or in a slow gait in feeble persons, and in children, the weight of the body is frequently used as a means of propulsion. The individual leans forward, his body weight falling forward propelling him, being kept from falling to the ground by the interposition of the front leg, which is usually bent at the knee as the heel strikes the ground. The gait differs from a run, in that it is a true heel-and-toe gait, and not upon the front of the feet alone, as is the case in a run. This may be classed as the forward or bent-knee gait.

In strong and rapid walking both of these types are combined, the front leg is protruded as far as possible, and held straight, that is, not bent at the knee as the weight strikes the ground. The foot of the rear leg is used to propel with a vigorous push; the knee of the rear leg is straight, but slightly bent at the final strong push of the foot, the weight of the body falls forward, the trunk is inclined forward acting by its weight as an additional propelling force.

The angle the foot forms with the ground when the heel first strikes it, looked at from the side, varies in individuals. It is necessarily greater in long strides

than in short strides, and in the erect and the bent-knee gaits. It has been stated that, in normal gait, the projecting foot strikes the ground with the whole of the sole rather than with the heel alone. Instantaneous photography has disproved this except in an artificial gait, the parade step in the German army.

If those who are walking are looked at in front as they approach, it will be seen, from a little distance, that a noticeable angle will be made by the axes of the feet. This angle of divergence varies in different individuals, some feet being nearly parallel, others with a wide divergence. This varies at different portions of the gait. It is widest as the rear foot is first moved forward, and when the heel of the front foot is placed upon the ground.

The divergence of the feet varies according to the rapidity of the gait, and whether the gait is the erect or the forward gait, and also varies in different parts of the step. When the heel of the projecting foot strikes the ground, the foot is turned out somewhat, the degree varying in individuals. When the front of the foot is brought to the ground, the foot will be seen

to turn slightly to the inside, as the weight is thrown farther forward on the sole. It may be noticed that individuals sometimes toe-out slightly with one foot, and toe-in with the other, toeing-in being accentuated as the front of the foot is brought to the ground. Individuals who have never worn shoes walk much straighter than those the front of whose feet have been confined by shoes. The moccasin and sandal-wearing races are trained to walk using the front of the foot a great deal, and they either toe-in or walk straight; but in a leisurely gait, even among barefooted people, a certain amount of toeing-out can be seen, though this is not the case in rapid walking.

The toeing-in is partly due to the inward divergence of the first metatarsal, separating itself from the second metatarsal when the front of the foot is strongly used. This inward mobility is perhaps a vestige of earlier arboreal traits existing to a larger degree in monkeys and the anthropoid apes, where the prehensile foot is adapted to arboreal activity. It is determined in man by the shape of the articulation of the first metatarsal with the first cuneiform, as compared with that of the second cuneiform and second metatarsal, which is universal in man, and is found in the prehistoric skeleton found in the cave of the South of France

¹ Read before the American Orthopedic Association, Washington, D. C., June, 1897.

(Museum of Comparative Anatomy, Jardin des Plantes, Paris) as well as the skeleton of an African pigmy (South Kensington Museum).

An examination of photographs of bare-footed mocasin-wearing people (Turks, Dalmatians, Egyptians, Somalis, Congo negroes, Soudanese, Zulus, Dahomeys, Druses, Hindoos, Hill-country Indians, Chinese, Japanese, Javanese, natives of Australia, Patagonians, Chili-

ing-out in leisurely and erect gait is seen. In North American Indians, a slight inversion of the front of the foot is not uncommon in an active walk.

In shoe-wearing people, an angle of divergence is the rule, both in standing and walking, except in young children, where parallelism in walking and in standing is not uncommon, and perhaps normal. It is difficult to determine what degree of divergence in standing is to be regarded in shoe-wearing people as normal and what pathological. A series of observations made it clear that the angle of divergence in London (a city where a large portion of the inhabitants are of urban birth, and rarely walk actively except upon pavements) is much greater than in Holland, where the towns are small, and even the urban residents not unused to walking on rougher ground, and where, in childhood, the feet were either bare, or not compressed except by sabots, which confine the foot but little.

It would appear that the proper standing angle of divergence of shoe-wearing people is much less than is usually supposed to be the standard, regarding forty-five degrees in standing to be normal in strong-footed people, who are properly shod, and the angle of divergence in walking as much less, not greater than thirty degrees in a leisure gait, and ten degrees in a fast walk. In young children this angle is much less. In rapidly growing children, just before the age of puberty, the angle of divergence may be great, but this is to be regarded as pathological. The divergence is chiefly due to an external rotation at the hip-joint, the thigh being advanced by the psoas and iliacus muscles, which have a mechanical advantage over the internal rotators, and would turn the limb out, unless the counteracting muscles are active. This external rotation is increased, if the rear foot is used in pushing or pulling a load. I am unable to determine to what a degree there is an outward twist at the mid-tarsal joint in a normal foot. Some outward eversion of the front of the foot is not uncommon in shoe-wearing people.²

If pedestrians are watched from behind, extreme divergence of the foot will, if present, be readily seen. In a majority of cases, however, the divergence is not marked when seen from behind. The angle, however, which the sole of the foot makes (with the vertical line), as the heel is raised from the ground at the end of each step, varies with the vigor of the push and the previous divergence of the foot. If the foot has been very divergent, as the heel is raised for the final push, the heel is moved to the outside, so that the foot becomes more nearly vertical to increase the mechanical advantage of the push. Individual variations are so great, that it is difficult to form a generalization as to the normal amount of the rotation of the foot, especially as in the normal gait, or straight gait, the rotating movement of the heel is not noticeable to the eye, and usually escapes the photograph focused upon other parts of the body than the foot. In a strong,

² Pedestrians have been carefully watched in Chicago (at the World's Fair), in London, in New York and Boston, as well as in the smaller towns of Holland (Delft, Middleburg, Lieuwarden), and in England at Oxford, Cambridge and York; and the observations seem to indicate that the angle of divergence, as has already been said, was greater in London than elsewhere. But these observations were made only by inspection, though made with care. The apparent angle of divergence was noted on paper as pedestrians approached, counting those who were seen at a sufficient distance for an accurate observation, and only those who walked directly towards the observer. They were also watched from the top of an omnibus. The points in London where observations were made, were at Ludgate Circus, London Bridge, Regent Circus and Trafalgar Square. Great accuracy, however, cannot be claimed for this method of inspection.

ans, North American Indians), as well as the inspection of the gait and footprints in a camp of Somalis, Soudanese and Dahomeys, appears to warrant the generalization that the divergence, both in standing and in walking, is less in individuals where the muscles of the front of the foot have been developed by active use of the free unrestricted foot, than in a people who have worn shoes since early childhood. Many individuals of these races stand with the axes of the feet parallel, the muscles of the foot and leg being sufficiently strong to enable them to dispense with the broader base afforded by divergent feet. A slight angle of divergence (which can be roughly placed at thirty degrees) is apparently not uncommon in bare-footed adults, when standing at ease. In bare-footed young children, however, this is not the case, the parallelism of the feet appears to be the rule. In walking, parallelism of the feet is the rule in bare-footed people, old and young, though occasional toe-

rapid gait the axis of the raised sole is vertical. Individuals with hallux valgus push in a divergent angle.

The twisting of the heel and toe is best studied in extreme cases, and is very noticeable in the run of weak-legged women with a wide angle of divergence. As the rear foot is lifted from the ground, and after the final push of the front of the foot in a leisurely gait, when the muscles are relaxed, in some instances dropping of the heel to the inside is seen. This is not seen, however, in rapid gait.

If a number of individuals are watched, looking down upon them from a height, it will be noticed that the axis of the shoulder is kept, in walking, in the same plane as the axis of the pelvis, the swing of the arm giving a slight rotation forward and back of this axis. The axis of the pelvis is at right angles with the direction in which the individual is walking.

There are exceptions, however. Individuals will occasionally be seen to walk with one shoulder thrust forward of the plane of the pelvis; and in fast walking, it is sometimes seen that persons will change the axis of the pelvis in such a way as to lengthen the stride, swinging around the rear foot as the axis. This is done intentionally in fast walking, the individual rotating apparently from the neck down.

An inspection of human gait from below is not practicable, except to a limited extent, when individuals who walk across a thick glass plate are watched from below. Where this is done it will be noticed that the angle of divergence is less than would be supposed. This is due to the fact that the angle of divergence in walking apparent to the eye is that as the foot spreads in the spring forward, and not the angles of the feet in actual contact with the ground.

A more accurate observation of this contact of the sole with the ground is taken from footprints in sand, mud, dust and snow.

If a preparation of moulding clay or moist sand be made, and the individual stand upon the clay with one or both feet, and a cast be taken of the impression, an opportunity is afforded by which the amount of pressure exerted by the different portions of the foot can be judged. That portion of the foot transmitting the greatest pressure sinks the deepest. When the feet are together and the individual is standing still, without leaning forward or backwards or to the side, it will be found that the weight falls chiefly upon the heel, and the heel sinks deeper than the front of the foot in the clay. If the individual leans forward, the pressure comes upon the front of the foot, and if to either side, the foot rotates at the medio-tarsal joint, and makes greater pressure on the outer or the inner edge respectively. If a step be taken, the weight comes upon the sole, and finally upon the toes. In the step the outer edge strikes first, and then the transverse arch, heads of metatarsal, and finally the great toe itself, in a full stride. The order is as follows: the os calcis; the fifth metatarsal; heads of the fifth, fourth, third, second and first metatarsal; and, finally, the phalanges of the great toe. In normal feet, as the weight falls upon the ball of the great toe, there is a separation of the great toe from the second. This can be seen in flexible-footed people when the foot is bare, and is demonstrated in mud and clay impressions.

The footprints in mud are of value in indicating the angle of divergence in gait. They are most readily observed if the footprints are watched on an unused pathway of frozen ground, where the sun has softened

the upper surface to the depth of an inch. It will be noticed that the divergence of the feet varies considerably in gait. If a careful observation be taken, it will be seen that the angle of divergence in an individual standing should not be greater than forty-five degrees. If the individual steps from this position in a leisurely gait, the angle of divergence of the footprints will drop to thirty or twenty degrees. In a fast walk, the divergence will drop to ten or to five degrees, or even be parallel in an active walker. In a run, the foot falls to the ground with the front of the feet parallel, and in some cases there is a slight toeing in.

A similar investigation can be made on a smooth, sandy beach which the approaching waves slightly moisten. In a fast walk, it will be indicated that the

front of the foot exerts even more pressure than the heel. If a frozen beach, slightly moistened by the incoming tide, be walked upon, a curious effect can be noticed. The sand will be found too hard for deep footprints, but the pressure of the step squeezes out, and leaves the white imprints for a few seconds, as the frost is forced upwards by the pressure. It will be shown in this way that in fast walking, the front of the foot exerts more pressure than the heel, and in slow walking the reverse is seen.

Footsteps in the dust are not as instructive as those in mud or sand, for the reason that the material is lighter; but the angle of divergence can be noted in these as well as in mud impressions.

In walking in light snow which has freshly fallen to the depth of an inch, the imprints of the feet upon a hard smooth surface is indicative of the angle with which the foot approaches the ground. It will be noticed that before the imprint is reached, the snow is disturbed in an irregular line in the direction of motion. This is longer the less deep the snow, and the greater the slant by which the heel approaches the ground, provided the individual walks naturally and does not wade through deep snow. It will be seen that the axis of the footprints forms an angle with this line, indicating the amount of divergence. In the footprints in moist snow to the depth of half a foot, the turn of the front of the foot can be traced as it passes through the snow. It will be seen that the foot cuts the upper surface of the snow at a greater divergent angle out-

ward than when it strikes the ground with the final push, the toe cutting-in under the snow.

An amount of side oscillation of the trunk seen as the weight is born alternately on one leg or the other varies greatly in different individuals, some swaying a great deal, and others but little, influenced either by habit or muscular strength and weakness. This inclination may be more noticeable at the hip or at the ankle in different individuals. Variations may be seen in the rise and fall of the head in walking, as the weight is alternately thrown upon the heel, or borne upon the front of the foot, and also according to the amount of spring at the knees. The swinging of the arms also varies with individuals, and the rapidity of the gait.

No examination here is reported as to a running gait. It is, however, well known that in running, the front of the foot, and not the heel, is used; and in strong runners there is no outward divergence, though in weaker runners a certain amount is noticed.

The facts alluded to in the present paper are easily observed, but frequently forgotten. They are of value to the drill-master, suggesting the question whether or not soldiers should be trained in the forward as well as the erect gait; to the gymnastic teacher, suggesting the need of training the muscles of the front of the foot; to the physician, in seeing that the front of the foot is not crowded by the shoes. They are often overlooked by the sculptor, who neglects to depict the proper angle of divergence, either in standing or walking. This was particularly common in sculptors of the early part of this century, and may be seen in many of the statues at Westminster Abbey and at St. Paul's Cathedral. This error was never committed by the Greeks.

The proper angle of divergence is not always regarded by the drill-master. At the Guard Mount in London at St. James's Palace, a few officers were noticed walking with an angle of divergence of ninety degrees. Several privates were seen standing at rest, at an angle of divergence of over one hundred degrees; and the file leader marched at an angle of divergence of over ninety degrees. This is not ordinarily seen in marching troops, and it is probably the result of over-zeal on the part of the drill-master, in a regiment not trained for campaign, but for parade service. It would be of interest to see the effect of such a step after a twenty-mile march.

This same exaggerated angle of divergence is seen in gymnastic classes. A large angle of standing divergence, namely, ninety degrees, is taught by many gymnastic teachers. It has its value in steadying a line, affording a broad base of support, the average individual being weak-ankled. While this is beneficial for the appearance of the class, it is not beneficial to individuals, and if used in weak-ankled children it may be injurious.

The differences in gait are also not thoroughly borne in mind. In the St. Gaudens Shaw Monument the relations between the front foot and rear foot are not properly preserved, as is readily seen by a comparison with an instantaneous photograph and the groups of marching men. This was undoubtedly done, however, for artistic effect, and contributes to the sense of motion in the figures, and may be regarded as artistically correct though physiologically faulty.

Parents are frequently anxious that children should be trained to walk with an exaggerated angle of di-

vergence, under the impression that it is graceful and correct; but the fact is that footprints in a normal, active walk are parallel, and the stronger the gait the straighter the walking.

DESCRIPTION OF CUTS.

FIG. 1. Erect gait.

FIG. 2. Forward gait.

FIG. 3. Rapid gait, the front of the rear foot used in propulsion, as well as the weight of the trunk falling forward.

FIG. 4. Front view, showing angle of divergence of the rear foot.

FIG. 5. Rear view, showing angle of inclination of the raised sole of rear foot.

FIG. 6. Diagram representing gait as seen from above, with square (a) and twisting (b) shoulders.

FIG. 7. Diagram representing gait as seen from below, with the rotation of the moving foot.

FIG. 8. Diagram representing footprints from a largely divergent gait in a thin layer of fresh snow.

FIG. 9. Profile of casts of foot taken from clay impressions: (a) standing at rest; (b) pressure with the front of the rear foot at the end of the step; (c) impression of the step, with pressure at heel and toes.

ENTEROPTOSIS AS A CLINICAL FACTOR IN THE DISEASES OF WOMEN.¹

BY ARTHUR K. STONE, M.D.,

Physician to Out-Patients at the Massachusetts General Hospital, and Physician to St. Luke's Convalescent Home.

THE number of women presenting themselves at any large out-patient clinic to whom it is difficult to assign any definite diagnosis is very great. In thinking of the more than 8,000 cases, and the result of the past four summer services at the Woman's Room at the Massachusetts General Hospital, which combines general medicine together with a very large gynecological clinic, no one thing strikes me more than the comparatively small number of cases to which a distinct etiological cause can be given. Compared with the whole, the number of cases of tuberculosis, heart lesions, asthma and brouchitis, malaria, leucemia, and even the frequently occurring essential chlorosis in young women are small; and in the Gynecological Room, the cases having acute gonorrhea, tumors or lesions resulting from childbirth or abortion, which can be relieved by any single operation, as well as troublesome displacements of the womb, are few and far between compared with the number who are simply "sick inwardly."

Almost innumerable cases where constipation is the most important symptom of course present themselves. Dyspepsias of different forms are only slightly behind in point of numbers and a large proportion of the women have neurasthenic symptoms of greater or less degree.

Constipation is so prevalent that one is tempted as a time-saving operation to begin the clinic each morning by delivering a lecture to the new patients upon the care of the bowels.

Of all those who are constipated or dyspeptic, a certain number are set right by general directions, as to the care of the bowels, proper food and sufficient exercise. And also many of the neurasthenics, when talked to and the whole condition discussed, are helped by directions for a more hygienic life. In the dyspeptics, tendencies to dilatation, diminution and increase of secretions, etc., must all be considered in the diagnosis and treatment. But in spite of what you may do, there will always remain a large proportion who do not respond to simple directions, in whom con-

¹ Read before the Obstetrical Section of the Suffolk District Medical Society, April 28, 1897.

stipation or dyspeptic symptoms, or both, will continue and the neurasthenic symptoms persist without abatement.

In the region of the pelvis much the same state of things exists. Malpositions are found and some of the worse are relieved by the introduction of a pessary of almost any kind, provided it is large enough to take the place of the weakened pelvic diaphragm and form a practically solid bottom to the abdominal cavity, the patients remaining relieved even though the uterus may be left in any position, while others experience relief only if the uterus is practically in the so-called normal position. Some patients have been helped by operation and others have not been at all relieved, though having undergone many operations. The chance of seeing post-operative cases is exceptionally good at this clinic, and the number of unrelieved cases that have been operated upon is so great that one is tempted to exclaim, "What can I do to check the rapacity of the operators?" This feeling is intensified still more from the number of cases that are sent for operation, who have somehow or other received the idea from their physicians that if they have an operation, they will be well, when it only needs a superficial examination to see that an operation can either accomplish nothing at all, or be but one step in the process of cure. The rest of several weeks in bed, being often a most desirable starting-point to enable the physician to get control of the patient.

How little stress can be placed on malpositions of the uterus as an active cause of discomfort needs only continued observation on a large number of cases. Women well along in years continually report themselves at the clinic for examination in regard to sterility, presenting extreme backward displacements, who have had no discomfort during their lives or, at most, slight disturbances during the menstrual period. And their one cry of disconsolation is "I am so well: why don't I have children?" Other patients whose uterine symptoms are relieved for the time being by supports or treatment or operation, until their back, belly and thigh muscles are in good order, and their general health improved, may then go about with the *fuudus uteri* in the pelvis without discomfort. Later on, however, if they get overtired, the manifestations of discomfort instead of being referred to the pelvis may take the form of mastodynia, intercostal neuralgia or indigestion.

All this is, of course, old and is to be found in the writings of every teacher, and one must really apologize for presenting it at such length, but it is not the side that is insisted upon at the clinics, and not the idea that many students or practitioners get hold of for a long time. The enthusiasm for surgery and the consequent great number of operators at the present time tends also to increase the disproportionate value set upon the presence of single lesions as productive of symptoms. Almost any one can operate and many can operate well, but, to my mind, it is most difficult to operate judiciously, to know when an operation is needed, and when other measures will yield equally good or better results.

Having said so much in the way of preliminary observation, I want to call your attention to the condition of splanchnoptosis and to the special division of it, enteroptosis or Glénard's disease, so called from the writer, who, about 1885-7, recognizing the condition and the distinct set of symptoms accompanying the

condition, began to write upon the subject. Glénard's work has received proper recognition from some of the recent text-books, as Ewald, last edition Osler, Wood and Fitz, Da Costa and Musser all contain the essentials of the subject, but, on the other hand, neither Pepper in the "American Text-Book," nor Tyson mention the subject. Many of the clinicians devote to it a proper time in their instructions. Yet it is not dealt with for the most part so fully and carefully, nor its importance and frequency held up to the student in such a way that he appreciates that it is anything to which it is worth his while to devote his attention. Indeed, it is not at all infrequent to find a man who will talk well about gangrene of the lung, or the methods of recognizing a lesion in one sail of the tricuspid valve, or the proper nomenclature for the leucocytes, who has no idea that in general practice he will be called to diagnose between dilated stomach and enteroptosis many times, or that *ren mobilis* is more apt than otherwise to be but a part of a general condition.

A consideration of the terms used in describing the conditions involving ptosis of the abdominal viscera may not be out of place before consideration of the clinical picture. The general term, including all the varieties which will be mentioned, is splanchnoptosis, or prolapse of all abdominal viscera. Such a condition is rare, and it is quite justifiable to use it when there is prolapse of several unassociated organs, as intestines, spleen and kidney. Prolapse of single organs gives rise to the various names gastropptosis, prolapse of the stomach, hepatoptosis of the liver, nephropptosis of the kidney, splenoptosis of the spleen, metropptosis of the uterus, or prolapsus uteri, and enteroptosis, falling of the intestines, usually including with it the whole intestinal tract and sometimes used as a general word to express the whole condition, though if we hold to the Greek meaning of the words such a use is improper. The symptoms connected with intestinal prolapse are so important that the condition which I specially wish you to consider is that of enteroptosis, to which the name of the Lyons clinician first calling attention to the condition has been given, by calling it Glénard's Disease.

In enteroptosis, the intestines, both large and small, are always prolapsed, usually also the stomach and one kidney, this being the typical condition as described by Glénard; very much more rare are some of the other viscera involved in combination with the intestine.

According to my observation, however, a large number of cases are found where the intestines alone seem to be prolapsed, no movable kidney or misplaced stomach being found, but in the space between the costal borders, flatness on percussion and a pulsating aorta, while the intestines are found massed in the lower portion of the belly.

The result of the prolapse of the intestines is the destruction of equilibrium existing in the abdominal cavity and an impairment of the functional condition of the organs involved and resulting in a mechanical dyspepsia.

As the dragging of the intestine increases, both from its own weight and the pressure exerted by corsets and clothes hung from the waist, the mesenteric attachment yields, allowing of still greater displacement and drag upon the duodenum, flattening it against the vertebrae in such a manner as to hinder the pas-

sage of food from the stomach, and thus causing delay, and subsequent fermentation of the food in the stomach. The most frequent and earliest place where the intestine gives way is the unsupported right end of the transverse colon. The colon, which is in health distended, becomes collapsed unless it be filled with feces; and instead of crossing the abdominal cavity just above the level of the navel, the collapsed cord of intestine more or less M or S shaped, crosses the lower part of the abdominal cavity. The absolutely empty condition of the intestine may be made out by a rectal examination, where it is found practically impossible to introduce the finger above the ampulla of the rectum, so closely are the walls glued together. Glénard has stated that the transverse colon can be felt as a thick cord lying across the bodies of the vertebrae. This, Ewald has denied, pointing out that the mass so felt is probably the pancreas. However, this is an unessential matter, the fact being that the colon becomes collapsed, exposing a portion of the abdominal aorta which should be covered by the bowel, and either lies across the spinal column or is prolapsed so as to allow the pancreas to be palpated. The pulsating aorta is the more important symptom, and when a woman complains of a pulsating tumor in the abdomen it means enteroptosis much more often than it does aneurism of the abdominal aorta.

When the stomach is involved, as is usually the case, the lower border being found so far down often gives rise to the idea that the stomach is dilated and that the symptoms are simply due to this condition; but inflation or attempt at lavage will demonstrate that the stomach is not at all or but little dilated. Though, as has been shown, when the case is one of long standing, the twist at the pylorus brought about by the sagging pouch of the stomach and the flattening of the duodenum and consequent difficulty with which food passes through it, a dilated stomach is sure to result. Bouchard, who has been so prominent in presenting the necessity of the early recognition and treatment of dilated stomach, is inclined to resent the emphasis which Glénard has laid upon the enteroptosis, but the weight of evidence from my own observation is that in the majority of cases the prolapse is the primary condition.

Leven, who refers nearly all intra-abdominal disorders to the solar plexus, acknowledges the frequency of the intestinal displacement, but considers that the functional conditions resulting are due to the continued pressure exerted upon the solar plexus by the drag of the intestines upon the mesentery. This is interesting as offering an explanation for the results, but it is certainly not important to decide whether the functional disturbances are the result of simple mechanical conditions, or reflex in their origin from disturbances in the nerve centres. Possibly both explanations are partly true.

The causes leading to the prolapse of the internal organs are numerous, and a great deal has been written upon the subject. A few cases are probably due to congenital conditions, increased by bad hygienic measures of dress in early life. A few are distinctly traumatic, and the symptoms begin to develop from a time when there was noticed a distinct feeling as of something giving way in the abdomen, although not necessarily accompanied by any considerable pain. Lifting, picture-hanging and bicycle falls, we shall have to add, are among the most frequent causes of

this entastic form, and it has been known to occur while persons have been dancing and from attacks of vomiting. By far, however, the greatest number are of slow development, and due to relaxation of the muscular walls, occurring from any cause whatsoever. First and foremost in the case of married women is pregnancy, when the abdominal muscles become so stretched that they no longer give any support to the intestines. In unmarried persons there is usually a combination of causes whose resultant is the enteroptosis. Indeed it is very hard often to say what is the cause and what the effect so intimately are they related to each other. Anything which tends to weaken the abdominal muscles and the internal attachments makes the condition possible. Examples of this are tubercular, chlorotic conditions or a weakened state, induced by typhoid or other acute infections and also the result of improper food and overwork. Such conditions are further intensified by unhygienic dress and lack of exercise.

Because less is heard at present about livers cut in two as the result of tight lacing, and because the wasp waist is no longer fashionable, and as so much is written about lacing, most of us are possessed of the idea that women of the present time do not lace. Some of us also remember Rosina Vokes and her singing "But 'is 'eart was true to Poll," which required the most violent gymnastic dancing, and at the same time the dancer was dressed with a long court train and a perfect fitting waist which distinctly showed that the fit depended on the corsets beneath; and we have said to ourselves, "If the modern corsets allow of such free movements, then surely they do no harm." But if the present corset is not drawn so tightly as to interfere with the breathing, there is a constant temptation to keep the waist small, and so enough pressure is exerted to press upon the belly and spinal muscles to such an extent that they are much weakened and relaxed. The pressure too is all exerted in the wrong direction, and the abdominal contents are forced down towards the pelvis. The majority of women also hang their skirts by bands about their waists, and thus add to the pressure in the wrong direction.

Overeating and consequent infiltration of the abdominal walls with fat is another cause which may lead to the relaxation of the walls whose tone is so necessary to the maintenance of the proper position of the intestines.

Subjective neurasthenic symptoms almost always develop sooner or later and add much to the difficulty both of making the diagnosis and having the proper treatment carried out.

The diagnosis in the cases that are not advanced is often difficult, and practically comes down to making an empirical test of the means used for the relief of the condition. The points to note in making any full examination are, first, the condition of the abdominal walls as to laxity. And right here one is frequently led into serious error, for at any examination many patients are so frightened or embarrassed that the recti are found so firmly contracted that you are tempted to take it for granted that the belly walls are in good shape, when in reality they possess little supporting power. Pulsation of the aorta, which is not normally felt on light palpation, should direct the attention of the physician to the possibility of the enteroptosis being an important factor in the condition. (Let me add an aside here that one of the first symp-

toms which attracted my attention in the study of my cases was, that a woman with a pulsating aorta was practically always neurasthenic. The converse of this statement, however, is not true.) If there are lax abdominal walls and a pulsating aorta, the outlines of the stomach should be determined, even inflating it if necessary, and the pancreas palpated. Next the condition of the kidneys should be examined in order to determine whether they are movable, always remembering that in floating kidney the right is the more liable to be free. In my experience it is rare to find cases of *ren mobilis*, accompanied by symptoms which are dependent solely upon the malposition of the kidney. Many movable kidneys give rise to no especial symptoms of discomfort. A considerable number form a part in the condition that we are considering, and in a very few cases the symptoms are referable to the displacement of the organ alone. This accounts for the frequency of successful operations not giving the relief expected.

On the pelvic examination, the laxity of the pelvic floor is often of as much or more importance to determine as to the exact position of the uterus and ovaries; while the collapsed rectum, partly filled with nubs of inspissated feces, lends completeness to the picture.

Dyspepsia, constipation, tired and dragging sensations are the symptoms most complained of. In many cases the patient will be found to be anemic, and in the majority of cases more or less neurasthenic.

Glénard has stated that a valuable diagnostic sign is to be found by standing behind a patient and holding the thumbs firmly against the sacrum, while the under part of the hands are pressed as deeply as possible behind the symphysis and ilium, and if by thus supporting the intestines the patient experiences a sense of relief from the dragging sensations, it may be concluded that the case will be relieved by appropriate treatment for enteroptosis. Too much dependence, however, cannot be placed upon this procedure, either from a positive or negative standpoint.

Treatment for enteroptosis consists in the first place, of an attempt to hold the prolapsed organs in their normal position by means of an abdominal band which shall counteract the downward pressure of the clothes and take the place of the relaxed abdominal walls.

Next, proper exercise should be introduced in order to restore, so far as is possible, the abdominal muscles to their normal condition so that the abdominal support shall be discontinued as soon as possible.

Secondary treatment is just as important and is directed to counteracting the other prominent symptoms, as dyspepsia, constipation and general debility. Pelvic symptoms are by no means to be neglected and care must be taken that the abdominal support does not aggravate the symptoms caused by moderate uterine displacements. Operation, in many cases, will add to the efficiency of the treatment. The kidney may give trouble even to the point of requiring suture or if hydronephrosis has developed, removal. The physician must try to bring himself to look upon the condition as extensive and requiring attention, to minor details in a number of organs apparently remote.

The best and simplest form of bandage for the majority of cases I have not settled as yet to my own satisfaction. Neither have I determined what is the best course of gymnastics to follow. A bandage with a certain amount of elasticity in it is probably the best.

Also, I think that there must be some sort of a perineal support to hold it in place.

To sum up the results of my observation and reading, I would say that though enteroptosis may exist without giving rise to any noteworthy symptoms, there are a large number of conditions marked by dyspepsia, constipation and pelvic disorders, into which it enters and consequently this is to be borne in mind in all cases not yielding to the ordinary treatment of diet and hygiene.

MOVABLE KIDNEY AND ENTEROPTOSIS.¹

BY F. B. LUND, M.D.,

Surgeon to Out-Patients, Boston City Hospital; Assistant in Anatomy, Harvard Medical School.

ONE of the results of the erect position in man, which has been adduced as the cause of so many ills from which he alone of the vertebrates is the sufferer, is that the larger solid viscera, namely, the liver, spleen and kidneys, are brought into the upper part of the abdominal cavity, where their weight is supported in part by the ligaments of connective tissue and peritoneum which hold them to the diaphragm and abdominal walls, and partly by the hollow viscera (intestines) below them, which supported by the abdominal walls, and filled with gas and semi-solid contents, form a kind of elastic cushion, upon which a large part of their weight is borne. Any relaxation of the pressure of the abdominal walls will necessarily decrease the pressure upon the intestines lying underneath these organs, and cause greater strain to be thrown upon the peritoneal and other supports of these organs. The stomach and intestines, especially if filled with solid or fluid material, will, unless supported by the elastic pressure of a normally tense abdominal wall, tend to drag down and stretch their supports; and we can easily imagine that such a condition of things might tend to cause a gradual stretching of the peritoneal ligaments, and a descent of the viscera to an abnormally low position in the abdominal cavity.

Observations of the pressure in the upper and lower portions of the abdomen, as recorded by a manometer bulb introduced into the stomach and rectum, show in an interesting manner the amount of the actual pressure exerted upon the viscera in the lower portion of the abdominal cavity by those situated in the upper portion. The pressure in the stomach, as measured by a manometer² in the upright position of the body, has been found to be 11 cm. of water, and in the rectum 39 cm. The pressure in the stomach, which has no overlying viscera to impinge upon it, represents the elastic pressure of the abdominal walls; that in the rectum this pressure *plus* the amount of the weight of the viscera which was not borne by their ligaments, which amounts therefore to $39 - 11 = 28$ cm. of water.

When the subject was placed on an inclined plane at an angle of 50° , with the head downward, the manometer in the rectum measured 11 cm. of water, and that in the stomach 27 cm., thus showing that 11 cm. of water might be taken as a fair index of the intra-abdominal pressure, in so far as due to the tension of the abdominal walls, when a man is standing quietly at rest. The constant variation in abdominal pressure when the body is in active motion is shown

¹ Read before the Boston Society for Medical Improvement, April 26, 1897.

² Schwerdt: Deutsche Med. Woch., 1896, Nos. 4-6.

by the fact that holding a weight of 10 kilogrammes out at arm's length increased the pressure in the stomach to 59 cm., and in the rectum to 78 cm. Strong voluntary contraction of the abdominal muscles caused a pressure in the stomach of 66 cm., and in the rectum of 84 cm. These figures are sufficient to show the great variations of abdominal pressure under normal conditions, and the constant variations in the strain to which the supporting ligaments of the viscera are subjected. When the intra-abdominal pressure is greatest, the tension in the ligaments will be least, and *vice versa*. There is doubtless a compensatory mechanism by which intra-abdominal pressure is kept most of the time at about normal. When the pressure of the abdominal walls relaxes, the blood flows more rapidly into the vessels contained in the abdomen,

FIG. 1. Drawing from Dissecting-room Subject. Female. Laced thorax, ptosis of colon and stomach. Double movable kidney.

and the veins are emptied more slowly, so that blood is, as it were, sucked in and brings the pressure more nearly to normal. But the regulation of the pressure by this mechanism takes time, and cannot follow instantly upon the sudden contractions and relaxations of the abdominal walls, so that these sudden movements may throw at least a temporary strain upon the ligaments.

The contractions of the diaphragm and abdominal muscles in respiration cause a certain variation in pressure; the filling and emptying of the intestinal canal with gas and feces is another cause of variation, and the changes in the blood-supply of the abdominal organs another. There can be no doubt that by emptying the bowel by free catharsis intra-abdominal pressure is lowered, as is shown by the failure of the bowel to protrude when a laparotomy incision is made on a patient properly prepared for operation. The collapsed bowels lie quietly in the cavity, and the surgeon has no trouble from the protrusion of distended

coils; whereas, in operating on patients whose bowels contain the normal amount of food and flatus, the opposite conditions prevail, and the bowels are forced out in such a manner that there is often great difficulty in replacing them.

A permanent condition of emptiness of the bowel, such as is caused by a low diet or a chronic diarrhea, will therefore tend to cause a decrease of intra-abdominal pressure. Relaxation of the abdominal wall from overstretching, as from repeated pregnancies, will certainly decrease intra-abdominal pressure, since the outstretched muscles may never regain their normal power of contraction, and a condition even of pendulous belly, the *Hängebauch* of the Germans, may result. Relaxation of the perineal supports from rupture attended with uterine prolapse, etc., will also tend in marked degree to lessen intra-abdominal pressure.

The large amounts of adipose tissue, subperitoneal, omental, etc., which often in fat persons so distends the abdominal cavity, and fills in the interspaces between the organs, may be absorbed under the influence of wasting disease, so that a marked decrease in intra-abdominal pressure may result.

Now, to the influence of a diminution of pressure tending to stretching of the supporting ligaments of the viscera, there may be added a pressure calculated to directly displace the viscera downward. I refer to the effects of tight lacing, which, by crowding the viscera, especially the stomach when distended with food, into the lower portion of the abdomen, may stretch the supporting ligaments, and cause a definite ptosis of the stomach and transverse colon, which is dependent from its greater curvature (see figure). Not only the stomach may be caused to descend, but the right kidney may be actually caught between the liver and the posterior abdominal wall, by the pressure of the thorax, and squeezed downward and out below the ribs, a condition actually present in the case represented in Fig. 1, which is a drawing from a subject in the dissecting-room of the Harvard Medical School. The right kidney lay in the false pelvis, and could be easily moved upwards into its place, a distance of $3\frac{1}{2}$ inches. The chest showed in a marked degree the narrowing of the lower outlet by lacing, as will be seen from the figure. When the kidney was pushed back into place it remained there, but placing the body in the erect position, or very slight lateral pressure upon the thoracic walls with the hands, immediately forced it downward into the false pelvis. The accompanying ptosis of the stomach, which was flat and entirely empty when the drawing was made, may be seen in the figure.

Of all the abdominal organs which may descend to lower positions than normal in obedience to the law of gravitation or of external pressure upon insufficient supports, the kidneys have attracted most attention. The kidneys are not held in place by ligaments, but by connective tissue, covered in front by a layer of parietal peritoneum. They are usually surrounded by a layer of fat, the absorption of which from wasting diseases cannot fail to leave them loose in their retroperitoneal pockets. The right kidney has in front of it the right lobe of the liver, and the peritoneum on its anterior surface is reflected upward to form the ascending and beginning of the transverse mesocolon and running along its internal border is the descending portion of the duodenum. The left kidney has in

front of it the descending colon with its splenic flexure, which is attached more tightly and higher up than the hepatic, so that the relations are less complicated and the liability to loosening of supports is less.

If now the peritoneal covering of the right kidney be loosened, from absorption of fat or other cause, it is apparent that the traction of a colon and hepatic flexure filled with feces might drag upon and loosen it still further, allowing the kidney to descend into the false pelvis. In descending, the kidney will move in the arc of a circle of which the junction of the right renal artery with the aorta is the centre. The kidney will move downward with the relaxed peritoneum, and will also glide underneath it. The renal artery is usually lengthened by the dragging down of the kidney upon it.

When the kidneys lie loosely in their capsule, any increase of abdominal pressure may cause them to descend, such as coughing, straining at stool, lifting, and the like, and any jolt or jar from an external cause may have the same effect.

Relaxation of the abdominal walls and perineal supports, due to conditions associated with pregnancy and the puerperal state, renders women peculiarly liable to ptosis of the viscera; so that movable kidney is, as one would naturally expect, much commoner in women.

As to the actual frequency of the disease itself, we have no accurate data, and of such data as we have the clinical vary greatly from the pathological. Skorzewsky found that 32 females out of 1,030, and 3 out of 392 males, suffered from movable kidney, while in a table given by Newman⁸ movable kidney is shown to have been recorded only 11 times in 11,258 autopsies. Several reasons may be adduced to account for this, one of which is that patients rarely die of the disease, and another, that with the body in the horizontal position the kidneys return to their normal situation, and unless the pathologist examines with the idea of seeing whether the kidneys glide under the peritoneum, he may not note the fact of their mobility. Newman's examinations in the inspection room of the Glasgow Royal Infirmary, gave a percentage of 1.8 cases in which the kidneys were movable through an area of over three inches.

Mobility of the spleen is very much rarer than movable kidney, and seldom comes under the observation even of experienced clinicians. When it exists, however, the loose attachments of this organ allow it to move about much more freely than does a movable kidney. Its mobility is also usually associated with dilatation of the stomach and ptosis of other viscera. Splenectomy for wandering spleen has been performed 12 times without a death, and Rydygier has devised an ingenious operation for splenopexy.

Mobility of the liver is very rare indeed, a fact which is probably due to the intimate connection between the liver and the diaphragm by the coronary ligaments. A stretching of these ligaments, particularly of the right, and of the falciform, when dragged on by the weight of the right lobe in conditions of lowered intra-abdominal pressure, does however take place, allowing the liver to descend, rotate to the right, and move about much more freely than normal.

Mobility of the liver, spleen and kidneys, with ptosis of all the viscera, is a condition rarely observed at autopsies; and the observation of a case of this condition in the dissecting-room of the Harvard Medical

School first attracted my attention to the subject. During the winter of 1896-97 I have examined in the dissecting-room 46 adult subjects (37 males and nine females), and in five subjects (three males and two females), I have found one or both kidneys movable, so that when the bodies were inclined at a very moderate angle with the horizontal (about 20 degrees), they descended so that their lower ends reached the crest of the ilium. It is not fair to say that such mobility is what one would naturally find from the emaciation due to death from wasting disease, for a large proportion of subjects in the dissecting-room are emaciated, and in most of them the kidneys are firmly in position, showing that in those in which the kidney was found movable, the condition must have been present during life.

FIG. 2. Dissecting-room Subject. Female, age eighty-three years. Ptosis and dilatation of stomach. Ptosis of colon and liver. Movable spleen and double movable kidney not shown in cut. Lower border of stomach reaches level of pubes.

In one of these subjects, that of a woman, the following interesting condition of relaxation of the abdominal supports was present, a partial idea of which may be obtained from Fig. 2. Suffice it to say, in the way of description, that the right kidney lay in the right iliac fossa, and was easily movable upward three and one-half inches into its normal position, and over to the median line. The position of the stomach and liver is interesting: the lower border of the liver is seen to lie in the iliac fossa at the level of the anterior superior spine of the ilium, and the stomach is seen to be enormously dilated, and elongated (ptosis) so that the greater curvature reaches the pubes, and the vertical lesser curvature the umbilicus. The hepatic flexure of the colon, very loosely attached, lies in the right iliac fossa, and the transverse colon itself lies in the bottom of the pelvis, and when brought outside

⁸ *Surgical Diseases of the Kidney*, p. 20.

the abdomen crosses the thighs four or five inches below the pubes. The spleen lies so that its lower border is two inches below the thoracic wall, and it could easily be drawn entirely outside the thorax, and moved freely about. The falciform ligament of the liver is very wide, and the coronary ligaments were slightly stretched, so that the liver fell away from the diaphragm more than normal and was rather freely movable. The abdomen of this woman, which was flaccid though not pendulous, showed lineæ albicantes. The pelvic organs were normal except for the atrophy due to her years, and the pelvic supports were in normal condition.

This striking instance of the association of movable kidney with general relaxation of the supporting ligaments of the viscera suggested several interesting questions: whether movable kidney was not often only one manifestation of a general relaxation of peritoneal supports, with ptosis of the stomach and other viscera; how far the symptoms, on the part of the kidneys, gastro-intestinal tract and nervous system, might be due, not to movable kidney alone, but to the accompanying ptosis of the other viscera; and how far these symptoms would be relieved by the commonly performed operation of nephrorrhaphy for movable kidney, and how much benefit might be expected from abdominal supports, bandages, etc.

The earlier writers on movable kidney noted the frequent coincidence of movable right kidney with dilatation of the stomach and gastro-intestinal catarrh, and Landau explained this by the dragging and kinking of the limbs of the duodenum by the descent of the right kidney carrying with it its peritoneal covering. This kinking, he thought, obstructed the outflow of the stomach contents and accounted for the gastric dilatation. No satisfactory description, however, of the disease enteroptosis was given until 1885, when Glénard, a physician practising at Lyons and Vichy, published in the *Lyon Médicale* his monograph entitled "Application de la Méthode Naturelle à l'Analyse de la Dyspepsie Nerveuse—Détermination d'une Espèce." His views were at first received with suspicion, but in a year or two his work received the sanction of the French Academy of Medicine; such leaders in French medical thought as Dujardin-Beaumetz, Hayem and others accepted his results in whole or in part, and Glénard's disease, or enteroptosis, took its place in medical literature. In 1890, Ewald and Kuttner made a careful study of the relation of movable kidney to enteroptosis, and since that time enteroptosis has, as a disease, been more accurately understood.

To Glénard, although his conception of the etiology and his remarkably dogmatic and detailed account of the symptoms and physical signs have not entirely stood the test of time, belongs the credit of having recognized the disease and established it as a clinical entity.

Glénard argued that a large class of the cases which were classed as nervous dyspepsia, or dyspepsia without known cause, attended by general neurasthenic symptoms, were due to a definite and easily appreciable condition of the abdominal organs, namely, ptosis with relaxation of the ligaments. He distinguished as due to this cause those dyspepsias classed as the intestinal, rather than the purely gastric type, namely, those in which the symptoms came on some time after eating, and were somewhat as follows: anorexia, or false feeling of hunger, a feeling of fulness in the epigastric

region, pyrosis, sour taste or dryness of the mouth, burning or dragging pain in the upper part of the abdomen after eating, etc. The intestinal symptom was constipation, often interrupted by attacks of diarrhea; the constipation often very obstinate, so that very hard dry scybala were passed, and often, as a result of cathartics or enemata, large pieces of membrane appeared in the stools, giving a true membranous enteritis. There was frequent putrefaction of the intestinal contents with distention of the abdomen and the passage of much fetid flatus. The general symptoms were weakness, irritability, headache, cold hands and feet, palpitation, sleeplessness, and so on through the whole neurasthenic catalogue. Loss of weight, sallowness of the skin, and often loss of the hair followed in due course; and the patient might come ultimately to look like a victim of cancer. The various common methods of treatment—massage, electricity, baths, etc.—proved of no avail.

As physical signs, Glénard found palpable pulsation of the abdominal aorta in the epigastric region and a transverse cord which he took to be the prolapsed and contracted hepatic flexure and transverse colon to be felt running from the lower right to the upper left lumbar region. The prolapse began, according to his theory, with a descent of the hepatic flexure and first part of the transverse colon, which are loosely attached by mesentery to the front of the right kidney, and were dragged down by the weight of the fecal contents accumulated there by reason of constipation. This prolapse resulted in a sharp angle at the splenic flexure, with interruption of the fecal current, and consequent further accumulation of contents and dragging down. The weight of the colon dragged upon the greater curvature of the stomach, especially the pyloric portion, and caused obstruction at the first flexure of the duodenum, and gastric dilatation as well as ptosis. Finally, there was stretching of the entire mesentery of the small intestine, dragging down of the liver by the gastro-hepatic ligament, and ptosis of the kidneys, due to sagging and loosening of their peritoneal coverings, or, in other words, a prolapse of all the abdominal viscera. Glénard believed that nephroptosis was always a part of a general enteroptosis, or, in other words, that movable kidney without enteroptosis never existed. The general intra-abdominal pressure is diminished in enteroptosis, because the intestines do not contain the normal amount of gas and feces, and as they hang down in their empty condition, simply drag on their supporting ligaments without properly filling the abdomen and supporting each other.

Out of 1,310 cases of disease of the gastro-intestinal tract, Glénard made the diagnosis of enteroptosis in 404 cases. Ewald calls attention to the fact that in the entire literature of the subject there were only three or four autopsies in which this condition was found. Glénard, however, rests his diagnosis finally on what he calls *l'épreuve du sangle*, that is, the relief which he found was given his patients by the application of an abdominal support, and the fitting of such a support he regarded as the first and fundamental step in the treatment of these cases.

Ewald, in the paper referred to in 1890, affirmed the existence of enteroptosis as a definite disease, first recognized by Glénard, but disputed the value of certain of his symptoms. The *corde colique transverse* alluded to above, and so definitely described by Glénard as the prolapsed and contracted transverse colon, Ewald

holds to be nothing more or less than the pancreas, which in cases of gastro-ptosis can be felt as a transverse ridge above the descended lower curvature of the stomach. Ewald held that the only way to definitely recognize enteroptosis by physical signs was to blow up the stomach with gas, preferably by means of the stomach-tube, and mark out its outlines by percussion upon the abdominal wall. If the greater curvature reached to or below the umbilicus, in the absence of known cause for dilatation, we have gastro-ptosis; and distention of the colon with gas by the rectal tube may establish the low position of the transverse colon. If now we can establish by palpation a movable right kidney, we have a definite diagnosis of general ptosis of the viscera.

The occurrence of obstruction of the intestine from kinking at the flexures, due to the acute angles formed by the descending loops, Ewald denied, and held to the view that the functional disturbance of the stomach and intestines and of the general nervous system in this disease was due to the stretching of the ligaments with the sensitive filaments and plexuses of the sympathetic nervous system therein contained. He admitted, however, that dragging down of the stomach by the prolapsed colon might cause obstruction of the outflow of gastric contents and consequent dilatation, due to the sharp angle produced between the movable first part and the fixed second part of the duodenum.

Ewald found that the extreme condition of enteroptosis, in which the liver and spleen were dragged down and movable, as in the case shown in Fig. 2, were very infrequent. The infrequency of mobile liver is undoubtedly due to the anatomical causes alluded to earlier in this paper.

The majority of the cases of enteroptosis coming under his experience were not the subjects of typical abdomen pendens, which we sometimes see in old women as a result of repeated pregnancies, but of a relaxed though not actually pendulous condition of the abdominal walls. Ewald and other later observers have found movable kidney and enteroptosis perhaps as frequent in women who have not borne children as in multiparæ; and Meinert has established a definite relation between movable kidney with enteroptosis in young girls and compression of the thorax by tight lacing.

Of especial interest in connection with the subject of this paper, the relation between movable kidney and enteroptosis, are the observations of Ewald and Kuttner on 100 cases of movable kidney observed by them at the Augusta Hospital in Berlin during eight months. In 89 of these 100 cases they were able to distend the stomach with air, and in 79 of these they found the greater curvature of the stomach three or four centimetres below the umbilicus, or at a still lower level. The cases comprised 47 of right movable kidney, 25 in whom both kidneys were movable, and 7 in which the left alone was prolapsed.

The symptoms of these cases were not those of gastric dilatation, but chiefly of the kind usually described as nervous dyspepsia. In only 15 of these 79 cases, however, were they able to diagnose by the low position of the lesser curvature an actual ptosis, so that Ewald was unable to subscribe to the opinion of Glenard, that movable kidney is always a part of a general enteroptosis. The fact, however, that in only 10 of these 89 cases the greater curvature of the stomach was in the normal position, shows that in nearly 90

per cent. of the cases either beginning dilatation or ptosis of the stomach was present.

The absolute frequency of enteroptosis, or as Ewald calls it, splanchnoptosis, will probably never be accurately determined, for the reason that the necessary physical examination is generally not carried out in patients who complain of the symptoms of nervous dyspepsia. A marked degree of enteroptosis may exist without much effect on the general health, as shown by the fact that the case shown in Fig. 2, as I was able to ascertain, was not thought to have much the matter with her during life and lived to the age of eighty-three years. In the majority of cases in which the condition is at all marked, it is probable that the subjects of it will consult physicians for dyspepsia or neurasthenia. The fact that enteroptosis

FIG. 3. Enteroptosis. Female, age forty. Greater curvature of distended stomach at level of pubes. Lesser curvature below umbilicus. Percussion outlines shown in continuous lines. Dotted line shows position of right kidney, which was more freely movable than left.

is more frequent in patients with thin, relaxed abdomens than with the typical pendulous belly, is brought out by the fact that in Ewald and Kuttner's 15 cases only two presented the typical abdomen pendens.

From these investigations we are able to diminish the class of functional nervous dyspepsias by subtracting a class of cases in which we find general relaxation of the abdominal ligaments with stretching and pulling upon the nerve filaments going to the intestine, and consequent secretory or motor derangement of the same. A symptom in some degree peculiar to these cases which clinical observation has brought out in the last five years is the passage from the bowels, during the attacks of diarrhea which characterize them, of shreds of membrane—a membranous enteritis. These severe recurrent attacks of enteritis have been a marked symptom in all the cases which have come under my observation. The case shown in Fig. 3, which was a beautiful case of double movable kid-

ney, with dilatation and marked ptosis of the stomach, which entered the Boston City Hospital in the service of Dr. Withington, who kindly allowed me to blow up the stomach and have her photographed, entered the hospital for an acute attack of enteritis. The position of the right kidney and of the greater or lesser curvature of the stomach are shown in the photograph. The lesser curvature lay at the level of the umbilicus and the greater hung down to the pubes. The woman from whom the drawing of Fig. 2 was made died during an acute attack of diarrhea, and in two other cases which I have seen this diarrhea was the symptom for which they came under the physician's treatment.

A very important etiological factor in the production of enteroptosis, which has been alluded to but not given the prominence it deserves, at the beginning of

FIG. 4. Enteroptosis (from Meinert), showing dilated stomach, prolapsed colon and right kidney. Laced thorax.

this paper, is the effect of tight lacing on young girls. Meinert, of Dresden,⁴ in 1894, published a paper in which he ascribed almost all cases of chlorosis in young girls to enteroptosis, and the enteroptosis to the effects of tight lacing. In the former contention he has not been generally upheld by subsequent observers, in the latter he has. He publishes a large number of excellent photographs of young women, showing the coexistence of "Schnürrhorax" gastropnoia, and mobility of the kidney. His method of distending the stomach for the purpose of marking out its percussive outline is the administration of bicarbonate of soda and tartaric acid in separate powders. Subsequent writers⁵ have advocated the use of the gastro-diaphane in the diagnosis of this condition.

⁴ Zur Etiologie der Chlorose, Wiesbaden, 1894.

⁵ Einhorn: Enteroptosis, Medical News, September 12, 1896.

The crowding down of the stomach by lacing has been demonstrated by Dickinson⁶ and by Wenke.⁷

The accompanying photograph from Meinert (Fig. 4), may be compared with Fig. 1. It must be remembered that the sketch was taken with the stomach absolutely empty and the subject on the back. With the stomach full and the body in the erect position, the prolapse would undoubtedly have been much more marked.

There can be no question that in tight lacing there is brought to bear a strong force tending to the displacement downward of the stomach, small intestines and right kidney, and to an outstretching of their peritoneal supports. The liver may be either driven upward or downward, elongated, deformed, or nearly cut in two by these same forces, according to the level at which the constricting force is applied. Whatever result it may produce, the fashion receives no support from the basis of either clinical or pathologico-anatomical study.

Other causes of enteroptosis which might be classed as internal or local causes, in contradistinction to general causes, such as laxness of the abdominal walls and the like, have been recorded. The case of Treves⁸ is an instance in point. He had to treat a case presenting abdominal and gastro-intestinal symptoms, worse on movement and in the erect position, in a young woman of twenty-two, whose symptoms had begun six years before with an attack of acute abdominal disturbance. The patient was only comfortable when lying down. The right kidney had been found to be movable, and been sewn in position three years before. Every form of dietetic and hygienic treatment had been tried, and numerous health resorts visited. A heavy and complicated abdominal support had to be worn. The liver was found to descend two inches in the erect position, and the stomach and whole mass of intestines appeared to fall downward. Owing to the pitiable condition of the patient, who was bedridden, and whose condition was really serious, Treves performed a median laparotomy, and found the liver low down and freely movable. On attempting to get a good look at the stomach he found that it was impossible to get it up into the wound. On looking for the cause of this condition, he found the great omentum rolled into a hard, rigid cord, attached to a mass of stony hardness in the right iliac region. This mass, which was found to consist of calcified tuberculous mesenteric glands, was enucleated through a second incision. The omentum was now cut away, and the stomach was then found to be freely movable. The spleen was very mobile, and the transverse colon lay below the umbilicus. The operator sutured the liver up against the parietes close to the xiphoid cartilage, passing his sutures through the round and falciform ligaments, and the patient was restored to health.

I will call attention to one more dissecting-room observation, Fig. 5, which irresistibly suggests a local cause of enteroptosis. The subject was a middle-aged male, with marked ptosis and dilatation of the stomach, the lesser curvature of which was vertical, while the greater curvature lay half-way between the umbilicus and the pubes. The lower border of the right lobe of the liver lay in the iliac fossa, and the liver was movable and rotated to the left. The right kidney lay

⁸ British Medical Journal, January 1, 1896.

entirely without the lower border of the thorax and could be easily pushed up into place. The cecum was long, and had a mesentery; it was very freely movable and hung down so as to rest on the bottom of the pelvis. The gall-bladder contained gall-stones; and there were strong adhesions binding the lower surface of the right lobe of the liver, the hepatic flexure of the colon, the gall-bladder and the first flexure of the duodenum together. The dilated and movable cecum and the ascending colon were filled with feces. The presence of the firm adhesions of the liver to the hepatic flexure, evidently due to the inflammation around the gall-bladder, caused by the presence of the stones, irresistibly suggested, that after these adhesions had been produced the weight of the cecum and ascending colon with its contents had dragged down the liver and hepatic flexure, loosened the peritoneum over the front of the kidney, and allowed the latter to descend. As seen in the figure, when lifted out of the abdomen, the cecum hung down well below the pubes. The history of this man was unfortunately not obtained.

An extended consideration of the treatment of enteroptosis is not within the scope of this paper. Suffice it to say that it consists chiefly in supporting the viscera, increasing the abdominal pressure by the application of suitable abdominal supports, and by exercises to increase the strength of the abdominal walls; in the treatment of the gastro-intestinal symptoms by careful regulation of the diet, etc.; and, finally, in a course of rest, massage and exercises to combat the neurasthenia, and improve the general condition. As a first measure to increase the abdominal pressure, I have found an elastic abdominal bandage to give marked relief.

A more general realization of the importance of enteroptosis as a factor in many conditions which are presented to physicians for treatment may, it seems fair to expect, lead to certain not unimportant results.

First, a rational system of therapeutics may be more generally applied to a large class of cases of "nervous dyspepsia."

Second, the same treatment will probably relieve a large number of patients who are subjected to local gynecological treatment, with the view of benefiting general and gastro-intestinal symptoms supposed to be "reflex" to various local troubles.

Third, a more rational means of prognosis in cases of movable kidney, and of decision as to mechanical or operative treatment may be possible. For instance, in the very large class of cases where movable kidney is complicated with enteroptosis, although by suturing the kidney in position we may relieve the symptoms due to torsion of the renal vessels or ureter, and the like, we will probably find, as we all know from our own experience to be sometimes the case, that the general neurasthenic and gastro-intestinal symptoms may not be benefited by the operation. It is hardly fair to expect that suturing the kidney in position will cure dilatation of the stomach or ptosis of the other viscera. The propriety of following a nephrorraphy by measures calculated to increase and maintain increased abdominal pressure can hardly be questioned. Cases of movable kidney which are found on examination to be uncomplicated by enteroptosis, will naturally stand more chance of benefit from nephrorraphy.

Nephrorraphy, then, will relieve such symptoms as arise directly from the descent of the kidneys, and are due to torsion of the renal vein or twisting of the ureter, but it cannot be expected to cure the symptoms

due to ptosis of the stomach and other viscera. I do not mean to imply that nephrorraphy is not indicated in cases where nephroptosis is associated with enteroptosis, as I believe the fixation of the kidneys if freely movable and causing symptoms, to be one of the most important steps in the treatment of these cases, but that such an operation must be both preceded and followed by treatment of the general condition.

Although we have no absolute data of the proportion of cases of movable kidney which are complicated with enteroptosis, the observations which I have made, although few in number have led me to the belief that ptosis of the kidneys is almost always associated with more or less ptosis of the other abdominal viscera, and that slipping down of the kidney behind the peritoneum, without more or less general relaxation of the

FIG. 5. Drawing from Dissecting-room Subject, Male. Ptosis of colon and ptosis with dilatation of stomach. Adhesions of hepatic flexure to liver and gall-bladder. Movable right kidney.

latter, and of the supporting ligaments of the viscera, is the exception rather than the rule.

Careful attention to the subject in post-mortem rooms can alone determine the absolute frequency of relation of enteroptosis to movable kidney, and I cannot help thinking that attention to the subject will show that the condition is more frequent than has been heretofore believed.

It is probable, also, that a routine physical examination for mobility of the kidneys and dilatation of the stomach in medical and gynecological clinics will disclose a more frequent occurrence of this condition than we have heretofore suspected, and will greatly aid us to a rational and efficient treatment of many obscure and hitherto unexplained cases.

ACUTE TUBERCULOSIS IN PUERPERAL WOMEN.¹

BY EMMA L. CALL, M.D., BOSTON.

THE various forms of septic infection play so large a part in the pathology of the puerperium that the influence of the puerperal state upon other diseases has hardly received the attention it deserves. It is true that for a long time it has been known that the zymotic diseases present peculiar symptoms in their course and development during this condition, but outside of these very little seems to have been recorded.

The effect of pregnancy and parturition upon cases of established tuberculosis has been much discussed, and equally good authorities are not agreed upon the subject, but the development of tuberculosis during the puerperium in patients who had no previous history or appearance of the disease is a subject upon which I can find very little information, and I have therefore ventured to think that the following cases are of sufficient interest to justify me in bringing them before this Society.

CASE I. Mrs. M., age twenty-seven, was delivered of her second child in the New England Hospital Maternity, April 12, 1896. The patient is slight and delicate looking. Her condition during pregnancy had not been good. She suffered much from indigestion, for which she was treated in the medical wards of the hospital in March.

Her first labor was tedious. Breech presentation. Child still-born.

The second labor, also a breech, was equally slow; delivery manual. The child proved to be an acephalous monster. Moderate laceration of the perineum, immediate suture.

During the first nine days after labor the patient was nervous and apprehensive; but the temperature was practically normal, reaching her highest temperature, 99.5°, at night a few times. On the tenth day the temperature rose suddenly to 104°.

Upon examination the perineum was found to be well united. Lochia normal. Nothing noticeable in pelvic organs except a slight sensitiveness in the ovarian region.

From April 22d to May 1st the average morning temperature was from 99° to 100°, the maximum (sometimes at noon, sometimes at 5 p. m.) ranged from 101° to 103°. She was removed to the medical wards of the hospital the 1st of May. At this time she felt fairly well, had neither chills nor sweats, and no apparent consciousness of fever. Her only tangible discomfort was a tendency to intestinal indigestion. Her appetite was fair. She lost flesh steadily, but not very rapidly.

An examination made at this time is recorded. Heart and lungs normal. Abdomen apparently normal; no dullness, distention nor sensitiveness in any part.

Pelvic examination: uterus in good position, involution fairly well advanced. No sensitiveness anywhere. The uterus, however, was not freely movable, and there was an ill-defined thickening in the region of the appendages, though no distinct mass could be felt.

Examination of blood: hemaglobin 60 percent. Red corpuscles much diminished. Marked leucocytosis. No plasmodia.

Her general condition and temperature remained about the same during May. She was able to be up and to sit out of doors on pleasant days, and was usually very cheerful and hopeful.

On May 31st a decided increase in the maximum temperature was noted, with some pain in the abdomen, referred chiefly to the region of the ascending colon.

On June 4th an irregular mass was discovered in the right inguinal region, extending upwards to level of anterior spine, and downwards to pelvic brim.

No positive diagnosis had been made in this case, although abdominal tuberculosis had been suspected. Upon the appearance of this mass, a consultation was held with the attending surgeon, Dr. Culbertson, and an exploratory incision advised, which was consented to by the patient and her husband.

The operation was performed by Dr. Culbertson, June 6th. The report of the condition found was as follows:

"Uterus small, normal in position. Both sides of the pelvis filled by a neoplastic mass, apparently tuberculous, which on the right side reached the level of the liver, involving the ascending colon and some folds of the small intestine. The mesentery was also studded with tubercles. No ascites."

The abdomen was flushed with salt solution and closed.

The patient's temperature never rose above 101° and soon descended to normal. She left the hospital August 17th, having regained strength, flesh and color, and all traces of the mass had disappeared.

I saw her April 3, 1897. She looked in fine condition, and called herself perfectly well. Menstruation was regular and painless, and she had no discomfort in pelvis or abdomen.

CASE II. Mrs. D., age twenty-four, was delivered of her third child at the New England Hospital Maternity, May 14, 1896. Labor normal, no laceration. Child healthy. Family history negative. Physical condition during pregnancy good. General appearance healthy.

On the third day after labor, the temperature rose to 104°. She complained of headache. No cause could be assigned for the temperature. During the next two days the temperature ranged lower, then rose again, and on May 22d (eighth day) reached 103.4°.

A very careful pelvic examination was made; and although there was no tenderness, and the lochia appeared normal, the uterus was curetted, with negative result. An examination of the thoracic and abdominal organs was also negative.

From May 22d to 29th, the lowest temperature was 101°, the highest 104.4°. The temperature curve was very irregular, the maximum being often in the morning. The pulse ratio to temperature was slow. The patient complained of no pain, but was depressed and anxious, and perspired profusely.

During the week from May 29th to June 4th the average temperature was decidedly lower, the highest being 102°, the lowest 99°.

On June 4th the temperature rose to 105.6°, and for several days it touched 105° at some part of each day. She grew stupid, slept most of the time, her pulse was quick, often irregular, and, in short, she presented the appearance of one overwhelmed with some poison.

From the 9th to the 13th of June, the temperature again averaged lower, the maximum being 102°. She

¹ Read before the Obstetrical Section of the Suffolk District Medical Society, April 28, 1897.

took food well and seemed brighter, and the pulse was stronger and slower.

On June 16th a slight cough was noticed. No physical signs in chest.

On June 17th she had a chill, and temperature rose to 105.5°, followed by moderate phlebitis in right calf and thigh. On June 19th she complained of tenderness in right inguinal region, and the abdomen became distended. Internally there was some sensitiveness in right adnexa, but nothing definite could be felt. The lochia had ceased. The sensitiveness also disappeared in a few days.

During this time, although quite rational, she answered questions very slowly, as if it took a long time for the ideas to penetrate the sensorium.

On June 21st the cough became more troublesome, and a few sibilant râles were heard in the right lung posteriorly. The sputum was examined, with negative result.

June 23d. She complained of sharp pain in the region of the diaphragm, on the right side.

June 26th. She had severe pain in the right side of thorax below the scapula, and some friction sounds and fine râles were heard there.

From this time the signs of effusion (as manifested by dulness merging into flatness, distant respiration and diminished vocal resonance) successively presented themselves in the right side. There were also apparently patches of consolidation, presumably lobular pneumonia, above the level of the effusion.

In spite of the fact that no local focus of sepsis could be pointed out, this case had been considered as septicemia for lack of any other explanation. The phlebitis, the symptoms of peritoneal irritation, the local pleurites and pneumonia were regarded as secondary manifestations of the infection. Following this idea, the signs of effusion into the pleural cavity were supposed to indicate empyema, and aspiration was decided upon, with the idea of making a permanent opening in case pus was reached. On July 9th, aspiration was performed by Dr. Alexander and myself; but we only succeeded in drawing out about half an ounce of absolutely clear serum. It was therefore concluded that the physical signs were caused by a thick layer of plastic lymph between the chest wall and the lung. An examination of the serum by an assistant pathologist, Dr. Harriet Lothrop, disclosed the presence of the tubercle bacilli. Another examination of the sputum showed the bacilli there also, but not so abundantly as in the serum.

The diagnosis of tuberculosis having thus been established, the patient was permitted to sit up, and was carried out of doors on suitable days. She went home the last of July. At that time her evening temperature was still 102° to 103°, and we expected a rapidly fatal termination.

During August, I saw her once a week at her home in South Boston, where, in spite of poor surroundings, she improved decidedly. Her cough diminished, and she gained flesh and strength; the physical signs in the lung improved slowly but steadily.

In September she went to the Chanung Home, where she gained ten pounds in six weeks; and soon after she left there I examined her chest and could find very little difference in the breathing between the two sides. This opinion was confirmed by Dr. V. Y. Bowditch, who saw her about this time. She had absolutely no cough, so that no sputum could be obtained.

I saw her last in January, and she seemed very well. I have since heard through friends that she continues so, although she has worked very hard all winter tending in a bake-shop from 5 A. M. to 9 P. M.

My interest in these two cases, which occurred within a month of each other, during my service, was further increased by Dr. Alexander, who kindly referred me to another case, which occurred in 1894; and I report this from the hospital records and the private notes of Dr. Alexander, who was at that time resident physician of the hospital.

Mrs. J. T., age twenty-four, American, primipara. Family history good. Health had been good till within the past two years, during which time she had suffered from a pain in left ovarian region, brought on, as she believed, by running a heavy sewing machine. This pain had been quite troublesome during pregnancy, and she was reported to have had a profuse and fetid leucorrhea.

Delivery occurred February 28, 1894, and was perfectly normal. No perineal rupture. Child healthy.

On the fifth day, March 4th, the temperature rose to 103°. No cause for temperature found in thoracic, abdominal nor pelvic organs. On March 7th she had a chill, and temperature rose to 106.8°. Another chill occurred on March 9th.

The patient was etherized, and the uterus curetted and washed out. Some shreds of decidua and placental debris were removed, but they were absolutely fresh in odor and appearance. The lochia had never been fetid. The patient's temperature continued high; there were occasional chills; later, vomiting, involuntary urination and defecation, and low muttering delirium.

Death occurred on March 20th, the twenty-first day after delivery.

The case was considered during life to be one of septicemia, with auto-infection from an old pus-tube (indicated by the persistent pain in the side and fetid leucorrhea). A post-mortem examination by Dr. Mallory revealed no pelvic lesion, but both lungs were completely riddled with miliary tubercles.

(The temperature charts of these patients were here shown.)

We have here three cases of tuberculosis, apparently developing during the puerperium, running a very acute course, two ending in recovery, the third in death.

I cannot find reports of similar cases in any of the text-books and journals which I have consulted. One reason for this may be, that until a comparatively recent period the diagnosis of these cases could not have been with certainty made during life. The diagnosis of Case I was decided by the exploratory incision, a method which in former times would have been considered inadmissible. The diagnosis of Case II could not have been made at all without the bacteriological examination of the secretions. Case III would undoubtedly have been called septicemia if no autopsy had been held. Since comparatively few fatal puerperal cases are allowed an autopsy, other similar cases may have passed unrecognized.

The first question naturally is, did these women present any evidence of tuberculosis before labor. The family history of all three is negative. The physical condition of Case I during pregnancy is reported as poor. She suffered much from indigestion. This might suggest that the tubercular deposit had already

begun in the abdomen. But she was for ten days under observation in the medical wards of the hospital about a month previous to her confinement, and during that time her temperature was normal, and there was nothing recorded to suggest the presence of serious disease. Moreover, there was no marked rise of temperature until ten days after labor.

I know that Osler, in his valuable article on "Tubercular Peritonitis," published in the "Johns Hopkins Hospital Reports," states that some cases run their whole course with a normal or even subnormal temperature, nevertheless, the usual rule certainly is, that fever is one of the earliest and most persistent symptoms of this disease.

The condition of Case II during pregnancy is reported as good, and her appearance confirmed the statement.

Case III had a history of pelvic pain extending through two years, but seems otherwise to have been in fair health.

While, therefore, it is impossible to prove the absence of previous tuberculosis in these women, there is no decided evidence in the affirmative.

What was the primary source of infection? Cases I and II had no contact with tuberculous patients during pregnancy, so far as can be ascertained, and no hereditary tendency toward the disease. Neither had any enlarged glands. Both were in humble but not destitute circumstances. I have no knowledge of the outside conditions of Case III. The suddenness and violence of the outbreak would seem to argue that some focus of infection must have existed which the conditions of the puerperium served to disseminate rapidly.

This question derives peculiar interest from the fact that the Fallopian tubes are now known to be comparatively often the seat of tuberculosis, and though this is in many cases secondary to deposits elsewhere in the body, there is evidence that in a certain number they may be the primary focus of disease. The conditions of the circulation during the puerperal period would be especially favorable to the diffusion of any infection having its seat in the genital canal.

Dr. J. Whittredge Williams, in his article on "Tuberculosis of the Female Generative Organs," read before the American Gynecological Society in 1892, says: "Genital tuberculosis is usually secondary to deposits elsewhere in the body, but in a considerable number of cases is primary in the genitals. Its frequency is much greater than is usually supposed. Only about 25 per cent. of tubercular tubes and ovaries are recognized as such by macroscopical examination. The symptoms are not characteristic: they may be entirely absent or vary from those of a simple catarrhal salpingitis, to the most severe form of pelvic abscess."

In regard to tubercular peritonitis, especially that which is usually complicated with more or less invasion of the pelvic peritoneum, the question whether the infection spread from the tubes upward to the abdomen, or *vice versa*, is of great interest.

In Case I the uterine appendages were apparently buried in the mass of tubercular inflammation. It will be remembered that some time before any evidence of the tubercular mass appeared in the abdomen there was an ill-defined thickening in the region of the appendages. I questioned this patient carefully in regard to any previous symptoms of uterine, or tubal

disease. The only one she gave was a bearing-down pain in the right inguinal region, from which she suffered very much during the whole pregnancy, and which in the early months was so constant as to make her fear a miscarriage.

In Case II the course of the symptoms suggested a diffusion of some poison in the right side of the pelvis, causing pain and tenderness there, then irritation of the peritoneum, diaphragmatic pleurisy, then costal pleurisy and penetration into the substance of the right lung. Here there was no evidence of any previous trouble in any part of the body.

Case III had a history of pelvic trouble and a fetid discharge, and a previous salpingitis was diagnosed from it, but at the autopsy nothing of note was found in the pelvis. At the same time, since the condition of the lungs amply accounted for the fatal result, it is quite possible that a minor degree of salpingitis might have been unrecorded, and as no macroscopical examination of the tubes was made, tubal bacilli cannot be absolutely excluded as a source of infection.

I do not wish to be understood as considering that I have any real evidence to offer as to the mode of infection in any of these cases. I have only endeavored to trace out the slightest clue, hoping it might lead to further investigation on these points in any similar cases.

How do these cases differ from those of ordinary so-called acute tuberculosis? These cases certainly present types of very acute tubercular infection, and two of them at least show a suddenness of invasion and a violence of constitutional symptoms seldom seen in this disease. On the other hand, the favorable termination of two out of three of these cases is very unusual. The time of invasion, the temperature curve and the absence for so long a time of any discoverable lesion makes them liable to be regarded as septic in spite of the absence of appreciable focus in the genitals, since repeatedly septic infection is known to have been diffused from a centre so small that it is not recognizable by ordinary examination.

It is possible that some of the obscure cases of fever in the puerperal woman now and then reported may have been of tubercular origin.

This paper is intended to call the attention of physicians to the peculiarities of the tubercular disease as here displayed, and in the hope that it may bring out reports of similar cases, rather than with any idea of drawing deductions on the subject, since the cases presented are too few to justify this. It seems to me reasonable, however, to feel that there is evidence that some women at least are peculiarly susceptible to the infection during pregnancy and the puerperium, and that special pains should be taken to guard them while in this condition from known sources of infection, such as the contact with tuberculous patients, either in their homes or lying-in hospitals.

THE RECORD BROKEN.—What appears to be an authentic case of a woman who has given birth to four pairs of twins has been reported in St. Louis, Mo. The woman in question, who is only eighteen years of age, has lived in East St. Louis during the past five years and recently applied to Dr. Woods, Supervisor of the Poor, for food for herself and children, of whom all but three are dead. Dr. Woods carefully investigated her statements and found them correct.

ENTEROPTOSIS.¹

BY MARY P. DOLE, M.D., GREENFIELD, MASS.

MRS. A. Was first seen in July, 1893. Was confined one year previous; labor difficult, forceps delivery. Has not been well since. Feels tired. Pain in iliac regions and in soles of feet. Backache. Appetite good, sleeps well, bowels fairly regular.

The cervix and perineum were found badly lacerated, and an operation for their repair was advised, with the expectation that the patient would be wholly relieved.

She was next seen two years later. The lacerations had been repaired, but the patient had gradually grown worse. Has much pain in right lumbar region, especially after standing or walking; the pain extends down the leg and up into shoulder. The backache has increased. Has lost some in weight. Gets tired easily. Is constipated and very nervous. Examination of the abdomen showed: epigastric region depressed, slight distention below umbilicus; stomach reaches one inch below umbilicus; whole of right kidney and two-thirds of left easily felt; lower border of liver one finger's breadth below ribs.

Miss B. First seen in 1892. Has always been delicate. Has much backache. Considerable flatulence and acidity of stomach; occasional nausea and vomiting, but vomits only small amount. Is inclined to be constipated. Menses regular, considerable dysmenorrhea.

Pelvic examination: Uterus retroposed. The displacement was corrected, but with no relief to the patient. The various digestive ferments, antiseptics and tonics, and, by the advice of a New York specialist, lavage of the stomach, were tried with equally bad results. The patient was seen again a year ago. Condition about the same.

Abdominal examination: Epigastric region depressed, slight distention below umbilicus, whole of right kidney easily felt, lower border of liver one inch below ribs, stomach reaches a little below umbilicus.

I have given a brief outline of these cases, not because there is anything striking or unusual about them, but rather because they are everyday cases with all of us, and also because they belong to a very large group of cases to which we formerly gave the names of dilated stomach, floating kidney, neurasthenia, chronic dyspepsia, nervous dyspepsia, or nervous something, but now are looking at them more and more as cases of enteroptosis.

The word enteroptosis, strictly speaking, means a falling of the intestine, but as used at present, it has a more general significance, being applied to a downward displacement of some or all of the abdominal organs. A displacement of portions of the intestine and of the other abdominal organs has long been recognized as an anatomical fact, but its importance as a pathological condition has only within the last ten or twelve years begun to be appreciated. It was in 1886, I think, that Glénard presented his paper on this subject before the Medical Society of Paris, and this marks the beginning of our present conception of this extremely common condition.

The organs most often affected are: first, the right kidney, then the stomach, transverse colon, liver, left kidney and spleen. The displacement may be congenital or acquired.

The causes of the acquired form are, first, those which produce a relaxed condition of the abdominal walls, and, second, those causing downward pressure on the abdomen. In the first group the most important are, child-bearing, diseases producing much general debility, for example, tuberculosis, typhoid fever, anemia and neurasthenia, and malnutrition from insufficient or improper food.

In many cases of anemia and neurasthenia, however, the enteroptosis is probably the cause rather than the effect.

In the second group are: lacing, letting the skirts drag down on the abdomen, overwork, lifting heavy weights, etc.

In considering cases of enteroptosis, we have to take into account the fact that nearly always there is associated with the displacement a myasthenic or atonic condition of the stomach and bowels, and often it is to this more than to the displacement that the subjective symptoms are due. It is also true that a considerable degree of enteroptosis may exist without producing any symptoms. Such cases, however, are exceptional.

In the diagnosis we have to consider the subjective symptoms, objective signs, and the course of the disease.

The most common symptoms are a feeling of fullness and pressure in the epigastrium, flatulence, cardialgia, variable appetite.

The stomach symptoms differ from those found in most other diseases of the stomach by being more irregular. They do not depend upon the kind of food taken nor upon the stage of digestion; that is, they are just as apt to occur after taking liquid as after solid food, or when the stomach is empty as when full, and *vice versa*. An almost constant symptom is habitual constipation, in some cases alternating with diarrhea. The constipation is due partly to the atony of the muscular coat of the intestine, and partly to the abnormal flexing or doubling up of the intestine by its prolapse, which interferes with the peristaltic motion.

In many cases the nervous symptoms are the most prominent. There is often headache; almost always more or less backache, frequently pain in the abdomen which wanders about from one place to another.

Patients with enteroptosis are, as a rule, thin, spare people, and, therefore, it is comparatively easy to make out the position of the different organs. The stomach is found reaching to or below the umbilicus. The whole or part of one or both kidneys is to be felt. The transverse colon is descended; also in many cases the liver and sometimes the spleen.

Examination of the stomach contents shows that digestion in the stomach is normal, or perhaps retarded. In the morning the stomach is empty or contains simply a small quantity of gastric juice, with perhaps some bile, but no food.

The disease runs a chronic course, with many remissions and exacerbations. In the more marked cases nutrition is much interfered with. The patient loses in flesh and strength. Is easily fatigued. Of some diagnostic value is the favorable effect of physical and mental rest, and the opposite. The patient feels fairly well if she does but little.

The only disease which I shall consider in the differential diagnosis is dilatation of the stomach, or more correctly termed, mechanical insufficiency. Until recently every stomach that reached to or below the umbilicus was considered dilated. Further careful

¹ Read before the Massachusetts Medical Society, June 8, 1897, and recommended for publication by the Society.

study has proved that a great majority of these are simply descended, and that cases of mechanical insufficiency are comparatively rare.

A very characteristic symptom of mechanical insufficiency is the vomiting at intervals of large quantities of food and liquid, which, on standing, separates into three layers. The lowest consists of food, the middle of a grayish, turbid fluid, the upper of a brownish froth. The vomited material may contain food that was eaten two or three days before.

In enteroptosis the amount vomited is small and does not contain food eaten the previous day.

In mechanical insufficiency thirst is much increased, the amount of urine passed in twenty-four hours is lessened and the skin becomes dry — symptoms which are not usually present in enteroptosis. In mechanical insufficiency the emaciation is more marked, the stomach symptoms are more regular and their intensity is more dependent upon the kind of food taken.

In cases of doubt, very conclusive evidence can be gained by giving the patient a test supper, consisting of cold meat, bread and tea, and then the next morning examine the stomach contents.

If there is mechanical insufficiency a considerable quantity of food and liquid will be present, having a characteristic sour odor, and, on standing, separating into three layers. Under the microscope one finds yeast fungi and sarcinae, whereas if it is a case of gastropnoia the stomach is either empty or contains only a small amount of gastric juice. No food is present, and the yeast fungi and sarcinae are wanting.

Prognosis: The disease carries with it no serious danger to life, but, in most cases, it does reduce one's power to do either physical or mental work, and often the patient is more or less of an invalid all her life.

Treatment: Remove as much pressure and weight from the abdomen as possible. Corsets should not be worn. The patient should wear few skirts and light ones, and these should be supported from the shoulders. Give a very nourishing diet, — one rich in carbohydrates and fats, plenty of good milk, cream and butter.

Tone up the muscles of the abdominal wall, stomach and bowels by cold bathing and rubbing, and, best of all, by abdominal massage and the Faradic current. In some cases an elastic abdominal binder gives much relief to the patient.

The medicinal part of the treatment is very secondary. Strychnia probably does good, and, where there is much flatulence, resorcin or beta-naphthol may be of service.

In regard to the misplaced kidneys, the question of nephrorrhaphy will often come up. In many, probably in most, of the cases, the symptoms are due more to the displacement of the other organs, so that until a way is found of stitching up all the abdominal organs the patient cannot be wholly relieved by surgical treatment. However, there are cases in which the chief suffering is due to the nephroptosis, and in these cases nephrorrhaphy is of benefit to the patient.

I wish to acknowledge my indebtedness to Professor Litten and Dr. Boas of Berlin, in whose clinics it was my privilege to study for a time, and to whom I owe the few thoughts which may be of interest in this paper.

TYPHOID fever is reported to be epidemic at Dawson City; several miners have died of the disease.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

JAMES G. MUMFORD, M.D., SECRETARY.

REGULAR Meeting, Monday April 26, 1897, Dr. A. L. MASON in the chair.

DR. WILLIAM T. PORTER, by invitation, read a paper on

THE PHYSIOLOGY OF THE SYMPATHETIC NERVE.

DR. F. B. LUND read a paper on

ENTEROPTOSIS AND MOVABLE KIDNEY.¹

DR. THOMAS DWIGHT: The paper is a very interesting one in many respects, and opens many questions that I only wish I had felt properly prepared to discuss. The first point that naturally occurs is as to the general principle of the fixation of the abdominal viscera, and that is no single elementary principle. One of the most important factors beyond question is the strength and tonicity of the abdominal walls. Then we have to consider the support of the viscera by ligaments and otherwise. The liver is the organ apparently which moves the least, in spite of its weight. The ultimate cause of that is to be found in the fact that the liver and diaphragm develop as one; so much so, that some, though I cannot agree with them, hardly like to talk of a posterior surface of the liver, looking at it as practically one with the diaphragm. The union there is very firm by areolar tissue, much denser than that which usually connects other organs to the walls. Thus the intestines originally develop in a median loop, and after going through a number of twists and curves certain parts of them get stuck to the abdominal wall, and the peritoneum which covers the abdominal wall, and the loop which has come to lie against it is changed into areolar tissue. We do not find in this place the same strength of adhesion as between the posterior wall of the liver and the diaphragm.

In the intestine there are one or two tolerably fixed points: one, of course, is the beginning of the stomach where the esophagus goes through the diaphragm. That is held up in a variety of ways. We may assume that that is practically fixed. Again, there is the first part of the duodenum, not its very beginning, where it is caught up against the liver, and near which passes the bile-duct which runs into the second part. Finally, there is the termination of the duodenum, which is held up to the second lumbar vertebra and the under side of the celiac axis by a band of fibrous tissue which originally was muscular fibre. Those are pretty fixed points; and if you look at this diagram, you will see first that in all these cases of prolapsed viscera the stomach is very much enlarged. In the second place, it stands to reason that the upper part of the stomach, where it goes through, cannot fall down; consequently, if the stomach is to fall, there must be a general enlargement of that organ; and this seems to be the case. Though the pylorus undoubtedly does fall, it does not fall so very much.

As to the so-called ligaments, simple bands and folds of peritoneum which pass from the wall on to a viscus hardly deserve the name of ligaments. I think it is misleading, and do not believe they have a restrain-

¹ See page 343 of the Journal.

ing power that will resist any very great tension; they will gradually give. You see that shown in a great many cases.

Then, again, with regard to tight lacing, that is one of those things so evidently wrong that people are apt to attribute to it much for which it is hardly responsible. I can hardly understand how it can drive a stomach downwards. It is said so generally that it does, that I hesitate to deny it; but I fail to see the mechanism by which it acts. I should think it would rather tend to make an hour-glass stomach or to crush it together or shove it up. How it can be driven down is to me, at all events, not clear. As to the treatment, speaking merely theoretically, it seems to me that what Dr. Lund suggests of the support and of the efforts to strengthen the abdominal walls is the most efficient part.

DR. F. S. WATSON: I must approach this subject from the clinical side, and will confine my remarks to movable kidney. I am much interested in what Drs. Lund and Dwight have said. The subject of movable kidney has occupied me a good deal in the last four years.

Glénard's views are so well known and at the first glance are so extreme, that it was not surprising to find them in some part contradicted by the experience of others. That movable kidney occurs independent of general or partial ptosis of other abdominal viscera, is attested by the following facts. Clinically, surgeons note in a certain number of cases the absence of any evidence of enteroptosis, which Glénard claims to be the *sine qua non* of movable kidney.

In the published post-mortem observations a considerable proportion of movable kidneys are noted in the absence of ptosis of the other viscera.

What degree of mobility constitutes a movable kidney? In my observation the ordinary excursion of the kidney following the movements of respiration with the patient lying upon the back or side (these observations during operations) is from one to one and a half inches, never more than two. Probably an excursion that exceeds three inches may safely be called an abnormal mobility. At the very least we may say that, when during physical examination pressure upon the kidney in the loin forces it forward so that its outline can be clearly felt below the ribs by the fingers of the other hand through the anterior abdominal wall, or when during the forced inspiration the upper end of the kidney descends so far that it can be grasped below the ribs, between the thumb and fingers and held in this position, the organ has *certainly* an abnormal degree of mobility.

I hear physicians from time to time speak of detecting the kidney when of normal size and condition by bimanual examination. I confess my inability to do this except in a very thin patient and with relaxed abdominal wall. When a kidney is easily palpated under any other conditions than the above, it is pretty safe to infer that it is enlarged or mobile.

Next, as to the dependence of certain symptoms upon movable kidney *per se*, I believe that the majority of cases of the latter condition do not give rise to symptoms of any importance; but I am equally sure that a certain number of well-defined and sometimes serious symptoms are produced directly by movable kidney alone; for I have watched their gradual evolution in three cases at least, from the beginning and seen their complete disappearance follow nephrorrhaphy.

The examples of cures from the latter, and from many sources are too numerous to be disregarded. It must be confessed that it is often very difficult, however, to separate cause and effect, especially in those cases in which neurasthenic symptoms predominate.

Another matter upon which I wish to touch is the mechanism by which one of the most important symptoms of mobile kidney is produced. I refer to the crisis of pain. In two out of five post-mortem examinations which I have had the opportunity to make within the past year, and two of which I owe to the kindness of Dr. Lund, I noted in the peritoneal covering of the kidney the relaxation of which permitted its descent, the presence of a number of strong transverse fibrous bands crossing the peritoneum in front of the kidney at intervals of from one to two and a half inches, which effectually prevented rotation of the kidney either on its long or short axis, whether upon changing position of the body or by actual manipulation. In the three remaining cases these bands were absent and the peritoneal covering of the kidney was so generally relaxed that these rotations took place upon change of position.

Now, the crises of pain are probably almost always due to the sudden enlargement of the kidney following upon torsion of the renal vessels perhaps, but especially upon twists or kinks of the ureter so marked as to produce complete obstruction to the flow of urine through it. Simple descent of the kidney, unless the ureter be abnormally fixed at some point in its course, will not produce these. Rotation upon one or the other axis of the organ, or descent of the kidney—the ureter being abnormally fixed at some point—are necessary before they can occur, and furthermore a diminution of perinephritic fat, and a relaxation of the peritoneal covering uninterrupted by such bands as I have described, are also requisite conditions. When all these conditions favoring rotation are present, it may occur at any time upon appropriate and sufficiently forcible movements of the body. Albarran has recently shown that the enlargement of the kidney when the ureter is suddenly obstructed—as by ligature—is due almost entirely to congestion and not to distention by retained urine. Clinical evidence confirms his experimental conclusions in this respect, and the relative rarity of hydronephrosis in connection with movable kidney is thus plausibly explained.

DR. LUND: The point to which Dr. Dwight has alluded in regard to the catching up of the pylorus underneath the liver is certainly brought out in the drawings in a very striking manner.

I should like to ask Dr. Watson what measures he took to ascertain whether or not enteroptosis was present in the cases of movable kidney which came under his observation.

DR. WATSON: These cases were during life. There have been cases in which there had been distinct absence of symptoms referable to the digestive apparatus. These cases have been percussed by me with reference to the question of dilatation of the stomach. I have never blown up the stomach. In a patient who has no symptoms referable to the digestive tract, it is fair to assume that the enteroptosis has not gone to great degree. There is no means of confirmation if the case does not come to autopsy.

DR. LUND: While I must agree with Dr. Watson's views to the extent of admitting that movable kidney

may occur without a marked degree of general enteroptosis, and while Gléuward's contention that movable kidney is always a manifestation of a general enteroptosis is probably too extreme, I cannot help being led by my observations and study to believe that movable kidney will be found to be combined with enteroptosis in a very large majority of the cases. The kidney cannot move without a relaxation of its peritoneal covering, and the causes which lead to such relaxation, namely, weakness of the abdominal walls, absorption of fat, stasis of fecal current, with ptosis of the stomach and intestines, etc., also lead to a general relaxation of the peritoneal supports of the other abdominal viscera.

Or, from another point of view, supposing the mobility of the kidney to be the primary lesion, so to speak, the kidney gliding downward loosens its peritoneal covering; this relaxes the support of the hepatic flexure of the colon, which falls and drags down upon the duodenum, and dilatation of the stomach and gastro-ptosis ensues.

I believe that ptosis of the kidney cannot occur without more or less associated enteroptosis, and that in our treatment of these cases, we must take into account the fact that we have to deal, not only with ptosis of the kidney, but with a greater or less degree of associated ptosis of the other viscera.

The argument that enteroptosis has not generally been found associated with movable kidney in the practice of the majority of physicians falls to the ground, for the reason that attention has not been directed to it, and no means, such as artificial distention of the stomach, etc., have been taken to ascertain whether it was present or not.

On the other hand, we can all of us recall cases of movable kidney which have been operated upon; and while they have been perhaps relieved of crises of pain from twisting of the renal vein, from intermittent hydronephrosis, etc., have continued to lead a miserable existence as the victims of intestinal indigestion and general neurasthenia. These cases, I believe, are almost always the subjects of general enteroptosis, in the treatment of which nephrorraphy is only one step.

I do not wish to state that nephrorraphy is not indicated in movable kidney associated with enteroptosis, for I believe that the kidney is the only one of the abdominal organs except the uterus which can, as a rule, be satisfactorily fixed and held in place by suture, and I believe that it is impossible to fix and hold it satisfactorily by padded abdominal bandages, but I feel very strongly that nephrorraphy, if it is to be therapeutically successful, must be supplemented by a course of treatment directed to measure the muscular tone of the abdominal muscles, to maintain intra-abdominal pressure, and regulate the disordered digestive system.

In regard to Dr. Dwight's statement of the difficulty of understanding how compression of the lower thorax by tight lacing could cause ptosis of the stomach, I would say that the mechanism is believed to be somewhat as follows: The lateral area of the thorax being compressed, the distention of the stomach which takes place when it is filled with food must expand it in a downward direction, and this downward expansion must both elongate the stomach and drag upon the gastro-hepatic omentum, not only with the weight of the contained food but also with the force of the lateral pressure.

SUFFOLK DISTRICT MEDICAL SOCIETY. THE SECTION FOR OBSTETRICS AND DISEASES OF WOMEN.

C. H. HARE, M.D., SECRETARY.

REGULAR Meeting, Wednesday, April 28, 1897,
DR. E. W. CUSHING in the chair.

DR. C. G. CUMSTON: The first specimen I would like to show is an instrument for examining human milk. It is very simple. Place a drop of milk on the centre of this glass and put it against the black and hold it so that the light comes on it and you can tell whether the milk is poor, rich, normal, very rich, contains cream, etc. It is a practical instrument for rapid examination of any suspected female milk.

I have a photograph of a case I saw at the Dispensary of secondary syphilis and I made the diagnosis of precocious tertiary syphilis of the genital organs. The roseola was fading. She had sore throat and alopecia to a certain extent. Around the anus were a large number of round ulcerations and a condition I have seen once before, — enormous hypertrophy of the labia with ulcerations extending all along the borders, and if this photograph had been taken properly a large number of ulcerations would have been seen around the external orifice of the vulva and the small lips.

The next specimen is a pretty case of dermoid cyst of the ovary, and this illustrates the fact that a patient may become pregnant even with both ovaries involved, as in this case. Upon section I removed this cyst and finding the other ovary was undergoing sclero-cystic degeneration, I removed that. The patient was thirty-nine, had had eleven children and four miscarriages. The photograph shows the cyst as it developed. You can see a large amount of ovarian tissue and the cyst cut open simply contained the cheesy matter usually found in these cysts and on one side of it a small area of skin growing with a few hairs in it. This case would have been more properly treated by vaginal hysterectomy, but as I thought only one ovary would have to be removed the abdomen was opened instead.

DR. A. K. STONE read a paper on

ENTEROPTOSIS AS A CLINICAL FACTOR IN THE DISEASES OF WOMEN.¹

DR. TWOMBLY: I have been very much interested in listening to this paper. In our specialties we often forget the general side of the subject, though we shall consider all the environments in treating disease, and all the factors that may conduce to that disease. For instance, in women's troubles we should not feel that they are all found in the pelvis, but that they may be due to other conditions arising perhaps from malnutrition, from tight lacing, or depressing circumstances and influences, and this paper has called forth another factor in showing us that there may be prolapse of the abdominal organs, which is very seldom considered in the case. We would put our patients on the road to recovery more frequently if we bore all these factors in mind. Dr. Stone has said, in certain cases the treatment is clear. Where we have a loss of the perineum, we naturally must furnish that support by operation, and operative procedures furnish the cure, but in other cases, where we do not see that a special pelvic treatment is the thing to restore the general health, we must look further, and we find it in just

¹ See page 332 of the Journal.

such conditions as he has pointed out to us to-night. I believe one of the ways of treatment in such a prolapse of the viscera is that of the knee-chest position, but I am surprised to see how unwilling the patients are to help themselves. You will instruct your patients very carefully how to take this position after all clothing has been removed; the best possible time being when they are ready for bed. You show them how to take that position; not on the elbows, and yet invariably when they come back and tell you what they have done, they have kneeled down and put their elbows thus, and turned the head and looked around, but have not got way down. Of course the result is not so good as if we had the proper angle allowing all the viscera to fall forward toward the ribs. I hardly think after this position has been assumed and they turn on their side to lie down and go to sleep that it makes much difference on which side they turn. If they lie on the right side we would suppose the transverse colon, which is prolapsed, would be drawn more into its proper place. Whether that is the result I do not know. If they have a dilated stomach and get in this position and lie on the left side we would suppose that it would allow the walls of the stomach to contract a little and go up towards its natural position. How far that succeeds I have yet to learn, but where a patient practises faithfully this knee-chest position I find that in a great number of cases they cease to complain of this tremendous dragging backache and pain, and say they are greatly relieved and that is without especial reference to the position of the uterus. Of course, where we have retroversion, we often use that position, the force of gravity helping to replace the uterus. Another thing is the abdominal support which has been mentioned. In a case I have in mind, after the removal of pustules by the abdominal incision where an abdominal support was necessary, I have known it to be so adjusted after the patient left the hospital that when she came back six months afterward complaining of terrible pressure and dragging in the lower part of the abdomen, on examination it was found she wore the belt about the umbilicus. The perineal straps bothered her, and she took them off and had a belt which pressed the whole viscera down into the pelvic cavity as much as it could. No wonder she complained of lack of support and the old feeling coming back. When it was explained to her how the abdominal supporter should be used, and it was replaced in its normal position, the comfort she experienced was remarkable. We cannot impress too strongly on our patients the importance of the right ways in carrying out treatment and the proper support.

DR. C. J. ENEBESKE: I am very much interested in the subject because it has happened several times that women have been sent to me for gymnastic training who have complained of symptoms referable to the neurasthenic type without any probable organic cause. I recall one young woman who was under my training three months and improved very much. For some time it was a question whether to send her to a gynecologist for examination under the supposition that possibly there existed a prolapse or sagging down of the uterus, because some of the symptoms she complained of — backache, shooting pains down the thighs — pointed somewhat in that direction, but no such examination was made, and in my direction of the exercises she received I took into consideration the possibility

of such sagging existing. Among the exercises which I gave in this case were also the exercise which has been referred to by the previous speaker, the knee-chest position, and while it is not possible for me to conclude anything from such a case as that, and while it is not possible for me to conclude whether that particular position, is better than other positions we practise, still I think there are reasons to think that position may be of advantage in relieving the symptoms of ptosis in any of the organs in the abdominal cavity. At present I have under training a case of enteroptosis. She has been under training about six weeks and the neurasthenic symptoms are very much relieved. There is in her case a sagging down of the right kidney. I have not examined lately the position of the kidney. The plan of treatment in her case has been in the beginning passive massage. She was sensitive in the beginning. An attempt to give massage seemed to have an exciting effect upon her, so I proceeded in a gentle fashion, but I succeeded in overcoming those difficulties and at present I direct all her training to fortification of the abdominal wall. She can now take comparatively vigorous exercises of such character that the greater part of the work is localized upon the abdominal muscles, and these last few weeks she has felt very much relieved of all the symptoms of which she has formerly complained. That is all the experience I have had in this direction, and of course it is entirely insufficient for me to base any conclusion upon.

DR. CUMSTON: I have taken a great deal of interest in the paper, particularly because the subject of enteroptosis was being worked out by Gléuad when I was a student and there was a great deal of enthusiasm shown over it and the clinics were quite full of typical cases which were demonstrated before us and I had the opportunity of observing quite a large number of them as a student with Gléuad at Lyons. Since I have been in practice I have seen one or two typical cases, both of them in the better class of society, women who did not do much of anything but amuse themselves, and I would like to report one of these cases, particularly because it is an extreme one. I would also like to make one or two suggestions that occurred to me while the paper was being read. In the first place, regarding the examination of these patients. It seems to me the only proper way to arrive at an exact diagnosis of the condition of the abdominal viscera is to see your patient in bed and entirely undressed. By this means you will be able to see the typical shape of the abdomen which is characteristic of enteroptosis, that is to say, without corsets it is very much larger in the pelvis than above. Another point I think the essayist did not mention, are those cases in which enteroptosis occurred simply from loss of flesh. When I was studying, the theory was that a great many cases of floating kidney and enteroptosis and ptosis of the stomach and all the organs were due to a loss of flesh especially over the kidney, where the cushion which usually holds them became absorbed and the kidney lost its anchoring and floated. The patients I have seen have been extremely thin.

Regarding the treatment, I have no experience with the gymnastics advised nor the positions advised. I have not followed the literature of this trouble very closely. The treatment I have tried in my own cases has always been trying to produce as much fat as possible, and that has been accomplished by the Weir

Mitchell cure combined with overfeeding when they would submit, and if they would not go to bed and stay a number of weeks I have ordered rectal injections of olive oil every morning, stopping every six days and resuming three days later, and in addition giving glycerine by the mouth. The patient under consideration has been under treatment about three weeks and is receiving per rectum about three tablespoonfuls of olive oil with one grain of pancreatin every morning and 6 or 7 grains of glycerine by the mouth. The history of this patient is as follows: about six years ago she complained of some obscure pelvic pains and consulted one of our prominent gynecologists who advised curettement, which was done. There was some complication after the operation which kept the patient in the hospital five or six weeks. She felt worse after the operation. She consulted a number of gentlemen, all of whom told her about the same thing, — that there was some trouble in the adnexa, but gave no definite conclusion as to what it was. Then she consulted her family physician and he told her there was inflammation of the uterus, and used tampons. I saw her about six months ago. I could not make out much of anything, perhaps slight enlargement of the ovary on the right side, and I advised her to do nothing. She said later that she had ceased all local treatment, she had not had so much pain in the abdomen, but that the digestion was very bad. I treated her on *nux vomica* and *gentian* and the appetite improved, and I did not see anything of her until about two and a half months ago when I was sent for in the afternoon by telephone, saying she was very sick. I found she had been suddenly seized with very severe pain in the right lumbar region, which to all appearances I should have taken to be either a renal or a biliary colic, and, as the abdomen was extremely tender in all points, I could not make a thorough examination. Two or three days later when the pain had subsided, I had her remain in bed and examined her carefully, with the result that I found both kidneys so floating that I could push them about like billiard balls and the stomach might have been four fingers' breadth below the umbilicus. I took her to Dr. Green, of Leach & Green, and he has made a suitable belt. Since that time all symptoms have subsided and she is making flesh, 750 grains in two weeks. I think that case would represent a very typical one of general ptosis of the abdominal organs, particularly from loss of flesh, which this patient has been steadily doing four or five years. She weighed about 130 and now weighs 108 or 109, and also shows how gynecologists should be on the look-out for ptosis of the abdominal viscera.

DR. CUSHING: In a number of cases, in which operation has been performed for abdominal fixation for obscure and severe symptoms, where there was retroversion, and the uterus has been fastened to the abdominal wall, I have observed during the operation that the stomach and the large intestine would be low down, sometimes strikingly so, so that as you opened the abdomen the stomach would be apparent even through a rather low incision. I never happened to think of it until this moment, but I have noticed it. It is curious how the symptoms attributed to enteroposis fit in with many cases where we have laid the blame to the retroversion of the uterus, or to a commencing prolapse, which is probably only part of the general condition, and I have often wondered why

even a slight operation, like curetting in endometritis where there was subinvolution of the uterus, would be of such importance in re-establishing the health of the patient and have concluded that the rest and careful diet had fully as much to do with it as the operation. I have thought sometimes that if we could take these wretched worn-out women and feed and nurse them a month or six weeks it would do as well as any operation. They are not willing to do that without operation. If you try to put them to bed and keep them without operation they think they cannot afford the time. I think Dr. Stone will have done a great service if he can show the gynecologist how a great many of these cases can be cured without operation, because there is a tendency abroad to think some operations are performed which are not really necessary and, at any rate, it is well for gynecologists to think of some other way of curing patients except by operating on them. *Non semper arcum tendit Apollo.*

DR. CALL read a paper on

ACUTE TUBERCULOSIS IN PUERPERAL WOMEN.*

DR. CALL: The special interest in the cases which I have spoken of was that they were cases where apparently there was nothing of the kind before the labor, and yet in looking up the question of miliary tuberculosis it is stated that a case of miliary tuberculosis invariably ends in death. In these cases one followed that course in twenty-one days. Case I was not very violent. In Case II the temperature and the symptoms were as violent as in Case I, and yet she has entirely recovered.

THE BRITISH MEDICAL ASSOCIATION AT MONTREAL.

SECTION OF GENERAL MEDICINE.

(Concluded from No. 11, p. 271.)

THIRD DAY.

The morning session was opened by a paper by DR. WILLIAM HUNTER, of London, Ontario, on

CHOLELITHIASIS.

He dwelt particularly on the causation of this very frequent disease, from which seven per cent. of mankind suffer more or less. With respect to the ordinary (predisposing) causes there has been little advance for 150 years. Our predecessors knew that stagnation and inspissation of bile and those agencies which produce this (sedentary habits, elderly life, tight lacing, etc.) had a large part in the causation, and that women are five times more subject to the disease than males.

The reader regarded cholelithiasis as rather a local disease of the bile-passages than a constitutional disease. The calculi are composed of a nucleus of bilirubin and calcium salts, surrounded by layers of cholesterine. Stagnation of bile favors precipitation, but something else is needed. This factor, the essayist thinks, is the agency of micro-organisms. In cholelithiasis an excess of cholesterine is formed under the influence of catarrhal inflammation of the bile-passages, particularly the gall-bladder. This substance is one of the products of disease of the mucous membranes generally, and is a resultant of the degeneration of epithelial cells. It has been possible to trace its form-

* See page 342 of the Journal.

ation from degenerated mucous cells in the gall-bladder. It is the basis of the viscous masses seen in the gall-bladder in catarrhal inflammation. The cause of the catarrh is stagnation of the bile and invasion from the intestine of micro-organisms; the colon bacillus, the typhoid bacillus, etc. Stagnating bile leads to infection (experiments of Dupré and others). Cholelithiasis is often met with as a sequel to typhoid fever, and the Eberth bacillus has been detected in such cases; in fact, this bacillus has been known to sojourn in the gall-bladder for months after recovery from enteric fever. The microbe readily gains access to the gall-bladder from the intestine.

In some cases gall-stones are formed in the intra-hepatic ducts. This can hardly be from migration. Rather let us suppose that it is due to a catarrh of the intra-hepatic ducts set up by an excretion of irritant products through the bile. His own experiments favor this view. He introduced a substance into the system which excited violent inflammation of the bile-ducts and jaundice.

In the treatment of cholelithiasis the chief indication is to flush the bile-passages with water. The administration of Vichy water, of water with Carlsbad salts is of undoubted efficacy. Salicylate of soda is an active cholagogue. There is no such thing as "lithotriptic" medication. Olive oil dissolves gall-stones *in vitro*, but surely cannot have any direct action on gall-stones in the body.

DR. GRAHAM, of Toronto, followed with an excellent paper on

THE SYMPTOMS AND DIAGNOSIS OF CHOLELITHIASIS.

Sometimes calculi in the gall-bladder are latent for years or for a lifetime, and produce no symptoms, (one-tenth of all cases). Among the obscure symptoms are bilious attacks and pressure over the stomach after food. When microbes get access to the gall-bladder and provoke an inflammation there is pain and tenderness over the gall-bladder or epigastrium, nausea and vomiting. There is apt to be some localized peritonitis, and tension of the rectus muscle; fever of a remittent type. There is bilious colic in less than half of the cases. In the reader's experience 18 cases were sequels of typhoid fever.

The reader gave details of several cases of biliary colic *without calculi*, and several of the subsequent speakers reported similar cases, the absence of calculi being proved by an exploratory operation.

Jaundice is often absent. This is especially the case when the calculus lodges in the cystic duct. Examination of the urine often helps clear the diagnosis. In true cholelithiasis there will be found bile pigment in the urine.

DR. WILLIAM OSLER called attention to two points:

(1) the infective processes in connection with gall-stones; and (2) the relation of typhoid fever. As for the latter, it is known that the typhoid bacillus may exist in the body without causing typhoid fever (like the pneumococcus, which is often a harmless parasite). There is reason to believe that the typhoid bacillus, existing in the gall-bladder as a tenant, may, under the proper conditions, cause gall-stones to be formed.

As to the relation of infection to the attack, in very many cases there is an acute infectious fever, evinced by the usual signs of rigors, high temperature, swollen spleen, etc. He believes it possible that in gall-stone colic we may sometimes have the colic without any

stones being present (nervous phenomena of an inflamed gall-bladder). The physician, however, ought never to assume this in any individual instance.

As for the association of fever with cholelithiasis, there are four groups:

(1) The fever is associated with a chill, and passes away in a few hours — temporary catarrh of the gall-bladder.

(2) The fever is associated with acute cholelithiasis. There are no septic features or suppuration.

(3) The third is what Charcot calls "hepatic intermittent fever," and may exist for a series of weeks or months. There are occasional attacks resembling malaria (severe rigors followed by sweats). Jaundice is sometimes present. The paroxysm is single, rarely repeated with regularity. No fever in the interval. The gall-stone is in the duct, generally in Vater's ampulla.

(4) The fever is associated with suppurative disease of the bile-ducts and abscesses of the liver.

DR. HANDFORD, of Nottingham, said that he had never observed the connection between typhoid fever and cholelithiasis of which mention had been made. Has never seen jaundice complicating typhoid fever. He is inclined to believe that a large proportion of cases of biliary colic are not connected with the passage of gall-stones. The pathology is still unknown. Gall-stones are seldom found. If they really existed what becomes of them? Are they broken up in the alimentary canal?

DR. MACKINNON, of Guelph, has seen two cases of suppurative inflammation of the gall-bladder as a sequel of typhoid fever.

DR. PASTEUR, of London, alluded to the difficulties of diagnosis of gall-stone colic, and of the mistakes which have sometimes been made by both physicians and surgeons, the laparotomy failing to confirm the diagnosis.

DR. ATCHESON, of Galt, asked if drinking hard water predisposed to cholelithiasis, and remarked that this disease is very common in the locality where he lives and where the drinking-water is impregnated with lime.

DR. OSLER paid a well-merited tribute to the contributions of surgeons to the literature of the diseases under discussion. He who knows the subject only from the standpoint of medicine knows only half. The work of Mayo Robson and other surgical writers on diseases of the biliary passages is of the utmost importance to the medical practitioner. The work of the past few years is remarkable for its suggestiveness, if not conclusiveness.

DR. FRANCIS H. WILLIAMS, of Boston, read a paper, with illustrations, on

SOME OF THE MEDICAL USES OF THE RÖNTGEN RAYS.

The substance of this paper has already been communicated to the Massachusetts Medical Society, and printed in this JOURNAL. Dr. Williams's paper was well received by the Section of Medicine, as indicating another valuable means of diagnosis of chest affections; and Dr. Williams was complimented for his original investigations in this new field of study.

DR. MACKINNON, of Guelph, read a paper on the

EMPHYEMA OF PNEUMONIA.

which contained several interesting observations of purulent pleurisy occurring in connection with or as a sequel of pneumonia, and due to the pneumococcus.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 30, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

NATURE AND TREATMENT OF MÉNIÈRE'S DISEASE.

In 1844, Flourens proved that section of the semicircular canals in the internal ear produces very marked troubles of equilibration in animals, independent of any lesion or traumatism of the cerebrum or cerebellum. This conclusion has been corroborated by subsequent experimental physiologists.

In June, 1861, B. Ménière made a communication to the Academy of Medicine, Paris, France, in which he gave a description of the disease which now bears his name. He called it "aural vertigo," and located it in the internal ear. His conclusions, as first formulated in the *Gazette Médicale de Paris*, were as follows:

"(1) An auditory apparatus previously perfectly normal may suddenly become the seat of functional disturbances consisting in noises of a variable nature continuous or intermittent, and which may be accompanied sooner or later with a diminution in hearing. (2) These functional troubles having their seat in the internal ear may give rise to cerebral disease, such as intense vertigo, uncertainty of gait, turnings to the right or left, and falling, and these may be attended with nausea and vomiting and syncope. (3) These manifestations, which are often of an intermittent type, are at last followed by deafness, gradually growing worse and often the hearing is at last totally and suddenly lost. (4) All this tends to the belief that the lesion which is the cause of these functional troubles is in the semicircular canals."

Since this publication, numerous important communications have appeared, confirming in the main the theses of Ménière; among the most noteworthy of these are the contributions of Knapp, Burnett, Charcot, and Gilles de La Tourette.

Burnett accepts the view that in every case of ear vertigo the semicircular canals are irritated and cause the vertigo, but the primary lesion may not be there; the seat of the irritation being undue pressure on the drum-head, on the ossicles, and mediately through the

labyrinth fluid upon the ampullæ of the semicircular canals. Ménière's disease, according to Ménière, presupposes a perfectly healthy ear. Such instances of aural vertigo occurring previously in healthy ears are very rare, all cases observed by Dr. Burnett being characterized by symptoms of a previous disease, usually catarrhal, of the middle ear.

Charcot's lectures on this disease, in the second volume of his "Lectures on Diseases of the Nervous System," are especially valuable, though now twenty years old. He had seen ten or twelve well-marked cases; and he describes the main features of the disease in a manner that has never been excelled. He called attention to the great frequency of noises in the ears in connection with this disease, — the disease being necessarily ushered in or accompanied by whizzing, buzzing or roaring sounds; and to the especial character of the vertigo, which was "the sensation of a movement of translation of the entire body, from behind forward, from before backwards, etc.," while very often the subjective movements would speedily find expression in a tumble or a somersault. Almost always nausea and vomiting would mark the end of the crisis. Generally at the onset of the disease, the vertigo appeared under the form of distinct crises of short duration separated by intervals of calm; afterwards the attacks approached each other, became subintractant, and formed "a vertiginous state, permanent so to speak, in the midst of which appeared now and then paroxysms reproducing all the phenomena of the old crises." The subject of Charcot's first lecture was a victim of purulent otitis media.

Passing by an able and original paper by Mettler, of Chicago,¹ who thinks "that we are not justified, in view of the few physiological and pathological data still at hand, in assigning all cases of vertigo with loss of hearing to an unknown and undemonstrable lesion of the internal ear," a brief notice of a recent contribution by Gilles de La Tourette² is in place. He reports a well-marked case; the patient was presented to the class. This man had been a victim of the disease for five years. After having for some time suffered frequent attacks of vertigo, generally ushered in by a fall, he subsequently had chronic vertigo "with frequent acute episodes." In the right ear was a constant whizzing noise; the hearing in this ear was diminished. He had been several times a patient at the Hôpital Hérold, always getting better under a treatment by sulphate of quinine, then relapsing after leaving the hospital and discontinuing the treatment.

This writer sums up the lesions of the ear capable of producing labyrinthine vertigo. Sclerosis of the tympanum is a frequent cause, supervening particularly in the gouty, in the victims of arterio-sclerosis. It begins generally a little past middle life. Producing ankylosis of the ossicles with loss of their elasticity, this sclerosis entails permanent compression of the labyrinthine liquid, for it fixes the base of the stapes

¹ Journal American Medical Association, October 7, 1893.

² Semaine Médicale, August 18, 1897.

in the fenestrum ovale without possibility of yielding in any direction. Atrophy of the stapedius muscle follows arthritis of the ossicles. The fenestra rotunda is itself sclerosed, rigid, and can no longer perform its compensatory functions. Suppurations of the tympanum may lead to a similar result. The pressure on the tympanum may be extrinsic, acting always through the medium of the tympanum (a plug of wax, a foreign body in the auditory meatus), and of the chain of bones and of the fenestra ovalis in lesions of the tympanum.

In other cases the lesion is in the labyrinth itself, but these cases are rare (exudations of blood or serum into the labyrinth, arterio-sclerosis of labyrinthine arteries, etc.). Under the influence of arterio-sclerosis, the tension augments in the arterial glomerules and in the labyrinth. Hence Bonnier thinks that the majority of cases of *vertigo ab aure lesa* are due to Bright's disease. Moreover, small miliary aneurisms forming on the arteries of the labyrinth in connection with atheroma are a fruitful cause of hemorrhage and of Ménière's disease.

As for the treatment of this disease, that by large doses of quinine (for which we are indebted to Charcot, who first formulated it from theoretical considerations) is now the most in favor, at least in the French hospitals. It has been a matter of frequent experience since Charcot first published the remarkable results which he had himself obtained from this remedy, that full doses of sulphate of quinine administered every day for two or three weeks produce a positive amelioration of all the symptoms. During the first few days of the treatment the head symptoms (the tinnitus and the vertigo) are worse, and the vertigo is so intense that the patient must be kept in bed to avoid the falls which he otherwise might receive. The medicine, too, is likely to upset the stomach, so that Gilles de La Tourette advises to prepare the patient by a milk diet before commencing the quinine treatment. It should be the aim to give the patient from seventy-five centigrammes to one gramme (ten to fifteen grains) during the twenty-four hours. This may be given in divided doses, or one-third of the daily quantity well diluted in water after each meal. At the end of eight or ten days the vertigo and tinnitus diminish, in many cases to completely disappear after a few days more of treatment.

Naturally many obstinate cases are only benefited, not cured, and in all a frequent return to the remedy after a period of suspension is necessary.

TWO POINTS OF VIEW.

THE striking differences of opinion or conclusions which may result from different points of view are well illustrated by certain points in the recent Opening Address of Dr. Roddick, the President of the British Medical Association, and the comments upon it of the *London Times*.

Dr. Roddick spoke, naturally, of the noble objects

of the Association, its impartial constitution, its accumulating capital, its great numbers of earnest men "pitted against false dogmas and ever battling for the truth." He alluded to the increasing power and usefulness in store for the Association in the future, and its benign and powerful influence for the amelioration and elevation of mankind.

"What must have been the President's feelings," writes the editor of the *Lancet*, "when he opened the *Times* of September 1st, to learn that all his eulogy of the Association and its power was a mistake, the truth being that the absence of such power and influence is one of the most remarkable characteristics of the organization, and one which has occasioned much perplexity to those who have been called upon to consider its proceedings."

The *Times* goes on to say that the Association has done nothing "either for the benefit of the medical profession or for that of mankind at all adequate to the apparent possibilities of the case," and that "probably no statesman was ever influenced by its views with regard to any matter of legislation, whether purely medical or relating to some one of the many social questions upon which medicine is calculated to throw light." The inadequacy of the Association's grants for scientific research is characterized by terming the grants "microscopic." The members at their annual meetings are said to prefer recreation to science, and all the work of the profession, whether scientific, charitable, or administrative, is said to be done by independent societies.

This characterization of the work of the Association, which, as no one adequately informed can deny, has been a potent influence for the benefit of medical and sanitary legislation and for medical science, is an excellent illustration of the effect of the false ideas which are engendered in the public mind by the spectacle of the want of organization and cohesion, the undignified squabbles of sections and coteries, the lack of united action, which, in the words of the *Lancet*, "are the weakness of the profession," and which are too apt to characterize the proceedings of large and complex medical associations. This, the unfortunate side of the work of such associations, is the one which attracts the attention of the public and the press, while the real, effective work quietly takes its place in the march of progress, and does not attract the notice of those who take a superficial view of the profession.

The inaccuracy of the assertions of the *Times* is evident enough to one who is familiar with the history of the Association, and we may refer our readers to an editorial on "The British Medical Association and its Work," in the *British Medical Journal* for September 11th, for a vigorous defence of the Association, and a recital of the numerous instances in which the work of the Association has resulted in great benefit to the British public and profession.

It is unfortunate that so wide a circulation should be given to a false and superficial view of the work of a great medical body, and it is unfortunate that there

should be anything in the proceedings of such a body, even though slight and comparatively unimportant, which should lend color to such statements as those of the *Times*. The British Association and the profession in Great Britain and elsewhere should endeavor to fortify itself against such aspersions by exhibiting no weak side to unfriendly critics, but with unity of purpose, organization and tenacity of effort, should work together for the advancement of the profession and of science.

MEDICAL NOTES.

THE PLAGUE is reported to be increasing in the Bombay presidency. Several Europeans have been attacked at Poonah.

FIRST AWARD OF THE MOSCOW PRIZE.—On the proposal of Professor Virchow the first Moscow prize, established by the municipality of Moscow and to be awarded at each recurring international congress, was bestowed upon Henri Dunant, the founder of the Red Cross Society, in recognition of his inestimable services to humanity.

YELLOW FEVER IN THE SOUTH.—The number of cases of yellow fever reported at New Orleans and along the Gulf Coast continues to slightly increase, but the death-rate is very low. There is no panic in Mobile or New Orleans, and very few are leaving either city. The quarantines continue to seriously affect the business of the railroads.

YELLOW FEVER IN CUBA is notably on the increase. All the fatalities so far have been among the Spanish soldiers. Dr. Caminero, stationed at Santiago, reports (September 4th) that the sick are taken to the hospitals in public conveyances without protest, and that a strange fatality seems to have seized even the unacclimated. He is to place placards on steamers running between Cuban and American ports warning against these public conveyances.

A BUREAU OF CLINICAL MEDICINE AND SURGERY.—There has been established at the Hall of the College of Physicians of Philadelphia, northeast corner of 13th and Locust Streets, a Bureau of Clinical Medicine and Surgery, having a central office with telephone connection, in charge of a clerk, whose duty it shall be to receive and post notices of the daily work in the various branches of surgery and medicine taking place at the different hospitals in the city. This is accomplished by notice to the bureau by postal card or telephone. By this means the numerous physicians who visit the city may be able to take advantage of the great clinical facilities offered by the hospitals of Philadelphia. A physician calling at the central bureau can thus ascertain what medical or surgical work may be going on during that day in any one of the different hospitals. The officers of the bureau are Roland G. Curtin, M.D., President; Henry R. Wharton, M.D., Secretary; Guy Hunsdale, M.D., Treasurer.

NEW ENGLAND.

THE NEW BUILDING OF THE TUFTS MEDICAL SCHOOL.—The new building of the Medical School of Tufts College was formally opened on September 27th. The exercises were held in the amphitheatre of the building, and consisted of an address of welcome by the President, Elmer H. Capen, of Tufts College, and an address by Dr. E. W. Cushing, Professor of Abdominal Surgery and Gynecology in Tufts Medical School. The new medical school stands on the corner of Shawmut Avenue and Rutland Street. The building was formerly the Free Will Baptist Church, but has been remodelled for its new purpose. It contains an amphitheatre, dissecting-room, bacteriological and chemical laboratories, library, museum, etc., and is provided with an elevator. A Dispensary is also provided for in the building.

NEW YORK.

SMUGGLERS OF PHENACETINE.—Special agents of the United States Treasury Department have recently arrested five or six men on the charge of smuggling phenacetine and trional into the country on steamers landing at Hoboken. The high duties on the drugs and the high prices which they command are given as the special inducements to this evasion of the customs laws.

YELLOW FEVER AT QUARANTINE.—There has been an arrival of yellow fever in the port of New York, but not from Louisiana or Alabama. The steamer *Finance*, which came in from Colon on September 22d had two cases of the disease on board, one of the patients being Patrick Keating (who was first attacked), and the other a passenger, John Endman, a medical student from San Jose, Guatemala. On boarding the vessel Health Officer Doty found both the cases comparatively light, and the patients doing well. They were transferred to the Quarantine Hospital on Swinburne Island, and the rest of the passengers and crew taken to Hoffman Island for observation.

CARBOLIC ACID AS A POISON.—On September 14th three women swallowed carbolic acid for the purpose of terminating their lives, and between August 13th and September 14th no less than fourteen persons, including the three mentioned, attempted suicide in this way in New York. In most of them the attempt was successful, and all but three of the unfortunates were females. The selection of this drug for the purpose, notwithstanding the agonizing suffering to which it gives rise, is supposed to be on account of the readiness with which it can be procured. No prescription is necessary to get it, and the pharmacist is simply required to label the bottle "poison" and preserve the name and address of the purchaser for future reference, should occasion arise.

MIDWIVES.—In regard to the failure of midwives to report their cases, while undoubtedly a large proportion of natural births are never reported, there

can be no question that this is the case with a still larger proportion of still-births. This is clearly shown by the statistics of the Board of Health. Thus, in a given period 24,134 natural births were reported by physicians, and 22,770 by midwives. Yet in the same period, while 2,262 still-births were reported by physicians, only 1,034 were reported by midwives. The incompetence of the midwives is illustrated by the fact that large numbers of women die in New York from the occurrence of abnormal and unusual circumstances attending childbirth. In a large proportion of these the conditions are such that no ignorant attendant can foresee the danger, and there can be little doubt that many of these lives could be saved if midwives were compelled to possess an adequate knowledge of obstetrics.

THE NEW RECREATION PIERS.—On September 25th the second of the new recreation piers for the people was officially opened by Mayor Strong. There were also addresses by other speakers, and a band of music played until ten o'clock. This pier is located on the East River at the foot of Twenty-fourth Street, two blocks below Bellevue Hospital. It is of immense size, being 722 feet in length, and capable of accommodating 12,000 persons. Its completion is, of course, rather late for the present season, but it will be all ready for the beginning of next summer's heat. In the meanwhile it is proposed, if the necessary funds can be secured, to enclose this and the East Third Street recreation pier in glass, and turn them into winter resorts for the poor. In favor of this plan it is urged that the plants required for the adornment of these large winter gardens can be had not only without expense, but as a positive saving to the city. The various exotics which are in the parks during the summer have to be stored in greenhouses in the winter, and as the capacity for this purpose on city property is limited, quite a large amount has to be paid each year for outside storage. If, then, the piers are properly equipped as winter gardens all this storage expense can be saved.

A PHYSICIAN APPOINTED TO THE BOARD OF CHARITIES.—For the first time a physician has been made a member of the Board of Public Charities, and the measure meets with the general approval of the medical profession. On September 21st Mayor Strong appointed Dr. Stephen Smith, the well-known surgeon, a Charities Commissioner, to fill the vacancy made by the resignation of Commissioner Croft. At the time the last two vacancies occurred the mayor expressed the opinion that it was not good policy to give positions on the board to physicians, but he has now evidently seen fit to change his views on the subject. Dr. Smith was graduated from the College of Physicians and Surgeons, New York, in 1850, and afterwards became resident physician at Bellevue Hospital. In 1853 he was made editor of the *New York Journal of Medicine*, and in 1854 attending surgeon to Bellevue Hospital. In the latter capacity he has served ever since, and his surgical writings

have enjoyed a wide popularity. During the late war he published a hand-book of surgery for field use, which was officially adopted by the Surgeon-General of the United States Army. When the Metropolitan Board of Health was organized, in 1866, he was, with the late Dr. Willard Parker, on the first Board of Commissioners. Dr. Smith served for a time on the State Commission in Lunacy, and for the past four years has been a member of the State Board of Charities. With his varied attainments and extensive experience he is therefore especially well qualified for the position of Charities Commissioner, and his accession to the management of this important department will no doubt add greatly to the efficiency of the board.

Miscellany.

BACTERIOLOGY RUN MAD.

THE following extract is taken from an English paper:

The Berlin correspondent of the *Standard* telegraphs over this great discovery by a German professor: "Professor Marpmann, of Leipzig, has recently examined 67 kinds of ink, such as are used in schools, and has arrived at results which show that it may, under certain circumstances, be dangerous to wound oneself with an inky pen. Most of the inks he examined were made of gall-nuts, and contained a large quantity of micrococci, bacteria and fungi. One sample, made of nigrosine, an aniline pigment, and taken from a newly-opened bottle, also contained quantities of fungi and bacilli. From a red and blue sample the professor cultivated bacilli which killed a mouse in four days; but they were taken from bottles which had been opened for three months."

"Is there any known substance, we wonder," says the *Westminster Gazette*, "in which a German professor could not cultivate a bacillus which would kill a mouse in four days? It seems to us rather creditable to the mouse to have lived four days. The moral is, Don't drink ink, or wipe your pen on your lips. The temptation to do these things is so besetting that these cautions ought to be widely disseminated. By dint of great determination we have ourselves resisted the impulse to take a draught of ink in the early morning."

METEOROLOGICAL RECORD

For the week ending September 18th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,945: under five years of age 1,257; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 625, consumption 279, acute lung diseases 188, diarrheal diseases 430, diphtheria and croup 71, typhoid fever 62, whooping-cough 19, cerebro-spinal meningitis 16, scarlet fever 10, malarial fever 8, measles 8.

From whooping-cough New York 6, Chicago, Pittsburg and Washington 3 each, Brooklyn 2, St. Louis and Boston 1 each. From cerebro-spinal meningitis Washington 5, Boston 4, New York 3, Baltimore, Lynn, Malden and Fitchburg 1 each. From scarlet fever New York 5, Baltimore, Pittsburg, Fall River, Lowell and Cambridge 1 each. From measles Pittsburg and Providence 3 each, New York 2. From malarial fever New York and Brooklyn 4 each. From erysipelas Baltimore 1.

In the thirty-three greater towns of England and Wales with an estimated population of 10,922,524, for the week ending September 11th, the death-rate was 19.4. Deaths reported 4,089, diarrhea 671, whooping-cough 78, measles 65, fever 52, diphtheria 48, scarlet fever 31.

The death-rates ranged from 8.2 in Halifax to 35.3 in Preston; Birmingham 22.2, Bradford 22.8, Croydon 9.5, Gateshead 22.7, Leeds 23.3, Leicester 23.6, Liverpool 26.9, London 16.3, Manchester 23.6, Newcastle-on-Tyne 23.0, Nottingham 19.9, Portsmouth 14.0, Sheffield 26.1, Sunderland 22.7.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 18, 1897, TO SEPTEMBER 24, 1897.

The leave of absence granted LIEUT.-COL. JOHNSON V. D. MIDDLETON, deputy surgeon-general, chief surgeon, Department of California, is extended one month.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 25, 1897.

C. E. RIGGS, assistant surgeon, detached from the New York Navy Yard, October 4th, and ordered to the "Newport," October 4th.

J. F. LEYS, passed assistant surgeon, detached from the "Helena," September 20th, and ordered to the "Vesuvius."

N. H. DRAKE, surgeon, ordered to the "Minneapolis," "Columbia" and other vessels in reserve at League Island, Pa.

M. F. GATES, passed assistant surgeon, detached from the "Minneapolis," on relief, and ordered to the Boston Hospital.

G. P. LUMSDEN, surgeon, detached from Port Royal, on relief, and ordered to special duty attending officers at Norfolk, Va.

G. A. LUNG, passed assistant surgeon, detached from the Boston Hospital, on relief, and ordered to Naval Station, Port Royal, S. C.

M. S. GUEST, passed assistant surgeon, detached from the "Vesuvius" and ordered to the "Helena," September 20th.

F. RODGERS, surgeon, when detached from Boston Navy Yard, ordered home and be ready for sea.

H. E. AMES, surgeon, ordered to the Navy Yard, Norfolk, Va., October 2d.

M. S. ELLIOTT, assistant surgeon, detached from the "Indiana" and ordered to the "Porter."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING SEPTEMBER 18, 1897.

SAWTELLE, H. W., surgeon. To proceed to Atlanta, Ga., for special duty. September 15, 1897.

CARTER, H. R., surgeon. To proceed to New Orleans, La., for special duty. September 14, 1897.

BANKS, C. E., surgeon. To proceed to Baltimore, Md., for special duty. September 13, 1897.

GLENNAN, A. H., passed assistant surgeon. To proceed to Mobile, Ala., for special duty. September 15, 1897.

MCINTOSH, W. P., passed assistant surgeon. To represent Service at meeting of Mississippi Medical Society at Louisville, Ky., in October. September 17, 1897. To proceed to Memphis, Tenn., and assume temporary command of Service. September 18, 1897.

GUIERAS, G. M., passed assistant surgeon. To report to Surgeon H. R. CARTER for special duty. September 17, 1897.

GEDDINGS, H. D., passed assistant surgeon. To proceed to Jackson, Miss., for special duty.

RUSSELL, H. C., assistant surgeon. Granted seven days' leave of absence from October 15, 1897. September 16, 1897.

SOCIETY NOTICES.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.—The next regular meeting will be held at the Medical Library, 19 Boylston Place, on Wednesday, October 6th, at 12 M.

The following papers will be read:
Dr. B. H. Hartwell: "Contre Coup; Its Relation to Injuries of the Head."

Dr. F. J. Canedy: "The Homicide of Mrs. Hattie McCloud at Shelburne Falls on January 8, 1897."

Dr. J. G. Pinkham: "Was it Murder or Accident?"

Members of the medical profession are cordially invited.

JULIAN A. MEAD, M.D., Secretary.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—The twenty-third annual meeting of the Association will be held at Louisville, Ky., October 5-8, 1897.

THOS. HUNT STUCKY, President, Louisville.
H. W. LOEB, Secretary, St. Louis.

BOOKS AND PAMPHLETS RECEIVED.

A Case of Primary Sarcoma of the Pleura. By F. G. Finley, M.D., and W. I. Bradley, M.D., Montreal. Reprint. 1897.

The Pelvic Viscera in Relation to Micro-Organisms in Health and Disease. By J. C. Webster, M.D., F.R.C.P.E., F.R.S.E., Montreal. Reprint. 1897.

Remarks on Two or Three Points on the Technic of the Operative Treatment of Acute Appendicitis. By George E. Armstrong, M.D., Montreal. Reprint. 1897.

The Nature of the Leucocytosis Produced by Nucleinic Acid; A Preliminary Experimental Study. By Delano Ames, A.B., M.D., and A. A. Huntley, M.D., Baltimore. Reprint. 1897.

Lectures on the Action of Medicines, being the Course of Lectures on Pharmacology and Therapeutics delivered at St. Bartholomew's Hospital during the Summer Session of 1896. By T. Lauder Brunton, M.D., D.Sc. (Edin.), LL.D. (Hon.) (Aberd.), F.R.S., Fellow of the Royal College of Physicians; Associate Fellow of the College of Physicians of Philadelphia; Honorary Member of the Pharmaceutical Society; Physician and Lecturer on Pharmacology and Therapeutics to St. Bartholomew's Hospital. New York: The Macmillan Co. 1897.

Original Articles.

PHYSICAL TRAINING, ITS FUNCTION AND PLACE IN EDUCATION.¹

BY EDWARD MUSSEY HARTWELL, PH.D., M.D.,
Director of Physical Training in the Boston Public Schools.

ABRAHAM LINCOLN once characterized the slavery question as "a durable question." In the history of education the question as to the legitimate place and standing of physical training has assuredly proved itself a durable question, since in a certain sense the history of education may be regarded as the history of a series of attempts on the part of thinkers and teachers to reconcile the claims of bodily and mental training in the up-bringing of children and youth. In times past and in our own time physical training has been exalted, tolerated, neglected or contemned, in varying degrees, according to the character of the conceptions concerning the nature of the human body and of its relations to the human mind, which have exerted a dominant influence upon those charged with the shaping of educational policy and the administration of educational affairs.

Popular education is to all intents and purposes a modern invention, and opinion is still somewhat divided as to its value and efficiency. The difficulties in the way of organizing public education on a thoroughly satisfactory basis have been enhanced and multiplied, — owing to the inextinguishable predilection of the nineteenth-century man for city life. Urbanization has proceeded so rapidly throughout Christendom that elementary education in the near future is likely to relate chiefly to the training of city-bred if not city-born children. Already in our own State more than 60 per cent. of the school population is found in towns having at least 10,000 inhabitants. As a result of urban crowding, not to mention other causes of disquietude in the public mind, the durable question as to the meaning and value of physical education is becoming more insistent and urgent than ever before. I believe that the most convincing answer to this as well as to certain other fundamental educational questions which I will not take time to specify, is to be found in the teachings of modern medical science, and of the biological sciences, which are the offspring of medicine. I believe also that the time is approaching when the medical profession can exercise, if it will, not only a large but a decisive influence towards the improvement of education by defining the limits and relations of mental and bodily training. Because I believe these things I shall direct my remarks this evening mainly to the consideration of the meaning of education in general, and of physical education in particular, in the light of the modern doctrine of the human body.

The doctrine of the human body current among scientific men is one of the most notable and significant achievements of the modern spirit. It has been wrought out and developed during the past two centuries and a half, and owes its characteristics of comprehensiveness, suggestiveness and illuminative power to the improvement and consolidation of the physical sciences, particularly of those which we term the biological sciences. Mr. Huxley has called attention to the essential solidarity and kinship of these sciences,

and to the genetic relation between them and medicine, which, till within very recent times included "what little physical science could be seen to bear directly upon human life."

"It is a peculiarity of the physical sciences," he says, in his address on "The Connection of the Biological Sciences and Medicine," "that they are independent in proportion as they are imperfect; and it is only as they advance that the bonds which really unite them all become apparent."

Through the advance alluded to by Mr. Huxley man's knowledge of himself has been immensely increased, and his conception of nature and of his place in nature radically changed. The human mind has been thereby both uplifted and enlarged. Considered simply as a member of the animal kingdom, man is a much more intelligible and interesting creature than ever before, since so many new and commanding points of view have been established from which his structure and powers and the laws governing the development and use of his powers may be studied profitably.

The individual human being begins as one of the simplest of animal mechanisms. Microscopic in size, its parts are indistinguishable or few at the most; its functions are reduced to lowest terms; its habitat is restricted to a particular seat in a single organ of its mother; and its condition is that of a dependent parasite, without intelligence, responsibility, or recognized legal status. It evolves gradually and surely, by duly ordered and progressive stages, into a bulky organism, goodly in size and symmetry, having parts beyond counting, whose arrangement is bewildering in its marvellous complexity; with functions so varied and specialized and co-ordinated that it is enabled to play the part of an intelligent, self-sufficing, individual member of society, free to range throughout the world as an independent citizen of the same, having legal rights and moral responsibilities as an heir of all the ages, and as such entitled to an indefeasible share in mankind's hopes of immortality. It begins its career at the level of the ameba and the wandering white-blood corpuscle; when it emerges from immaturity at the summit of a long series of spiral changes and enters upon its inheritance and is made free of the world as a matured and perfected human being, it has become man, and well deserves to be characterized in the words which Shakespeare puts into Hamlet's mouth as "the paragon of animals, the wonder of the world."

In general terms the modern doctrine of the human body is based upon two leading ideas, namely, (1) that the organism is an aggregation of matter which, by reason of the arrangement of its parts, and of the qualities of the living substance composing those parts, is capable of transforming and utilizing energy, that is, it is a living machine for doing work; (2) that the adult body is the product of organic evolution to the outworking of whose laws it owes its rank among organisms and its efficiency as an individual organism.

As affirmations of the modern doctrine of the human body, which bear more or less directly on our subject, the following may be cited:

(1) The adult body is the highest term in the series of animal mechanisms found in the world to-day, since in it we find the most elaborate and perfectly co-ordinated subdivision of labor associated with the greatest differentiation of structural parts and the highest specialization of functional powers.

(2) The human body is the highest term in the whole

¹ This paper has been re-written in a measure, since it was read before the Boston Society for Medical Improvement, November 16, 1896.

series of living mechanisms produced by organic evolution in the vast stretch of time since the first and simplest of living things appeared upon the earth.

(3) Every adult human body is the highest term in a long series of orderly, progressive developmental phases, which taken together constitute the period of its immaturity. This period may be divided for convenience into stages, namely, (1) Embryonic, (2) Fetal, (3) Infantile, (4) Childhood, and (5) Adolescence.

(4) At the culmination of each of its developmental stages the body of the human being more or less resembles the highest stage of zoological development attained by certain of its lowlier, less intelligent and responsible animal kindred.

(5) As in the zoological series of developed organisms, each well marked advance is characterized by greater differentiation of parts, higher specialization of function, and more elaborate subdivision of labor; so in the embryological series of developmental stages through which the body is transformed from a unicellular ovum into a communal mechanism, made up of somatic or general and minor or special mechanisms, each stage of development is signalized by the acquisition of more numerous and more perfectly adapted and co-ordinated parts; by an increased efficiency of general functions and the addition of special aptitudes and powers; and by the attainment of larger and more varied capacity for improvement and training in the exercise of its distinctively human endowments.

(6) In acquiring structural completeness and functional perfection the human body recapitulates in a condensed or schematic way the development of its ancestral forms, first, of its simplest, lowliest and most ancient; last, of its most highly developed, most gifted, and recent. Its period of immaturity, during which it may be moulded and educated, is more prolonged and diversified and therefore more fateful and important than the period of immaturity either of its ancestors or its nearest kindred in the animal series.

The jurisdiction of the laws of evolution over mental as well as bodily development is pretty generally conceded, even in strongholds of orthodoxy so-called. The following extract from Drummond's "Ascent of Man" which consists of lectures originally delivered before the Lowell Institute in this city, is highly significant, considering its source.

"Mind in man, does not start into being fully ripe. It dawns; it grows; it mellows; it decays. This growing is a gradual growing, an infinitely gentle, never abrupt unfolding, — the kind of growing which in every other department of nature we are taught by nature to associate with an evolution. If the mind of an infant has been evolved, and that not from primeval man, but from some more ancient animal, it could not to more perfection have simulated the appearance of having so come. But this is not all: the mind of a child not only grows, but grows in a certain order. And the astonishing fact about that order is that it is the probable order of evolution of mental faculty as a whole. The mind of a child is to be treated as an unfolding embryo; and just as the embryo of the body recapitulates the lifelong history of all the bodies that lead up to it, so this subtler embryo in running its course through the swift years of early infancy runs up the psychic scale through which mind probably evolved. We have seen also that in the case of the body each step of progress in the embryo has its equivalent, either in the bodies or in the embryos of lower forms of life. Now each phase of mental development in the child is also permanently represented by some species among the lower animals, by idiots, or by the mind of some existing savage."

If we admit the declaration of modern science that the laws which determine the orderly progress of the cells, tissues and organs of the human body from a general and simple to a differentiated and special state also bear sway, *pari passu*, throughout the realm of

the human mind and over all the products of human intelligence and culture, can we avoid the conclusion that education, which avowedly aims at enabling the un-grown human being to make the ultimate utmost of himself, should conform its measures and methods to nature's laws of growth and development?

Pedagogical oratory and literature teem with assertions that education means educating, unfolding — evolution. But no very searching investigation is needed to discover that educationists hold very largely to the very doctrine of evolution that has been discredited and displaced by more modern science.

What we call "cramming" is, as an educational procedure, merely a short-sighted deduction from the principles of what used to be termed "evolution," as opposed to the doctrine of epigenesis. Education by "conveying information" resembles the process by which a gardener develops a small onion into a plump, marketable onion. Both processes are in harmony with the idea that the immature organism is a perfect edition in miniature of the adult, and that evolution consists in the growth of small parts, originally created perfect, into larger and finally full-sized parts through the intussusception of aliment.

This view of evolution, which was dominant till microscopical research showed it to be incorrect, was summed up by Haller, the great authority of the last century in biological science, as follows: "There is no becoming; no part of the body is made from another, all are created at once."

William Harvey's statement in the seventeenth century of the doctrine of epigenesis is as follows: "The first concrement of the future body grows, gradually divides, and is distinguished into parts; not all at once, but some are produced after others, each emerging in its order." This view, which was rejected by the evolutionists of the eighteenth century, has been accepted as a corner headstone by the evolutionists of the nineteenth.

The body as a whole is a communal structure, a sort of federal union of tissues and organs. Among machines it resembles an army or a city, rather than such mechanisms as an eight-day clock or a windmill. "Of this army," says Huxley, "each cell is a soldier, an organ, a brigade, the central nervous system headquarters and field telegraph, the alimentary and circulatory system the commissariat."

In general terms, it may be said that the principal minor mechanisms found in the human body largely subserve the interests of the organs devoted to the performance of voluntary purposive mechanical work, namely, the muscles.

It is the skeletal muscles and the skeleton, then, which constitute the executive working machinery of the body. It is important to remember that a "muscle" is fundamentally a muscle and a nerve besides.

The muscular and nervous tissues have been well termed "the master-tissues." All other tissues, omitting the indifferent and supportive tissues and the reproductive tissues, may be classed under the head of "tissues of digestion," or "tissues of excretion." In other words, the neuro-muscular system has two sets of servants which play the parts of "purveyors" and "scavengers," respectively.

What may be termed the gross-income fund of energy of the bodily community is derived chiefly from the productive activity of its purveyor members. It is pre-eminently the function of the master-tissues to turn

the net-income of the body to the fullest and best account as active energy; which net-income is what remains from the gross-income after the fixed charges for construction, maintenance and repair have been met. To secure a wise expenditure of net-income, therefore, it is needful to prevent the master-tissues from developing aimless, blundering or spendthrift habits of action. Prevention, in this instance, can be only secured through the intelligent and adequate training of the neuro-muscular system. If the development of ability to make intelligent and adequate use of the net-income of man's free energy be the main end of his education, it is clear that neuro-muscular education, or physical training, must constitute a considerable part of the measures directed to that end.

The primary, essential, universal factor in all forms of physical training is neuro-muscular exercise. The ends of exercise may be characterized, in a general way, as, first, the promotion of health, and, second, the formation of proper habits of action. The one is a hygienic end while the other is a distinctively educational end.

The main field of education is the nervous system, and the principle of all forms of education into which motor training enters as a factor are based upon the power of the nervous system to receive impressions and to register them or their effects; in other words, upon its ability to memorize the part it has played in acquired movements, and on occasion to revive and repeat such movements.

The student of nervous disorders notes carefully the peculiarities of his patient's movements in order to determine the seat of his injury or weakness and the nature and extent of his disease. It is equally necessary that the practical teacher should apprehend the significance of the spontaneous and acquired muscular movements of his pupils, be those movements coarse or fine; since those movements constitute an index of the action of the brain which it is the teacher's business to develop and train, and also serve to measure the success and test the character of the teacher's efforts at instruction.

The motor element in education is so large and of such vital importance that we hazard little in predicting that the systematic study of movements is destined to play a much more prominent part than has been accorded it hitherto, in the professional training of all classes of teachers.

As regards their regional relations, our bodily movements may be characterized as central or peripheral.

"By a central movement," says Mercier, in his "The Nervous System and the Mind," "is meant, generally, a movement of the trunk. By a peripheral movement is meant, generally, a movement of the digits, mouth or eyes; and the remaining parts of the body are classed in an intermediate position, and in one which approximates to the central or to the peripheral, according, generally, to the size of the part moved, and the size and individuality of the muscles concerned in the movement. . . . The movements here called central are continuous in duration, vague in limitation, few in number, same in character, and form a general, approximate or coarse adjustment. Progress toward the periphery brings us to movements that are more intermittent in duration, more precisely defined, more numerous, more diversified, and more specially adapted to particular ends; and, when at the eyes, the articulatory apparatus and the digits, we reach the extreme periphery, all these characters reach their highest degree of development."

In the evolution of the race and of the individual, the more general functions and organs are formed and developed earlier than the special functions and their organs; for example, the circulatory and alimentary organs develop earlier than the vocal organs and the hands and feet. The same law obtains likewise in the growth and development of the nervous system, both as to its massive and its minute parts. The nervous mechanisms concerned in central movements are at once older and more lowly placed than the mechanisms concerned in peripheral movements. To those parts of the nervous system, in man, which are formed earliest and are practically completed and fully organized at birth, the late Dr. Ross, a leading English neurologist, gave the name "fundamental," while he designated as "accessory" those parts which are rudimentary at birth and comparatively late in their growth and development. Broadly speaking, central movements are "represented" in low-level, fundamental centres, and peripheral movements in high-level, accessory centres. If, as has been stated, the nervous system is the field of education, education to be natural, safe and effectual should defer the training of the accessory parts of the nervous system until the development of its fundamental portions has been secured by appropriate forms of general training. Is it too much to ask that educationists should recognize, ponder upon, and be guided by the laws of development which determine the health and power of the brain-centres, and the health and efficiency of the servants and ministers of those centres, namely, the skeletal muscles?

The law of the evolution of the nervous system seems to me a sure and serviceable criterion of the worth and propriety of educational procedures of every kind, since it affords a means of comparing our conventional methods of educating the individual with nature's method of educating the race.

Our "earthly pilgrimage" embraces three stages, namely, (1) that of Evolution or Immaturity, which is *par excellence* the period of growth or increase in size, of development or improvement and increase of functional powers, and of storage of energy; (2) that of Maturity or Completed Development, in which growth and development proceed more and more slowly till they cease, — a period of productive activity, of balanced income and expenditures of energy; and (3) that of Dissolution or Decline, marked by excess of expenditure of energy, by weakened and decaying functions, and by wasting and degeneration of organs and tissues.

Growth and development characterize the stage of immaturity, as has been said, but since development waits upon growth, the two processes vary in amount and rate in different parts of that stage, considering the body as a whole. Nor should it be forgotten that the several somatic and special mechanisms of the body differ in respect to the order and rates of their growth and development. If the education of children and youth shall ever become thoroughly natural and rational, it will be because the significance of that order and rate, and their relations to life and death, are recognized and heeded to an extent that is nowhere common as yet.

The stage of evolution or immaturity is of paramount importance, since the formal education of the vast majority of the pupils in our elementary and secondary schools ceases long before maturity is reached.

This stage may be roughly divided into three equal periods of eight years. Both growth and development proceed during each period, but growth preponderates in the first and second, and development in the third period. The salient features of each period may be grouped as follows:

First Period.—From birth till the close of the eighth year. The whole body grows rapidly in the first two years of life, more particularly in the first year, but it is the "immense" growth of the brain—which attains its full weight within a few ounces in the eighth year—that signalizes this period most markedly. In the domain of development the sensory organs take the lead and reach a high degree of perfection, though certain of the most essential neuro-muscular mechanisms concerned in the co-ordination of relatively central movements also undergo active development, for example, those concerned in equilibration, locomotion and vocal utterance. The child is imitative, inquisitive and acquisitive; but his perceptive powers and his memory develop faster than his powers of discrimination and expression. During this period sensory education may safely be diversified and somewhat specially emphasized; but motor education should be of a more general and elementary character.

Strenuous and exacting "drill," especially of the intermediate and accessory mechanisms, is contra-indicated for the child. Both games and gymnastics yield valuable results if they are intelligently selected and conducted; but the first should be easy and simple, and the second elementary in their character.

Second Period.—From the beginning of the ninth to the end of the sixteenth year. This is distinctively the period of most rapid growth in height and weight. In increase of weight the muscles play the leading part. Motor co-ordinations reach a higher degree of development than was possible during the preceding period, though they are not fully perfected till adolescence is nearly completed. "The process of perfecting motor co-ordinations cannot be said to be complete," says Dr. Clouston, "while the awkward, ungraceful motions of hobbledohoyhood last, and until we reach the grace and poetry of body-motion of the maiden of twenty-three, and the dexterity, force and swiftness of co-ordination of eye, hand and body seen in the male cricketer or lawn-tennis player of five and twenty. As Dr. Clouston has pointed out, one of the most marked features of this period is the co-ordination of motion and emotion.

In this period the individual diverges from the neutral condition of childhood and takes on the distinctive characteristics of youth or maiden. The change in body, mind and character which result from the establishment of puberty are profound and lasting in both sexes, though in this period they transpire more rapidly and proceed further in the gentler sex.

Self-consciousness is awakened, self-confidence is quickened, and new impulses, appetencies and ambitions arise which prompt the adolescent to try all things and everybody. The child yields to authority and accepts dicta with comparatively good grace; but the youth demands reasons and must be convinced, or at least persuaded, by his teachers and governors.—he may be led, but he resists being driven. Educational methods, therefore, particularly during the second-half of this period, should savor more of incitement than compulsion. The formal education of the great major-

ity of public-school pupils terminates in this period, since so soon as they are fairly well grown their services become marketable. Those who are destined to the ruder forms of labor or the humbler crafts and occupations enter the lowest ranks of wage-earners, while as yet the privileged youth selected by their parents or by circumstances to engage in pursuits which demand special aptitudes or technical training are too undeveloped, in most instances, to make rational choice of a vocation, and much less to engage in professional pursuits or the higher crafts.

On the whole, since the period of most active growth appears to be followed by one of comparative exhaustion, when the organism is peculiarly susceptible to disturbing and deterrent influences, the second may be considered, from the hygienic standpoint, as the most critical of our three periods. Exhausting constitutional disease, excessive mental or bodily exertion, under-feeding, ill-judged deprivation of muscular exercise, may readily lead to irremediable stunting or enfeeblement, especially in those who are city-born and city-bred. If physical education be neglected or misdirected during this period, if it be deferred to a more convenient season, it cannot accomplish its perfect work, either as regards the promotion of health or the development of the motive powers of the brain.

The main general department of physical education should be systematically availed of, that is, both gymnastic training and athletic pastimes should be given a prominent place in the school curriculum, and the forms of exercise selected should be more varied, complicated and difficult than those employed in the previous period. But the time for engaging in feats or contests that demand extraordinary strength, endurance, or skill is not yet.

Third Period.—From the beginning of the seventeenth to the close of the twenty-fourth year. This, the period of established adolescence, is distinctively a period of development—of development of character as well as of bodily and mental faculty. The life of the race begins to be reflected in the life of the individual—to whom a higher and wider range of activities is opened through the development and perfecting of his higher fundamental and accessory neuro-muscular mechanisms. Emotion is co-ordinated with self-chosen aims and ideals; self-directed actions increase in number and effectiveness; and the individual is prepared by special forms of technical training to enter upon his lifework as an adult, independent member of society.

The muscles, which are to serve as the executive instruments of the brain, do not attain full growth till towards the end of the second period. Then, when both brain and muscles are fully grown, neuro-muscular development enters upon its most active and important stage, that is, in the third period. Measures that directly promote growth are mainly hygienic measures, and measures that directly promote development are mainly educative. An intelligent combination of hygienic and educative measures is called for, both in the sensory and motor education of the individual, during each and all of the three periods; but as regards physical education during the whole of the first and the first half of the second period, hygienic forms of exercise should preponderate, while during the last half of the second and the whole of the third period educative forms of exercise should be assigned the leading part,—provided that practically normal

growth and sound health have been secured to start with.

Attempts at *tours de force*, trophy winning, and record breaking, which would be ill-judged at an earlier stage, may now be profitably encouraged — within reasonable limits — in the case of well-developed and well-trained gymnasts and athletes. Doubtless there are valid objections to be urged against rampant athleticism. Nevertheless, the predilection of collegiate youth for athletic sports and contests may be justified as natural and fitting by the teachings of neurology and psychology, if once it be admitted that the development of mind and character, as well as that of the brain and muscles, is subject to the laws of evolution. The average collegian, if a healthy animal, is apter at expressing himself fully in terms of muscularity than in terms of mentality. Intellectual maturity comes later, — unless arrested development supervenes. It can hardly be considered a misfortune that, in the hey-day of youth, the sons of civilized men tend to exhibit in their games something of the hardihood, daring and contentiousness which characterized the principal pursuits of their primitive, beast-hunting, war-making ancestors.

Modern education presents many vestigial features that bear witness to its descent from medieval and ancient origins. Of old, when the learned class was made up chiefly of readers to whom was given the name of clergymen, the church enjoyed a natural monopoly of education in its technical sense. The church's claims to authority were based on written documents. Most of the world's books belonged to churchmen, or had been written by churchmen. Naturally enough the clergy became the recognized teachers of the literary arts of expression and interpretation, and were inclined unduly to exalt those arts at the expense of the painful, objective study of Nature and of Man.

Though the control and conduct of educational affairs has been secularized in a large measure, the inner purpose and guiding principles of elementary and secondary education are still strongly tinged by antiquated conceptions and scholastic dogmas regarding human nature and the means of influencing and developing it. The unwillingness of many educationists to accord science a co-ordinate place in the scheme of liberal education, and the general indifference, not to say aversion, of the responsible managers of popular education to the just claims of bodily training, are forcible reminders of the strength and vitality of traditional views and conventional methods.

The medical profession, by its revolt against the tyranny of speculative philosophy and theological dogmatism, has succeeded in securing freedom of thought and teaching within its own domain. It has thereby rendered important service to the cause of superior education. It would seem that the opportunity for the medical profession to exercise a wise and helpful influence upon popular and secondary education — particularly in respect to school hygiene and physical training — grows constantly larger and more inviting. Educationists as a class apprehend but feebly the teachings of modern science with regard to the interdependence of mind and body. To whom should they more appropriately turn for light and leading than to the leaders in medicine, who have done so much for the enlightenment and improvement of mankind?

Among the medical sciences neurology, by reason of

its teachings concerning the nature and functions of the neural and neuro-muscular mechanisms, bears most directly upon educational theory and practice. Laurie, a well-known Scotch writer on education, has put forth a serviceable statement of the modern ideal of education. "By education," he says, "we mean the training of a man with a view to make him all that he can become. . . . The education of a child is the bringing of him up in such a way as to secure that when he is a man he will fulfil his true life, — not merely his life as an industrial worker, not merely his life as a citizen, but his own personal life as a citizen through his work and his citizenship." And he goes on to say that the attainment of the ethical end of education must be considered "from the point of view not only of the growth of mind, but of the growth of body; for we have not to train up a soul, says Montaigne, nor yet a body, but a man, and we cannot divide him."

How inadequate and ill-adapted the old neurology was to serve as a rational basis for the modern civic ideal of education may be guessed from the following extract from Prochaska's "*De Functionibus Systematis Nervosi*," written more than a century ago:

"We have disputed strictly enough whether the soul be matter or brain; whether thought to be an electric fire or a movement of the vital spirits; whether souls form their bodies; whether they are diffused through them, or dwell only in the head; whether souls and bodies exercise a real or ideal influence on each other; whether an instinctive impulse or a passion belongs to the body or the soul; or whether the vital spirits be elastic or inflexible, electrical or ethereal, etc. All these inquiries will remain forever inscrutable mysteries, and do not belong to our subject; they can remain altogether uninvestigated without any disadvantage to the real usefulness of theoretical medicine, but we have pursued them with profless diligence, and have done our best to confuse them more and more. How much have we effected in resolving questions useful to our art, as, for example, in determining by what laws the mind moves the machinery of the animal organism? Under what circumstances the nerves excite sensation? Under what the sensation becomes an animal moving force, so as to move this or that limb in such a manner and not otherwise? After what laws the imaginations, the conceptions of the understanding, pleasure, pain, the instincts, the passions and the will impel various portions of the animal to perform the actions intended by the Creator in uniting the machine with a thinking force?"

Contrast with the above the following statements of modern neurological doctrine taken by way of illustration and almost at random:

While the physical function of the nervous system is the redistribution of force, mainly by the production and regulation of muscular action, the psychological function of this system is mainly the production of muscular movements. . . . Briefly, the study of the psychological functions of the nervous system is the study of conduct. [Mercier — *The Nervous System and the Mind*.]

The "nerve-centre" of mammalia and of man is a collection of nerve centres, — variously organized through past excitations, yet still variously organizable by excitations, to come. To-day the state and disposition of organs and of the organism are the product of the past immediate and remote, individual and ancestral. To-morrow and in the distant future they will become what they may be made to become by training, by education, and by new conditions of life. [Waller's *Physiology*.]

The order of the development of the nervous system in the race has been from the fundamental to the accessory portions; and no one can reverse this process with impunity in that further development of the individual which consti-

routes education in its widest sense. [Ross — *Diseases of the Nervous System*.

A special part of the nervous system, that which we know as the central nervous system, the brain and spinal cord, is supreme among the nervous tissues and is master of the skeletal muscles as well as of the rest of the body. . . . The word "training" suggests the reflection that the physiological interpretation of becoming easy by practice is that new paths are made, or the material of old paths made more mobile by effort and use. . . . We must suppose that training promotes the growth and molecular ability of the motor area and of all its connections. [Foster — *Text-Book of Physiology*.

All human education aims at the control of inherited and acquired reflexes through intelligent and reasonable motives. [Kussmanl — *Störungen der Sprache*.

Education consists in modifications of the central nervous system. . . . In the development of the central system it is found that an anatomical framework is first formed. In this framework are represented in outline the nerve structures whose functions are most fundamental. These with later growth are locally strengthened and organized, and by the establishment of associative paths gain both a wider influence and a greater complexity of reaction. . . . Education must fail to produce fundamental changes in the nervous organization, but to some extent it can strengthen formed structure by exercise, and in part waken into activity the unorganized remnant of the dormant cells. No amount of cultivation will give good growth where the nerve cells are few and ill-nourished, but careful culture can do much where there are those with strong inherent impulses towards development. [Donaldson — *The Growth of the Brain*.

It were idle to assert that the modern doctrine of the human body admits of final and complete statement. It is equally idle to deny that the salient teachings which are embodied in that doctrine are too little heeded in the nurture and admonition of the rising generation. The teachings and implications of modern neurology are, I submit, sufficiently clear and definite to warrant the claim that physical training, by reason of its neuromuscular element, lies at the basis of human education, and of necessity enters into and interlocks with what for convenience is customarily termed mental and moral training. By physical training I mean the more or less regulated practice of some form of "muscular exercise," under such conditions as serve to promote the health of the organism or to develop and discipline its motor functions, either in a general or a special way.

Viewed in the light of the modern doctrine of the human body, the office of the teacher of youth, be he a teacher of morals, of literature, or of gymnastics, possesses a new and heightened significance. Though education as at present organized is largely traditional in its aims and mechanical in its methods, there is increasing reason to hope that it will be transformed by the modern spirit till it shall become a science based upon the science of human nature, and shall cease to be an empiric art, mainly shaped and ruled to accord with the dreams of speculative thinkers, the precepts and priestcraft, and the maximum of the market and the caucus.

The problems of education are mainly problems of evolution, problems concerning growth and development. The new education will be conceived and ordered as a biological science,—as the quintessential of the biological sciences. Then will the teacher strive to play the part of an intelligent, loyal, efficient coworker with nature in so shaping and ordering nurture that the child shall develop naturally and fully

into a healthy, vigorous, intelligent, active, God-fearing citizen of the world.

Lord Bacon closes the announcement of his "Instauratio Magna" with the following invocation:—"When Thou hadst surveyed the works which Thy hands had wrought, all seemed good in Thy sight, and Thou restedst. But when man turned to the works of his hands, he found all vanity and vexation of spirit, and experienced no rest. If, however, we labor in Thy works, Thou wilt make us to partake of Thy vision and Sabbath; we therefore humbly beseech Thee to strengthen our purpose, that Thou mayest be willing to endow Thy family of mankind with new gifts through our hands and the hands of those in whom Thou shalt implant the same spirit."

What higher privilege or reward can the student or teacher seek than to be enabled "to endow the family of mankind with new gifts?"

WHAT INFERENCES MAY BE DRAWN FROM CASES OF PULMONARY TUBERCULOSIS REPORTED TO HAVE ORIGINATED IN COLORADO.¹

BY S. G. BONNEY, A.M., M.D., DENVER, COL.

In the consideration of this question it is desired to propound a reasonable inquiry as to the practical relation of the existing conditions in Colorado to the development therein of pulmonary tuberculosis.

During the past few years the attention of the profession, and the laity as well, has been drawn to the increasing number of reported cases of this disease developing within the State.

Certain physicians of recognized scientific attainments have already considered the evidence sufficient in its authenticity and in its scope to justify the promulgation of immediate conclusions. The interpretation made has been positive and unequivocal to the effect—

(1) That the obvious source of infection has been largely referable to direct contagion, owing to the large assemblage of pulmonary individuals.

(2) That the attraction of our climatic conditions is becoming for our present resident population an embarrassing, if not undesirable, feature.

(3) That as a logical result of further importation, tuberculosis is likely to become an important indigenous disease in Colorado.

(4) That the very means, therefore, of past preservation to a large proportion of our inhabitants is becoming an increasing source of future danger; the inference being implied of the possible ruinous effect upon our communities in generations to come.

(5) That, apropos of the alleged alarming dissemination of tuberculosis in Colorado, there should be enacted and rigidly enforced more stringent regulations pertaining to the control or prevention of the disease.

(6) That, in addition to the prophylactic measures already employed by the conscientious physician, registration and the segregation of tuberculous patients, with perhaps other still more radical measures, be insisted upon.

The assumption through the foregoing conclusions

¹ Read before the Colorado State Medical Society at its Annual Meeting in Denver, June 15, 1897.

is evidently to the effect that with the enactment of measures looking to the progressive destruction of the tubercle bacillus the disease may eventually be eradicated from the world.

Before proceeding further, I wish to define my position with emphasis in hearty support and commendation of the admirable efforts of our State, county and municipal health authorities along the lines of preventive medicine. I desire to accord them a keen appreciation of the value to society of the noble work already accomplished. I have no sympathy for the ignorance of those who refuse to accept the logic of facts, or the indifference of those who do not co-operate in the energetic and capable enforcement of the health regulations.

I am impressed, however, that we have gone quite far enough in the way of legislative measures relative to tuberculosis, and seriously question, lest in the midst of the present agitation, professional enthusiasm coupled with an immoderate popular sentiment is leading us a step too far, although admittedly in the right direction.

I am convinced that as yet the data introduced upon this subject are entirely too meagre to warrant positive conclusions as to the supposed evidences of contagion in our community. On the contrary, I submit that the accumulated evidence of numerous observers in this country and abroad is such as to modify, if not controvert, some of the conclusions quoted as being untrue to the established facts of scientific investigation and clinical experience. I protest, therefore, against an undue agitation at this time on the ground of insufficient testimony, and because a popular verdict prematurely rendered is attended with unfortunate results of a practical nature to be mentioned subsequently.

In support of my position I will call attention to—

I. Sources of error in the compilation of official statistics.

II. Clinical testimony concerning the extent of non-imported cases.

III. Absence of proof that cases reported as developing in Colorado were actually contracted here.

IV. Recent scientific observations as to the practical contagiousness of tuberculosis.

I. A review of the material offered as evidence to establish the large proportion of cases developed in Colorado to those contracted elsewhere indicates that the chief source of information is found in the records of the Denver Health Department. The health commissioner, in his annual report for 1896, states that the number of deaths during the past year from tuberculosis developed in Colorado "is a little more than one-sixth of the total tubercular death-rate." He also notes that the percentage of deaths from tuberculosis contracted in this State has been progressively increasing during the past four years. In 1893 the proportion is stated to be 11.25 per cent.; in 1894, 13.7 per cent.; in 1895, 15 per cent.; in 1896, 18.4 per cent. The impressive deduction is then made that primary cases of tuberculosis are increasing at such a rate as to carry conviction concerning the communicability of the disease in the midst of our resident population.

In forced recognition of the unfortunate influence exerted, I cannot allow such statements to go unchallenged. Disavowing any desire to reflect unpleasantly upon our local health department, or to impair in the

slightest degree its influence for good, I am, nevertheless, compelled to refute both the premises offered and conclusions reached from the evidence presented.

I assume that an effort has been made to secure as perfect accuracy as possible in the preparation of the statistical tables and charts presented by the Health Department. It is to be regretted, however, that the portion of the annual report of our health commissioner bearing upon this highly important subject is found to be replete with errors of varying description and to such an extent as to practically nullify the usefulness of the work. Numerous mathematical discrepancies are to be found by a comparison of the various tables and statistical data, where uniformity of results should be expected. It is hardly profitable at this time to attempt to record all the individual inconsistencies. Accepting, however, for the sake of argument a portion of the report, and assuming that the number of cases reported to have originated in Colorado to be strictly authentic for scientific purposes, although I am informed the only source of information has been the returns upon the death-certificates, are the ultimate conclusions logical or tenable?

I must insist at once that the percentage of *deaths* is by no means a fair criterion of the proportion in Denver of cases said to have developed in Colorado to those contracted elsewhere. Those who have developed the disease in Colorado are, in the vast majority of instances, residents of the State who have either established homes of their own or are inmates of our charitable institutions, and, therefore, subsequently become recorded as dying in Colorado. On the other hand, it is well known that the pulmonary invalid from a distance, with hopeless prognosis, is usually, for humanitarian reasons, advised to return to his home. Comparatively few of such cases, fortunately, are permitted to die in Denver, removed from family and friends.

The proportion, then, of one to six does not for this reason alone properly apply, as might be inferred, to the existing cases of tuberculosis in Colorado, of whatever origin.

Furthermore it is easy to demonstrate the fallacy of the alleged rapid increase in the percentage of deaths from tuberculosis contracted here. The records of the Health Department show upon their face that in four years the percentage has progressively increased from 11.25 per cent. to 18.4 per cent. An analysis, however, of the data upon which these figures are based discloses mathematical inconsistencies and misinterpretations sufficient to qualify the results and to invalidate the conclusions therefrom.

It is, of course, apparent that a change may be effected in a given ratio by a change in *either* of its terms. In other words, the percentage of deaths from primary tuberculosis developed in Colorado may be increased from year to year by reason of an increase in the number of such deaths, the total tubercular death-rate remaining unchanged. Likewise the proportion is increased if the number developed in Colorado is constant, provided the entire death-rate from tuberculosis is diminished.

While the figures of the Health Department show the *percentage* to have very rapidly increased, the actual number of cases originating in Colorado is but slightly larger for the four years, while the total number is considerably less; thus, of course, affecting an increase in the proportion, but possessed of no further

significance. Thus in 1893 the total number of deaths from tuberculosis is reported as 435, of which 49 are specified as contracted in Colorado, establishing the percentage of 11.25. The next year the total number was 377, a diminution of 58, while the number contracted in Colorado was 51, an increase of but two cases for the entire year. It is obvious at once that the increase is entirely insignificant, yet the proportion is published as being 13.7, a gain of over 2.5 per cent. in the deaths originating in Colorado in one year. The number of deaths in 1896 is but two more than for 1895 and but 17 more than for 1893, in spite of an increase of 25,000 in our population. Yet the laity are being educated to believe that tuberculosis originating here is advancing with alarming rapidity, even to the point that one in every six consumptives residing in Denver has developed the disease in Colorado.

Again, it is interesting to note that there is a striking lack of uniformity in the methods employed for the computation of official percentages which are presented for scientific comparison between succeeding years. Thus in 1896 the percentage is obtained by dividing the number specified as having originated in Colorado by this number *plus* those not contracted in Colorado, ignoring those concerning which no specific mention is made upon the death certificates as to where contracted. In the three preceding years, however, this latter rather considerable class was included in the total number, and of course materially influenced the resulting percentage.

Without entering upon a discussion as to the individual merits of the two different methods of computation, I will simply contend that for the establishment of reliable comparisons the same mathematical process should be observed in each instance. Otherwise, "as well might we attempt to add pears to apples and express the sum in plums." If the method employed in 1896 giving a percentage of 18.4 is correct, and the same rules of computation be applied in 1893, the percentage for the latter is found to be 15 per cent. instead of 11.25 per cent., or an increase of but three per cent. for the four years, rather than an increase of seven per cent. as we would be led to believe.

I am convinced, however, for reasons previously stated, that reference to the proportion, no matter how obtained, of deaths from cases developed here to the total death-rate of tuberculosis in Colorado, is of but slight, if any, practical value in determining the actual relation.

While no method of forming an estimate upon this matter is without its objections and possibilities of error, I can suggest none more satisfactory than the proportion of such cases according to the population. I am well aware of the deficiencies of this method, particularly in a city of this character. The fact remains, however, that the floating element of our population is a constant factor from year to year, that the city is steadily increasing in size, and that the pulmonary invalids who have secured improvement are remaining to form a portion of our population.

Accepting the figures of the Health Department for 1895 and 1896 concerning the number of deaths from primary tuberculosis and the population of Denver, it is found that the percentage of deaths from tuberculosis developed in Colorado per one thousand inhabitants, is less in 1896 than in 1895, being .044 in 1895 and .043 in 1896, in face of the fact that the per-

centage per one thousand of the total deaths from tuberculosis chances to be precisely the same for the two years. The recent official estimate, however, based upon careful investigation shows a population in the beginning of 1897 of about 163,000. If this is correct, the proportion per one thousand for 1896 would be .040 as against .039+ in 1895. It does not appear therefore from a fair and reasonable interpretation of the corrected data registered at the Health Office that consumption developed in Colorado is actually increasing to any extent. If so, it remains to be demonstrated by logical process of reasoning and accurate statistical observation not as yet introduced.

It may be mentioned in this connection that it is somewhat remarkable that tuberculosis has not developed with greater frequency in Colorado and in Denver particularly. It is generally recognized that no race is immune and that no locality is entirely exempt from the disease which has prevailed the more extensively the world over as people have congregated to a greater degree. It is but natural then, for general reasons, that tuberculosis should originate in Colorado to some extent in spite of our climatic conditions.

An especially predisposing factor of considerable importance is the changing character of our infant and youthful population. Physicians with some experience in obstetrical and pediatric work are beginning to note the relatively increasing number of children born in Colorado of tuberculous parents, and added to this the greater frequency of meningeal manifestation, and general tubercular infection in the very young. This is, I believe, a legitimate result of the predisposing influence of inheritance, namely, the increased vulnerability of the tissues and the weakened individual resistance, rather than an expression of the increasing dangers of infection.

While the presence of the bacilli is an essential factor in the development of the disease, likewise is the character of the soil, else "the seed has fallen in stony places." The wide distribution of the bacillus and the innumerable opportunities for exposure in everyday life, without subsequent evidence of infection, emphasizes to my mind the paramount practical significance of the predisposing influences. The strong inherited susceptibility of a considerable portion of our younger population is an important component factor in the problem under consideration in Denver, not applicable in like degree to any other locality. It is manifestly unfair, in view of the special predisposition, to represent without qualifying explanations such infant cases as instances pure and simple of infection contracted in Colorado, yet an investigation of the records of the Health Department shows that of 66 cases reported for 1896, about one-fourth are in children classed as being under from seven to fifteen years of age and over one-sixth under four or five. Also that of a total of 230 cases in the past four years, nearly one-third of all varieties of tuberculosis are under seven to fifteen years, and in round numbers one-fourth under four or five years.

Of greater importance still is the fact that a very considerable portion of these are found to be cases of tubercular meningitis, the development of which results as little perhaps from direct external contagion as that of any variety of tuberculosis. All authorities are unanimous, that in nearly all instances this manifestation of a general infection is a secondary process, "An auto-infection resulting from a pre-existing tuber-

cular focus, which may be latent or unsuspected." In children the primary source of contagion is found to be chiefly tubercular bronchial glands. I submit that such cases do not belong in the category of "consumption contracted in Colorado," although strictly speaking it would appear at first thought that observations with reference to children born here should be particularly conclusive.

II. Clinical testimony concerning the extent of non-imported cases.

It seems highly proper to consider the evidence adduced from the experience and reported observations of medical men in Colorado. I have not considered it necessary to institute a personal inquiry among the physicians of the State. As this work has been previously done and considerable interest awakened in the subject, it may be fairly assumed that the results of investigations have now been mostly reported and that sufficient material has been contributed to warrant at least a provisional estimate of the frequency of the disease in the experience of our practising physicians.

I will refer briefly to the data introduced, as far as I have been able to learn. In 1886 Dr. Lee, of Fort Collins, in answer to 110 personal letters to the physicians of Colorado received a total report of 14 cases that had been observed during a period of two years. In 1891 Mays² reported the substance of a communication from Dr. Adams, of Colorado Springs, who stated that after a painstaking investigation he could only discover seven cases of consumption which had originated there during an entire period of seventeen years; not one of these cases could be attributed to direct contagion. At about the same time Dr. Solly is quoted in "Hare's Therapeutics," as follows: "Living as I have done for the past sixteen years among a people of whom perhaps 30 per cent. come to the country with tuberculosis, and not a few of whom live under hygienic conditions in crowded lodgings and where free expectoration is carelessly practised, I know of only four cases of phthisis which could be fairly assumed to have originated in Colorado." In 1892 Dr. Gardiner,³ of Colorado Springs, reported a total of 10 cases observed by the different physicians of that city during the previous fifteen years. This comparatively insignificant number is in face of the fact that the character of the population and the immediate conditions were such as to favor the development of tuberculosis. He states, "that the well ones are frequently closely confined with the sick, with the attendant anxiety, work and worry, and there are many houses in which numbers of people have died from the disease." He adds, "With one exception not one of the 10 cases was exposed to phthisical contagion, nor as far as can be ascertained lived near one with phthisis or had lived with or nursed any one with phthisis for a long time before developing the disease; not one had an occupation that brought him in contact with the sick."

Dr. Solly has been recently quoted by Dr. E. O. Otis,⁴ of Boston, as follows: "The dangers of contagion from the consumptive are so easily controlled that it is by no means necessary to separate consumptive from healthy persons. At least one-third of our population are consumptives; the town which contains some 15,000 people has been established

twenty years. An inquiry made by interested physicians into the number of cases known to have originated in the town resulted in a report of 20 in all. Although it is probable that our brilliant sunshine and dry air more quickly destroys the vitality of the bacilli than an Eastern atmosphere, yet in the poorer lodgings of the town there are many illy-ventilated rooms, inside or on the north side of the buildings inhabited by consumptives and their families, where recklessness of expectoration and carelessness of ordinary cleanliness are marked features of their domestic menage. Yet cases of contagion do not average more than one a year."

Dr. P. V. Carlin of this city, whose opportunities for clinical observation upon this subject are perhaps not surpassed by any physician in Colorado, informs me that during the past fifteen years in active practice in Denver he has not witnessed over an average of one case a year that could be properly classed as originating in Colorado.

In marked contrast to the evidence thus far presented is the experience of Dr. Henry Sewall. Two years ago he submitted a series of 21 cases observed by himself in four years;⁵ 14, however, were hospital patients belonging to a class who from their environments and surroundings, hygienic and financial conditions are more especially predisposed and possibly subjected the more to direct contagion, and should not, therefore, be considered as average patients. No mention is made of nationality, which is somewhat important as regards racial predisposition and prognosis; neither does he state the existence or absence of family taint, admittedly of some significance relative to the individual susceptibility. His cases, however, are very carefully and ably analyzed. Fifteen of his 21 cases were of pulmonary tuberculosis; of the remainder one was simple tubercular meningitis, one with pulmonary and meningeal tuberculosis. Another he stated to have probably been infected from infancy. Two were miners living at high altitude. It is pertinent to state, as suggested by Dr. Jayne, that such cases should not be included in a list of cases developing in Colorado, although the bacilli may chance to be present in the sputum. The condition is usually one of chronic bronchitis with emphysema, associated with cardiac disturbance. Such influences and the character of the occupation certainly render the soil favorable for infection, but the evidence is more than presumptive to the effect that the presence of bacilli is not the essential factor in the pathology of such cases. Five other cases were ranchmen and laborers with the possibility of contagion presumably very slight. In but six of the 21 cases could a definite possible source of contagion be ascertained. While Dr. Sewall's paper is of decided value in throwing another light upon the aspect of the question, I am not as yet prepared to accept in full measure the conclusions drawn from his single experience. I cannot subscribe to the spirit which is suggested by his words, "that consumption contracted here is making its way to the front as a scourge to us"; an appeal "that we take up arms against this common enemy." In a later communication⁶ reference is made to those of the medical profession, "who look upon the facts presented with a coolness amounting to indifference." While I have the most profound respect for the

opinions of the writer, I must confess that in this instance I am not as yet convinced and am still waiting for the facts.

Dr. J. N. Hall has recently reported 13 cases from his own experience in Colorado. He states, "that seven of the cases were seen at an altitude of 4,000 feet in Logan County, a sparsely settled farming and grazing region, where theoretically the influences favoring the origin of the disease should be at a minimum." But he adds, "In almost every case there were, either because of heredity or because of the presence of some well-known predisposing cause or of special exposure, sufficient ground for the development of the trouble." Of the six cases reported from Denver, five presented well-marked family predisposition.

The report of Dr. Hall is very much in accord with my own experience. I have collected a record of 16 cases observed in private practice during a period of five years in Denver. A direct family predisposition could be traced in nearly one-half the cases. Three were miners and strictly speaking should be excluded for reasons previously stated. With four, the occupations and habits of life were such as to markedly favor contagion, although no source could be definitely ascribed. In two of these the nationality also predisposed to some extent. One developed the disease shortly after pneumonia with empyema. The presumption is here strong that the tubercular infection had long preceded the pneumonia and had remained latent, rather than to have originated subsequently. I may add in this connection that in several of my cases, on account of the comparatively short period of residence in Colorado, I am unable to assert that the disease actually developed here.

III. Absence of proof that cases reported to have developed in Colorado were actually contracted here.

It is somewhat noteworthy that the source, namely, the Denver Health Department, from which emanates chiefly the statistical information, with its direct and implied inferences, contains no data whatever as to the period of residence in Colorado at the time of the recognized development of the disease. This, I contend to be a consideration of the utmost importance which cannot be ignored in the compilation of official statistics, without seriously impairing the value for scientific purposes. The fact that an individual is taken ill with tuberculosis even one or two years after arrival is no evidence that the disease was originally contracted in Colorado. As a matter of fact, I have in numerous instances discovered signs of unsuspected infection in some member of a family other than the patient for whose sake the change of climate was made. I have no doubt that many similar cases might subsequently be reported as having developed here. It is not, however, to such palpable cases alone that I especially refer, but rather to the considerable class with latent infection.

The tubercle bacillus is known to be ubiquitous to such a degree that complete escape from its presence in well-populated communities is practically impossible; exposure is almost constant, infection frequent. The degree and results of the infection are dependent upon the character of the soil. If not upon good ground, even a considerable infection may present no immediate evidence of its presence. It may result unknown in ultimate arrestment, or years later under changed conditions may become an active process according as the individual resistance is lessened. Moreover,

a single exposure is not sufficient to induce the disease. The contagion is slow and incremental in character. The extremely slow growth of the tubercle bacilli has been generally recognized.

About one out of every seven individuals is estimated to die of tuberculosis. A large class are known to have been infected, but die of other diseases with the tubercular involvement unrecognized. Attempts have been made from post-mortem observations to approximate the relative number of such cases.

Osler refers to the experience of Coats in London as reported by Fowler in 1892. He concludes, "that about 23 of the persons who die of disease unconnected with tuberculosis have been at a former period of life affected with some form of internal tuberculosis." Allusion is further made to the investigations of Brouardel,⁷ "who found evidence of cured tubercle in the apex of the lung in 60 per cent. of those over thirty years of age whom he examined after death from violence." The statements of Osler upon this subject are impressive. He says:⁸ "The frequency with which foci are met with in the lungs and in the bronchial glands is extraordinary, and the statistics of the Paris morgue show that a considerable portion of all persons dying suddenly or by suicide, present evidence of disease in these parts. Biggs reports that more than 60 per cent. of his post-mortems show lesions of pulmonary tuberculosis. In 125 post-mortems at the Foundling Hospital in New York the bronchial glands were tubercular in every case. In adults the bronchial glands may be affected while the individual is in good health. H. P. Loomis found in eight of 30 cases in which there were no signs of old or recent tubercular lesions, that the bronchial glands were infective to rabbits." The experience of Loomis is also referred to by Ingalls,⁹ as showing that "40 per cent. of the bodies of persons dying suddenly in general good health, apparently perfectly free from tuberculosis, have the bacilli in the bronchial glands." Osler's¹⁰ own experience has been less striking. He reports that out of 1,000 autopsies between one-quarter and one-fifth were found to have died of tuberculosis, and of the remainder $7\frac{1}{2}$ per cent. showed evidence of previous tubercular infection in the lungs alone, excluding, however, cases with simple fibroid induration.

He states, moreover, "that various observations have been made of late in which the percentage ranges from 27 (Bollinger) to 39 (Massini). In 200 autopsies in which this point was specially examined, Harris found 38.8 per cent. in which there were relics of former active tuberculosis. The statement is made by Bonchard that in post-mortems at the Paris morgue, generally upon persons dying suddenly, the percentage found with some evidence of tubercular lesions, active or obsolete, is as high as seventy-five.

Additional testimony could be cited if necessary, to demonstrate the extraordinary frequency of unsuspected tubercular infection. Corroborative evidence is found in the not uncommon rapid development of the disease, previously latent, following measles and whooping-cough and in the occasional initial hemorrhages of tubercular origin preceding the existence of either signs or symptoms. It is justly assumed that one in every three or four persons is tuberculous

in some way. The average duration of life for a consumptive after the recognized development of the disease is variously estimated at from three to seven and one half years according to the peculiar class of patients in the experience of the observer.

In view of these facts, is it not somewhat extravagant to record all cases as instances of primary infection in Colorado without recourse to a diligent and painstaking investigation concerning their history and period of residence in the State before the development of the tubercular manifestations? Is it not highly probable that a considerable proportion of such cases are but instances of a latent infection brought into subsequent activity?

If lessened individual resistance is the essential factor in transforming a previously latent infection into an active process, why should not this diminution of the resisting power occur in Colorado as in any other place; and if so, why should not we meet with cases developed here but originally contracted elsewhere? What evidence can be adduced to show that these cases actually originated in Colorado and are not a part of the large class with existing but previously unrecognized infection? Also, as has been wisely suggested by Dr. Crouch, why should not the longer time of residence in Colorado show a corresponding increase in the number of such cases on account of the greater likelihood of periods of lessened resistance in the extended lapse of time? Dr. Crouch further defines his position, which is in accord with my own, to the effect that while direct contagion is an accepted possibility under certain conditions in Colorado as elsewhere, sufficient evidence has not as yet been adduced to demonstrate its results to the extent that is claimed, or to show that the infection in many cases reported was actually acquired in Colorado. On account of the several considerations previously presented, I do not feel that dogmatic inferences relative to contagion in Colorado are in any way justified at the present time.

IV. Recent scientific observations as to the practical contagiousness of tuberculosis.

While the communicability of the disease has been abundantly demonstrated and the means of contagion directly referred to the improper disposal of the sputum, together with a certain degree of susceptibility in the individual thus constantly exposed, it has also been clearly proven that with reasonable precautions concerning the sputum, the danger of the infection is practically nil; this is even true of an indoor life. It is safe to add, that without regard to special methods for the destruction of the sputum, the danger of infection in the open air is exceedingly slight. This would be particularly true in Colorado, with our large, open spaces and constantly changing air. The same may be applied with emphasis to Denver as a whole, although admittedly with less force in certain limited sections of the city. With our broad, clean streets, our expansive area, our brilliant sunshine and our varying atmosphere, it is difficult to conceive the necessary degree of concentration of the bacilli in any given area to render exposure in the open air a substantial possibility. A further important consideration is the influence of the sunlight in destroying the virulence of the bacilli. That the bacilli become inert after exposure to the sun's rays is generally agreed upon by those who have thus far conducted investigations, but the more exact period necessary to accomplish this has not as yet been accurately determined.

Dr. I. H. Hance states that as a result of his researches he is convinced that it is something over two hours, but can go no further than that at present. He says in his paper "Upon the Infectiousness of Dust in the Adirondack Cottages,"¹¹ "That the most powerful and at the same time freely obtainable agents are the sun's rays and diffused daylight; they can be used by everybody and have proven to be the most efficient disinfectants known." The observations of Ransome and Delepine, recently referred to by Dr. Bowditch and Dr. Otis, are to the same effect, namely, that exposure of dried sputum to sunshine for a few hours is sufficient to destroy all power for evil.

From the various experiments conducted, it appears that the danger of infection is dependent solely upon the drying and powdering of the sputum and the dissemination of the bacilli in the air before sufficient exposure to sunlight has taken place to render them inert. It would thus seem that the essence of the matter is largely contained in the relation of the direct intensity of the sun's rays at a given locality to the meteorological conditions favoring a rapid drying of the sputum and its subsequent dissemination as virulent dust.

It is evident that while the influence of our surpassing sunlight is certainly a factor of considerable value in the natural disinfection of the sputum, at the same time the attending dryness of the air with its constant motion would be expected to hasten the drying process and permit the wider dissemination of the bacilli, possibly before their virulence had been destroyed.

The only experiments that have been conducted in Colorado, as far as I am aware, having a possible bearing upon the subject, are those of Dr. Gardiner,¹² who inoculated guinea-pigs with sputum that had been exposed to the sunlight at an altitude of 6,000 feet during a period of one and three-fourth hours to twelve hours. The results of the inoculation differed in no material respect from the investigations conducted at sea-level. An exceedingly important observation is reported, however, by him, to the effect that a firm crust speedily made its appearance upon a mass of sputum thus exposed, which was usually broken only after considerable pressure. The important thought to me from this is, that while our atmospheric conditions conduce to the more rapid drying of the sputum, the powdering process is somewhat inhibited, and without the latter the bacilli are less capable of distribution as dust with virulent properties. In addition to this the constant, varying air movement, although setting the bacilli in motion to some extent, must be regarded for obvious reasons as a favorable influence.

As regards indoor life, the investigations of Flick have shown the danger of indoor infection under certain conditions. The oft-quoted researches of Cornet and others have demonstrated the infectiousness of dust from hospital wards, public places and rooms occupied by consumptives. Positive results from inoculation were obtained in one-fifth of Flick's experiments, but in no case where proper attention had been given to the reception of the sputum. The investigations of Hance along similar lines resulted in negative results in dust from sixteen out of seventeen Adirondack cottages, the exception being due to clearly as-

¹¹ Medical Record, December 28, 1895.

¹² Dangers of Tubercular Infection and their Partial Arrests by Climatic Influences, read before American Climatological Association, May 5, 1897.

signable causes. Gardiner inoculated the dust taken from different rooms in the largest hotel at Colorado Springs, occupied by consumptives for considerable periods, and obtained negative results in all of his eight cases.

Further observations of like character could be introduced were it necessary to establish the absence of infectious material in the air or dust wherever proper care is taken of the sputum. It is well to remember also that the development of tuberculosis following direct inoculation into the circulation from selected samples of dust from a given area in an animal especially susceptible is no conclusive evidence of the practical danger of contagion through the respiratory system of an individual. Added emphasis is given by the fact that bacilli have been repeatedly found in the nostrils of nurses and medical attendants, and have been capable of producing tuberculosis by inoculation in lower animals.

Clinical testimony as to the contagion in health resorts and institutions is of perhaps still greater interest. Cornet has reported the great mortality-rate from tuberculosis among inmates of convents and prisons. It must be recognized, however, that the manner of life in the religious institutions of Europe has been such as to specially predispose in the process of years to the development of the disease. With reference to prisons, Baer has shown that the highest mortality is exhibited not in those institutions where the ill are allowed to mingle with the well, but where the cell system is in force with the attendant depressing influence of confinement, but with no especial opportunity for direct contagion. This in spite of the fact as reported by Ziemssen that, "The volume of air is much larger than in the collective system; that the atmosphere is better and the floor and walls much cleaner."

The statistics from the Brompton Hospital in London have been quoted many times and variously interpreted. Williams reports the number of cases developed by the attendants, who come in very close contact with those affected, to be extremely insignificant. Bowditch¹² in commenting upon the increased death-rate from consumption among the natives of Nice and Mentone as reported by Knopf, aptly questions "Whether this increase of consumption is due to the lack of strict hygienic rules among the hotels and boarding-houses, or because the native population have changed their former outdoor occupation to the more confining life of hotel attendants." No attendant has ever developed tuberculosis at Dr. Trudeau's sanitarium in the Adirondacks. In the well-known sanitariums of Göbersdorf and Falkenstein during a period of many years, the number of cases originating in the institutions or in the neighboring communities have been very small indeed, owing to the strict precautions insisted upon with reference to the sputum. To present other equally familiar observations would be scarcely profitable.

I have endeavored to show that the full extent of the present crusade in Colorado is not entirely justified by the established facts of clinical experience nor by the generally accepted results of scientific investigation. Such being the case, it is certainly not in accord with those broad humanitarian principles which should have predominant influence in the solution of problems involving so much to a considerable portion of our fellow beings. As practical and natural results of the

existing agitation, I am compelled from my personal observations in Denver to recognize —

First, a growing feeling of apprehension in the midst of our community with reference to this somewhat mysterious, but ever-present danger of contagion.

Second, embarrassing difficulties in the way of securing proper accommodations for the consumptive.

Third, unnecessary humiliation, and lack of moral support with encouragement, to those entitled to every sympathetic consideration.

Fourth, a beginning disinclination elsewhere, upon the part of the profession and the laity alike, to have recourse to the Colorado climate on account of the reported conditions of contagion.

Were it necessary I could cite numerous instances from my own experience in corroboration of each one of the preceding statements.

Have the actual exigencies of the situation been sufficient to justify in the interests of the Society the development of an immoderate professional attitude and a somewhat intolerant popular sentiment?

Should these existing elements born of undue enthusiasm, although originally conceived in truth and science, be permitted to attain sufficient growth to overcome the beneficent possibilities from a judicious restraining nurture?

Is not an appeal to the intelligence with a view to securing earnest co-operation likely to be productive of better general results than an arbitrary enforcement of radical measures? The expediency of the latter, to the extent recently suggested, is not as yet recognized by the medical profession, and if carried out would not be correctly appreciated by the laity. Is it necessary in order to sufficiently educate, to create undue alarm? To what extent should the liberty of the consumptive, his relations to his family and to the community be disturbed?

These are questions to be answered in the calm judgment of the future, but concerning which a decision should not be hastily rendered.

Recognition is made of the benefits to society accruing from the present measures of prophylaxis and of the necessity perhaps for further instruction, but a protest is entered against an unwarranted legislative interference.

This paper is presented as a plea for conservatism in our thought and action at the present time.

Clinical Department.

PISTOL-SHOT WOUNDS OF THE ABDOMEN.

BY H. H. A. BEACH, M.D., BOSTON.

CASE 1. Half an hour before entering the Massachusetts General Hospital the patient, a man of twenty-seven years, was shot from a point only a few feet away. The ball, of 38-calibre, entered by a slit-like wound $1\frac{1}{2}$ inches below and on a vertical line with the right anterior superior spinous process of the ilium, and made its exit above the external abdominal ring of the same side, leaving a ragged discolored perforation in a thin subject — traversing the abdominal wall in a nearly horizontal line for about five inches, without perforating the peritoneal cavity or producing a fracture of the pelvis. The wound was sterilized. Some abdominal tenderness followed, and there was a line of

¹² Boston Medical and Surgical Journal, June 25, 1896.

ecchymosis marking the track of the bullet. Discharged well in 18 days.

CASE II. A boy, fifteen years old, was shot one and one-half hours before entrance, from a point four feet distant; the weapon was a revolver of 22-calibre. Pulse 100, respiration 24, temperature 100.4°. A circular wound, $3\frac{1}{2}$ inches above the pubes and slightly to the left of the median line. Although the peritoneal cavity had been perforated, there was no gaseous or fecal extravasation nor hemorrhage. Laparotomy. Inspection of the intestine revealed two double perforations of the *ilium*, which were closed with fine silk sutures. At another point the peritoneal covering of the intestine had been lacerated by the forcible embedding of a small piece of cloth and metal. These were cautiously removed without disclosing an opening into the gut, and the wound was closed by Lembert stitches of fine silk. There had been no hemorrhage or extravasation of intestinal contents into the peritoneal cavity. The bullet was not found. Recovery uneventful. The bowels moved from the third day. There was no wound of exit, but the x-ray showed the location of the bullet deeply imbedded at the right of the sacrum, proving that it had crossed the pelvis.

CASE III. A boy, sixteen years old, entered the hospital on the following day, one hour after accidentally discharging a pistol of 32-calibre while withdrawing it with his right hand from an abdominal belt. Pulse 100, temperature 100°, respiration 16. A circular wound, with blackened edges that would admit the end of a lead-pencil, was found on the left side of the abdomen, two inches from and a little above the anterior superior spinous process of the *ilium*. The clothing over the wound was blackened and charred.

After sterilizing the wound, a probe was entered and passed obliquely downward for two inches to the *ilium*. This track was laid open, and found to reach the peritoneum without perforating it. The direction of the bullet continued through a perforation of the bone, and was lost in the muscular structures outside of the hip. A counter-opening was made and the wound dressed. Bowels moved after the third day. The bullet was subsequently discovered by the x-ray at the inner side of the great trochanter about an inch below the surface, whence it was removed, its course having described nearly a half-circle. Recovery and discharge from the hospital at the end of five weeks.

TWO CASES OF CHOLECYSTOTOMY.

BY EDWARD H. KIDDER, A.M., M.D., FALL RIVER, MASS.

CASE I. Mrs. D., age forty-seven, had been a patient of mine for over a year preceding her first attack of biliary colic, February 7, 1896. Her symptoms from the first had suggested cholelithiasis; but as jaundice had never appeared, no positive diagnosis had been made. This first attack of colic, however, left no doubt as to the nature of her malady. The pain was intense, and the fever and pulse charts showed a high degree of inflammation of the biliary passages — even to the extent of suppuration, it was feared at the time. For five days the temperature ranged from 100° to 104°, and the pulse from 100 to 130. After three weeks' prostration she was able to be about again, but an exquisitely tender spot in the right hypochondriac region continued to harass her from this time forth. No jaundice occurred at any time.

On May 24th she had another attack, similar in character, and confining her to her bed for a month. Through the summer she lived in constant dread of another prostration, and constantly embarrassed in her work by the sharp stabbing pain in the right side that ensued upon any active exertion. As there was no improvement in her condition, and as she was almost incapacitated from attending to her duties as housewife, she readily consented to undergoing the operation of cholecystotomy, preferring its risks to her constant suffering.

September 12th was finally agreed upon, and after two days' preparation of the patient the operation was begun upon an improvised table set up in the "front room" of the farmhouse where she lived. She was etherized; her shoulders were raised upon an inclined plane of about 35°, and attached by straps passing under the arms. A vertical incision, four inches long, was made in the right linea semilunaris, just under the ribs, through one and a half inches of subcutaneous fat. The enlarged left lobe of the liver and the interlobar notch were revealed. The hand was then introduced in search of the gall-bladder, and a hard mass, the size of an egg, was found eight inches below and to the right of the wound. Adhesions were many, but were gradually separated by the fingers, and the mass was drawn up to the incision. It proved to be the gall-bladder, with apparently but one large stone enclosed. After careful walling off with gauze about the gall-bladder, it was incised. The walls were vascular and one-eighth of an inch in thickness, but healthy appearing. The stone was revealed; it was the size of a pigeon's egg, symmetrically ovoid, with two facets (weight 260 grains). The gall-bladder was almost entirely filled by it. The ducts were then palpated, and other stones located in the cystic duct. These were firmly imbedded and enveloped, about the size of chestnuts. Gradually these were loosened by deep manipulation, "milking" them back into the gall-bladder, and with considerable difficulty, owing to the fat abdominal wall and large liver. The first stone was crushed, the second extracted entire (weight 26 grains). A sound was then passed without obstruction the full length of the cystic and common ducts. Hepatic duct seemed clear. Nothing further made out. The bile now began to well up freely into the gall-bladder, but was restrained by gauze packing until a continuous catgut suture was placed through the muscular coat of the viscus, finally closing in the whole gall-bladder incision. Then a close continuous suture of fine silk was taken through the peritoneal coat, folding in and burying the catgut suture. The gall-bladder gradually became distended with bile, and as no leakage was observed and the seam appeared to be tight and safe, the whole was dropped back into the abdomen. A wick of iodoform gauze and a rubber drainage-tube were then carried down to the proximity of the gall-bladder, and the abdominal wound was closed, leaving only the small opening at the lower angle for the exit of the tube and wick. Large absorbent dressing applied. Patient in good condition. Pulse 112 and irregular; dropped to 100 and regular in two hours after enema of hot coffee and brandy.

September 13th. Temperature 100.8°, pulse 96. Passed a good night; slept six hours. The dressing was soaked with bloody serum. No trace of bile. Fresh dressing and pad.

September 14th. Temperature 100.6°, pulse 96. Has been very comfortable. Dressing showed very slight discharge on innermost layer.

September 15th. Temperature 100.6°, pulse 100. Dressing showed very slight discharge. The drainage-tube and gauze wick were then removed, and no evidence of bile leakage discovered. The small opening was then closed and held by a collodion dressing. One grain of calomel and, later, an enema of magnes. sulph. solution were given, and resulted in a good movement of the bowels.

After this the recovery was uneventful. The abdominal wound healed by first intention, and the patient sat up in bed on the fourteenth day. Sat up in a chair three days after, and was up and about on her feet on the twenty-fifth day. There was some tenderness in the region of the gall-bladder, but this has gradually decreased. One uncomfortable sequel was a partial paralysis of the arm, — precisely similar to crutch-paralysis — as a result of the strap supporting her upon the inclined plane. With more care this might have been avoided, but the "reversed Trendelenburg" position — if I may be allowed the term — was of the greatest advantage during the operation.

The patient has been doing a considerable amount of hard work since the latter part of October, and seems to be in perfect health.

CASE II. Mrs. R., thirty-two years old, a seamstress, in good health before her marriage, except for obstinate constipation. Soon after the birth of her first child, five years ago, she began to have pain in the region of the gall-bladder at times, attacks resembling biliary colic. Since the birth of the second child, about three years ago, she has had attacks every two months on the average. Frequently there has been deep jaundice, associated with the pain and soreness, and nearly complete anorexia and general prostration.

In June, 1896, she was treated medically in a Boston hospital, but with little relief. During the summer she was better for a time, but in November became worse again; and when I first saw her, in January, 1897, she had been in misery for nearly two months, requiring constant opiates, confined to her bed, and unable to take scarcely any nourishment. I found her somewhat emaciated, not jaundiced, evidently suffering from some acute inflammation. Pain referred to region of gall-bladder and liver, and considerable tenderness in that region; but nothing suggesting a tumor to be made out.

The history left little doubt as to the diagnosis, even leaving out the overwhelming evidence, as she considered it, of discharges of green concretions per rectum after the ingestion of quarts of olive oil. After a week's observation in the hospital, during which the acute inflammatory symptoms subsided, the operation was undertaken January 22d.

The patient was etherized and placed on a Trendelenburg operating table, in the reversed position, and the body raised to an angle of 40°. A vertical incision was made, four inches long, in the right semilunar line. The liver was not appreciably enlarged, and the gall-bladder easily found — size of a large hen's egg, hard, evidently much thickened, and firmly bound down to the liver by strong bands. This explains why it was not recognized as gall-bladder at the examination, for through the abdominal wall it had all the effect of a part of the liver itself. The adhesions were so dense that the attempts to loosen or draw out

the viscus were given up. After walling off around with gauze, an incision one and a quarter inches long was made in the gall-bladder disclosing a thickness of the walls of one-third of an inch. The contents were then scooped out — consisting of gall-stones from the size of a marble to the head of a pin — 28 larger ones in number, mingled with mucous-purulent secretion. One stone was tightly held within the cystic duct, and was dislodged with great difficulty. A sharp spoon curette was finally employed, and the stone was fairly cut out of the enveloping pocket. It was then possible to draw it out of the duct. A probe was then easily passed along the duct, and the other gall-ducts were palpated as far as possible, without discovering anything more.

The incision in the gall-bladder was then closed with catgut sutures through the muscular coat; but the walls were so thick that it was found impossible to turn them in and bring the peritoneal surfaces together, as in my former case, therefore only a few silk sutures were introduced in addition to the others and in the same relations. Perfect and tight apposition seemed to be secured. An iodoform gauze wick was carried down to the gall-bladder through the abdominal wound, which was closed except for the lower inch.

There was a profuse discharge from the wound, during the first twenty-four hours; then very little; but as the temperature and pulse showed considerable inflammatory reaction, it was not deemed prudent to close the wound completely. Bowels moved by enema on the second day. The tract of the gauze drainage suppurated freely after a few days; and on the twelfth day a fragment of a calculus appeared with a little bright-yellow mucus. This happened again later, and the sinus slowly granulated and healed. The patient was out of bed on the thirty-fifth day. She has since been in excellent health such as she has not known since girlhood, and has no tenderness in the region of the wound. She uses Carlsbad salts freely now.

In this case the "ideal" immediate closure of the abdominal wound was not realized, yet events showed that no better procedure could have been followed than was carried out here. It would have been impossible, without adding much to the danger by an extensive separation of adhesions, to have drawn the gall-bladder up to the abdominal wound and have there fixed it for drainage. The plan of loosening the peritoneum from the abdominal wall and depressing it so as to attach its edges to those of the gall-bladder incision, and allowing free drainage thus, seems to have many disadvantages. Here was an opportunity to sew the thickened walls of the gall-bladder firmly together so that no fluid could escape seemingly, and then to provide for later suppuration if it should occur by the gauze drain. In view of the recent acute symptoms, suppuration should have been expected probably, although there seemed to be opportunity for drainage down through the gall-ducts.

COMMERCIAL WISDOM. — The following is from a daily paper: A "new" father in a Missouri town found a twenty-dollar gold piece tucked into the lining of a baby carriage he bought there, and in twenty-four hours there wasn't a baby carriage left on sale in the place. The dealers were the ones who laughed last.

New Instruments.

A NEW CUTTING-FORCEPS.

BY J. L. GOODALE, A.M., M.D.,

Assistant Physician for Diseases of the Throat in the Massachusetts General Hospital and in the Boston Children's Hospital.

THE instrument shown in the accompanying cut has been devised by the writer and employed with satisfaction for the excision of tissue in the nose, which cannot be advantageously removed by the snare or by the galvano-cautery.

It consists essentially of two slender parallel shafts, the lower five inches long, bearing anteriorly a Y-spring, each branch of which terminates anteriorly in a sharp-edged ring in a manner similar to that in Sexton's forceps, the upper shaft ending anteriorly in an eye in which the branches of the Y lie. Thus a forward movement of the upper shaft upon the lower brings the Y branches together and causes one of the cutting rings to pass within the other. The lower shaft posteriorly and inferiorly bears two large rings, one directly below the other, admitting the fore and middle fingers respectively, while the upper shaft is decurved for a vertical distance of an inch at its posterior extremity, which bears a revolving ring for the thumb. The shafts are held in apposition by two sheaths through which the upper travels upon the lower. In action, therefore, the fore and middle fingers are the fixed point, while closure of the cutting rings is effected by a forward movement of the thumb.

Two pairs of oval cutting rings are provided, which are interchangeable upon the lower shaft, one with its long diameter antero-posterior, thus permitting work in a narrow space, the other with the long diameter of its oval lying transverse and affording a broader cutting surface.

The instrument cuts readily both soft tissues and the bony structure of the middle turbinate.

In the removal of hypertrophied tissue along the lower turbinate, it is to be noted that the area of denudation should be narrow, not generally above one-fourth of an inch in width, although it may be over an inch in length and may penetrate deeply to the bone. The walls of the trench like deficiency thus formed come together during the process of healing and give finally a linear, often scarcely perceptible, cicatrix. (Removal of the mucous membrane over a wide area, on the other hand, may result in extensive scar-formation and scabbing.) The hemorrhage following the operation is sometimes considerable, unless a packing of the nostril is maintained for several hours.

In about twenty cases of hypertrophy of the lower turbinate the writer has employed this method of reduction of the hypertrophy on one side, using on the other side, for comparison, chromic acid or the galvano-

cantery. Examination after an interval of several months has shown in all cases, on the side of the excision, a more complete removal of the hypertrophy, without a greater amount of scar formation than on the cauterized side.

In three cases of ethmoiditis the instrument has readily removed the anterior end of the middle turbinate, and has been especially serviceable where a narrow configuration of the parts prevented the use of curved scissors, or of Hartmann's conchotome.

It has also been of great service in the removal of small portions of tissue for histological examination, in clearing away stumps of polypi, and in excising large pharyngeal follicles.

The instrument was made under the writer's direction by Messrs. Leach & Green of this city.

Reports of Societies.

NEW HAMPSHIRE MEDICAL SOCIETY.

ONE HUNDRED AND SIXTH ANNUAL MEETING, CONCORD, N. H., MAY 24, 25, 1897.

THE Society convened in Pilgrim Hall, and was called to order by the President, DR. A. P. RICHARDSON, of Walpole, at 11 A. M.

Prayer was offered by REV. ROLAND GRANT, D.D.

After the presentation of the reports of the several committees, the reading of papers was taken up, the first in order being an essay on

THE DEGENERATION OF EYES,

by DR. THOMAS HILAND, Concord, N. H.

He said that degeneration of eyes may be caused not only by excessive labor and confinement, and by intoxicants, but by astigmatism, also by weak extrinsic muscles. Very weak internal recti muscles are associated with weak ciliary muscles, which well fitted glasses correcting error of refraction will help but not wholly relieve.

In inflamed cataractous eyes the lenses generally become obscured much more rapidly than in the quiescent ones. This degeneration of lenses is far more common in elderly people than is generally supposed, for failure of sight is so gradual that great surprise is manifested when the patient is told that it is the eyes that are in fault and not the lenses. The milky, rapidly forming cataracts from diabetes mellitus belong to a distinct class, and have none of the appearances of senile degenerations; neither do traumatic cataracts.

The modern treatment for cataracts varies very little from that of seventy-five years ago. In uncomplicated cases extraction without iridectomy is more and more the fashion, certainly much easier for the operator; and results as good as the Graefe operation of ten years ago are obtained. The first symptoms of degeneration are loss of transparency, and the observer sees points at which light is absorbed or broken, that is, one finds dots and lines and smoke where nothing should be seen. Many a cataract operation is performed with the vitreous body so broken and muddy that good vision cannot be obtained, and in these cases some of the vitreous may be lost. This vitreous barometer foretells the well-being or the failure of the eyes. Degeneration of the vitreous can be stopped

when the cause is syphilis, slight hemorrhages, measles, or any other acute disease that does not prostrate too much, but not when the cause is debility of old age, optic nerve atrophy, ordinary hemorrhages, injuries from foreign bodies, suppurations in pyemia, detachments from malignant growths. If there be inflammatory action, try bromides and iodides internally, and if mostly in the ciliary region, atropia will be of great service put in the eye. Alkaline laxatives are indicated when constipation is present with portal congestion. Anemia, amenorrhea, great insufficiency of mitral or aortic valves may be the disease needing treatment, the faulty vitreous proclaiming disease somewhere which the surgeon should search out and have relieved if possible.

DR. H. DEW. CARVELLE, of Manchester, read a paper entitled

GLAUCOMA.

The symptoms of glaucoma may resemble rheumatism and neuralgia of the head and face, including the teeth and ear, sick headache, as well as some common forms of inflammation of the eyes, and it is sometimes attended with fever and vomiting. Atropine is especially harmful in glaucoma, and should never be used except with a full understanding of its action in the disease for which it is employed. The physician should make himself acquainted with the resistance of tension of healthy eyes when palpated, and remember that in glaucoma this tension is greater than normal. The disease is of more frequent occurrence in hypermetropic than in myopic eyes, the sclera in the latter condition being thin and yielding, and may be hereditary. Of the varieties of glaucoma, we have the primary and the secondary. In the acute form, the cornea is steamy and anesthetic, the pupil large, and does not react to light, the iris has lost its lustre and markings from edema, the aqueous humor is turbid, the anterior chamber shallow, there is circumcorneal venous injection, and fulness of the anterior scleral veins, and a dull purplish discoloration around the margin of the cornea. All these conditions are caused by an increase in the intraocular pressure.

In the simple or non-inflammatory form of glaucoma, the disease may come on very slowly in one eye, and there will be only slight, if any increased tension, excavation and atrophic changes of the optic nerve. In the acute, inflammatory form, the attack is often preceded by occasional obscurations of vision, rainbows around lights, and weakness of accommodation, requiring frequent changes of glasses. The inflammatory symptoms manifest themselves by intense hyperemia of the ciliary vessels, and the conjunctival vessels are congested to such an extent that the disease might be mistaken for a severe case of conjunctivitis or iritis. There may also be chemosis and even edema of the lids: there is marked photophobia and lachrymation. The eyeball during these attacks becomes almost stony-hard, and very sensitive to the touch. Iridectomy is the best method of treatment. The patient should be under general anesthetic, as the high tension of the eyeball prevents the action of cocaine. An incision is made with a cataract knife, in the sclera, close to the sclero-corneal junction, occupying its upper one fifth, and the corresponding segment of iris is to be excised close to its ciliary attachment. Great care should be exercised in making the scleral incision not to allow the aqueous humor to escape too

suddenly, thus lowering the tension too quickly and running the risk of intraocular hemorrhage, and in making the iridectomy, be careful to avoid leaving portions of the iris in the angles of the wound. The strictest antiseptic precautions are to be observed before, during, and after the operation. An operation to be successful must be done before there is much contraction of the field of vision, or degenerative change in the iris. The only successful treatment for blind glaucomatous eyes is enucleation.

DR. N. W. MCMURPHY, of Concord, read a paper on

TREATMENT OF UTERINE DISPLACEMENTS.

The most prominent surgical method looking to the permanent cure of uterine displacements is the Alexander. Ventral fixation has also been advocated and largely practised by many operators, but this is not to be compared with or substituted for the Alexander operation. The indications for this operation are as follows: (1) Uncomplicated retroversion or retroflexion, where the patient wishes to get rid of wearing a pessary, or where a prolapsed ovary or ovaries render the presence of a pessary so painful as not to be tolerated. (2) Retroversion or retroflexion, with prolapse, and if necessary, restoring the perineum at the same time. (3) Retroversion or retroflexion with slight adhesions, first breaking up the adhesions through an opening in the anterior or posterior fornix. Dr. McMurphy gave a very clear and complete description of the technique of the operation.

DR. HAVEN PALMER, of Plymouth, read a paper on

MUCOUS COLITIS.

The disease is generally found in women during the childbearing period, and frequently accompanying uterine disease. The symptoms which first attract attention are the mucons discharges and abdominal pains. There may be constipation or looseness of the bowels, the latter being the more frequent condition. There are present many of the ordinary symptoms of dyspepsia. The mucus appears in shreds and strips, and in the form of tubular casts of the intestine. The pain varies in character, from a dull ache to the most severe colic. In treatment, the first indication is for the relief of the abdominal symptoms. This is best accomplished in case of constipation by first giving a saline cathartic, or simply repeating a dose of calomel until the bowels act freely. Then irrigation once a day of the colon, the object being to unload the intestine of fecal matter and then wash away the mucus. Drugs should be avoided as much as possible, the essential points in the treatment being rest, irrigation of the intestine, and nutrition.

DR. M. S. WOODMAN, of West Lebanon, read a paper on

FOREIGN BODIES IN THE ALIMENTARY CANAL IN CHILDREN.

It frequently happens that smooth, insoluble bodies remain in the stomach or some part of the intestines a long time without either causing irritation or any considerable irritation. The first symptoms are usually general malaise with signs of indigestion, frequently vomiting, a quick, jerky pulse, great nervous disturbances, taking either the form of stupor or excitability, intense thirst, a foul breath, a tongue covered with a thick, brown coating which is apt to come off in patches,

and a peculiar aspect that can be learned only by experience. If the case is a severe one and the bowels move at all, patches of mucus and streaks of blood will soon appear in the stools. If the foreign substance is not removed and the other symptoms relieved, delirium, coma, or convulsions frequently ensue. The principal dangers in such a case are ulceration and perforation of the stomach or bowels, hemorrhage, gastritis, enteritis or peritonitis and meningitis. In most cases a simple laxative will dislodge the offending substance, but occasionally some object will become lodged at some point and resist all effort to expel it. In such a case if we can be sure of our diagnosis, the only way is to operate as early as possible. No remedy is so likely to give good results as the free use of castor oil.

DR. STILLINGS, of Concord, was glad to hear a good word spoken for castor oil, and said: This recalls an interesting case to my mind. I was called to a child about five years old, suffering from acute mania. The child was thrashing about the bed, and presented all the symptoms of violent mania. I concluded it must have some intestinal trouble, and gave it a very large dose of castor oil, instructing the mother to watch everything that came from the child. The first thing she got was two tablespoonfuls of black, hard tar that is used for roofing. I went back in about four hours, and she had four feet of woolen yarn. The child was a little quieter. I went back later in the evening, and she had a ball of yarn about the size of an English walnut. The child was perfectly well next morning, and I think it was the castor oil that did the business.

DR. G. H. GREELEY, of Thornton's Ferry, read a paper on

ACUTE CEREBRAL MENINGITIS.

The treatment of meningitis is embraced in the word "antiphlogistic." Bloodletting, cold applications, purgatives, counter-irritants, are then in order. Venesection ought always to be preferred to local bleeding, even in the youngest child. When venesection cannot be, for any reason, employed, blood should be freely drawn by means of leeches or cups. The head should be closely shaved, and the rubber coil or ice cup used constantly. The patient should be in a large, airy room, remote from all noise, completely darkened, and attended by a single nurse. Iodide of potassium, opium and ergot have operated more satisfactorily in my hands than anything else. Animal broths, the liquid peptonoids, and milk constitute the most satisfactory diet, and should be given to the limit of the patient's assimilating powers. Alcohol should be carefully avoided, except in the last stage of the disease. Early recognition and prompt treatment are of the greatest importance in all cases of meningitis.

DR. JAMES A. LEET, of Enfield, read a paper on

PHLEBOTOMY.

The doctor cited several cases of apoplexy in which he had used venesection, thereby greatly relieving the labored breathing and other distressing symptoms. In a very severe case of varicose veins and hemorrhoids a complete cure followed repeated phlebotomizing, which extended over a period of several months. The general health of the patient was also improved, insomnia and other nervous troubles gradually disappearing. In pneumonia he had never seen ill results from phlebotomy, but had known lives to be sacrificed in this disease by the use of opiates, which in his judg-

ment might have been saved by using a lancet and a mustard paste instead of opium. An unfortunate prejudice exists among the younger physicians of today in regard to phlebotomy. It was the abuse of a good and tried remedy a century ago that led to its practical disuse in modern times. We may well consider the reasonableness of this agent and its applicability in the various acute inflammations where it will relieve pain, reduce temperature, quiet delirium and shorten disease, provided always the physician uses judgment and does not attempt to treat all cases in the same manner.

DR. STACKPOLE, of Dover, believed phlebotomy beneficial in all diseases attended by congestion. In pneumonia he had used it with excellent results.

DR. C. S. ABBOTT, of Laconia, read a paper on

SOME OBSTINATE FORMS OF ECZEMA.

Eczema is really an inflammation of the skin, and is characterized by the same phenomena as inflammations elsewhere. There is no specific for eczema. The remedies which will give the best results are the saline cathartics, mineral waters, alkaline diuretics, calomel, etc. When there is some existing systemic disorder, the remedies of the greatest efficacy are iron, cod-liver oil, salicylates, colchicum, etc. Some cases will recover with local treatment alone. The most useful ointments are the zinc ointment, unguent diachylon, and those containing some form of mercury. Of all the remedies used for chronic eczema some form of tar is usually the best. This should not be used over a moist patch, but it is the remedy *par excellence* over a dry, scaling surface. The causes of eczema are as varied as its appearance, and are probably both constitutional and local. One of the most difficult forms to relieve is a chronic erythematous eczema of the face, because of its abundant nerve- and blood-supply, and of our inability to protect it from irritation. For remedies the more soothing applications, such as the zinc and lime-water wash, are indicated. Eczema is one of the most troublesome diseases of children, it being almost impossible to prevent the incessant rubbing and scratching. The method introduced by Dr. White, of Boston, is excellent. A skull-cap and mask, with holes for eyes, nose, mouth and ears, is made from old cotton cloth, and securely fastened behind. The child's hands must also be fastened to the sides, either by pinning the sleeves to the underclothing, or by passing an old pillowcase over the child's head. The inside of the mask must be smeared with a diluted zinc ointment. The course of the disease will often be much shortened by applying black wash as an evaporating lotion for fifteen minutes twice or three times a day. When the child is very irritable, bromide of soda may be necessary for a few days, until the itching, which always subsides with the disease, is of less intensity.

DR. A. S. WALLACE, of Nashua, read a paper entitled,

SUITS FOR MALPRACTICE.

It is said that there is no country in the world in which physicians and surgeons are embarrassed with suits for malpractice to such an extent as England and the United States. There are many cases of injured reputation, financial embarrassment, and even mental wreck resulting from such suits. Quacks or inferior, mischief-making physicians, jealous of those they cannot imitate, often condemn where they dare not per-

form. It is easy for them to suggest that the operation or fracture or whatever the case in hand might be, should have had a far more perfect result. A suit for malpractice is the only satisfactory remedy, which is aided and abetted by some unscrupulous lawyer. Our own State has just done the right thing in that line. Too much cannot be said in the way of thanks and appreciation of the step taken in this direction a year ago by this Society, of the hearty good-will and support of our governor, the work of the legislature, and the untiring efforts of our own local society in the passage of the New Hampshire Medical Law. One cause of suits, perhaps, is the fact that the physician frequently claims too much, declares that he can do things that he is by no means sure that he can do. For that reason we cannot be too cautious in expressing what we expect or hope for the case at the beginning. There are two ways of preventing these suits, first, no matter how simple the fracture is, we should not fail to have witnesses. Second, a perfect record of the case should be kept as to details of examination, conditions found, names of witnesses, etc., as they might prove invaluable in case of suit.

DR. I. L. CARPENTER, of Manchester, read a paper on

AUTOPSIES.

The first point emphasized in this paper was the fact that the ordinary physician should have a thorough understanding of the proper manner in which to perform a post-mortem examination. Great care should be exercised to note every detail concerning the body, its position, the condition of the limbs, the look upon the face; also note the appearance of the room, its furniture, marks of disorder, and whether any violence has been used.—a complete mental or diagraphical picture should be taken, better the latter if the physician happens to be an artist, for it is of great service in medico-legal cases. A record should be made, signed and sworn to by those present, who should be physicians, if possible. The external examination of the body should be very complete, nothing being omitted which might lead to identification or determination of the cause of death. A detailed account of the methods of examination of the internal organs was given.

SECOND DAY.

The usual reports were read, after which the election of officers took place.

The first paper read was an essay by DR. JOHN D. QUACKENBOS, of New London, entitled,

CAUSES AND RECENT TREATMENT OF NEURASTHENIA.

Although not an American affection in its origin, neurasthenia is peculiarly American in its distribution, owing to over-work, emotional excitement, and the continuous nerve strain incident to American fashionable life. There is a distinct line of demarcation between nervous exhaustion and insanity, in that the latter is amenable to corrective treatment. Neurasthenia is a depraved state of the nervous system, caused by the mal-nutrition of the nerve elements, through the abnormal disassimilation of the complex phosphorus-bearing nerve substances. The cause of neurasthenia is the intemperate exercise of the intellectual faculties, and the excessive indulgence of the emotions and passions. Emotional unrest is a far more prolific

cause of neurasthenia than is generally understood. Health and happiness depend upon well-nourished and under-worked cells. When over-worked the reparative processes are distanced by destructive metamorphosis; nutritive regeneration is unable fully to restore the wasted substance of the nerve-organs, which rapidly lose the power of regeneration and become incapacitated for the fulfilment of their functions. Hence the morbid impulse to ingest more food than can be oxidized; hence the phosphaturia and uric-acidemia, the indigestion and the neurasthenic liver. These are the effects of nerve starvation, not the origin of it. These results react as causes to perpetuate the nerve exhaustion. Treatment on the theory of cell-exhaustion and the practicability of cell feeding has been the most successful. If the rest be made long enough, the food stimulating enough, the sleep regular, the change of employment judicious, and all worry removed, most cases of neurasthenia may be really improved if not entirely cured.

In connection with feeding, the elimination of waste products and toxins is accelerated through the several channels of exit. The drinking of plenty of water, hot and cold, between meals is insisted on, to keep the kidneys flushed. Stimulate the skin with a daily bath and rub-down, and where the patient can endure the shock, the cold douche to the spine on rising. Keep the mind interested in something. Physicians are finding out that the occupation cure is preferable to the rest cure. Where insomnia persists, sleep must be induced by artificial means, but the best means to this end are exercise within the limits of fatigue, fresh air, and a nutritious and easily-digested diet.

DR. GEORGE W. GAY, of Boston, read a paper entitled,

WHEN TO CALL A SURGEON IN ACUTE ABDOMINAL AFFECTIONS.

This paper was followed by the Annual Address of the President, DR. ABEL P. RICHARDSON, of Walpole, his subject being

OLD AGE.

Several papers were read by title and referred to the Committee on Publication.

The following officers were elected for the ensuing year: President, DR. MOSES C. LATHROP, Dover; Vice-President, DR. GEO. H. SALTMARSH, Lakeport; Treasurer, DR. M. H. FELT, Hillsborough Bridge; Secretary, DR. G. P. CONN, Concord.

Following the introduction of the new officers the Society adjourned to the New Eagle Hotel for the Anniversary Dinner.

AMERICAN NEUROLOGICAL ASSOCIATION.

TWENTY-THIRD ANNUAL MEETING, WASHINGTON, D. C., MAY 4, 5 AND 6, 1897.

(Concluded from No. 13, p. 321.)

SECOND DAY. — WEDNESDAY.

ENCEPHALITIS WITH CHANGES IN THE PIA.

DR. ALFRED WIENER, of New York, read a paper on this subject and reported the case of a child three years of age, who, after meeting with an accident, suffered from an attack of acute (non-suppurative) meningo-encephalitis. The child recovered after six months of illness. It remained perfectly well, and after an

interval of three years, just subsequent to an attendance of three months at school, had a second attack, which proved fatal. The autopsy and microscopical examination showed an involvement of the pia as well as the brain and the characteristic picture of acute non-suppurative hemorrhagic encephalitis. He believed the first attack due to traumatic influences. The second attack was due either to influenza on account of the suspicious catarrhal symptoms present at the beginning of the attack, or as a result of mental strain in a child predisposed to such an attack. Special attention was called to the involvement of the pia, which represented a pathological condition often found in simple fibrinous pleurisy.

DR. COLLINS spoke of a young man with encephalitis. Speech was lost. Mental condition deteriorated and he ultimately became helpless. The left side of the body was spastic and parietic. There was no cranial nerve palsy. The autopsy revealed cerebral edema, some localized softening and acute non-purulent encephalitis.

DR. W. G. SPILLER, of Philadelphia, said that the spinal form is similar to acute polio-myelitis and acute poliomyelitis. He referred to a case with symptoms of typhoid fever, which subsequently developed eye-symptoms and proved to be encephalitis. In another case with choked discs, etc., and supposed to be due to tumor, encephalitis was found post-mortem.

DR. F. X. DERGUM, of Philadelphia, asked if evidence of general infection was discovered or if the kidneys were involved?

DR. WIENER replied that there was only acute congestion of the kidneys.

DR. PATRICK presented some specimens from a similar case in which there was external ophthalmoplegia.

DR. SACHS called attention to the practical difficulty of differentiating between encephalitis and meningitis. The greatest difficulty seemed to be in substantiating the early diagnosis of encephalitis. Not only the pathology should be made clearer, but also the diagnosis. In the majority of cases both forms may be combined.

DR. J. J. PUTNAM spoke of the importance of a toxic cause. In view of the favorable prognosis in the majority of cases, he thought that this element should be considered in the etiology.

DR. HERTER mentioned the case of a child with convulsive seizures, which seemed like infantile cerebral palsy, but microscopical examination showed encephalitis.

DR. ANGELL believed the differential diagnosis could be made if we bore in mind the symptoms of inflammation. Where the membranes are affected there is rigidity of the cervical muscles.

DR. WIENER in closing the discussion thought with Dr. Putnam, that the violence of the symptoms was very likely due to toxic conditions.

LITTLE'S DISEASE. SHALL WE RETAIN THE NAME?

This was the title of a paper read by DR. B. SACHS, of New York.

He said that the use of the term "Little's disease" has led to great confusion. German and French authors have criticized English and American writers for not recognizing the disease as a distinct clinical entity. The name has not been adopted by the latter for the simple reason that Little's disease cannot be

considered as anything more than a mere etiological group comprising those cases of early infantile spastic palsies which are due to difficulties during labor resulting in asphyxia neonatorum. It cannot even comprise all spastic palsies that are in evidence from the time of birth, for many of them are not due to asphyxia, but to developmental defects, more particularly of the cortical or cortico-spinal division of the pyramidal tract. Some authors would make a distinction between general rigidity and cerebral diplegias and would call the cases of the former Little's disease, but he is of the opinion that there is no rigidity without paralysis, and the difference is simply one of degree and not of kind. The division which the reader made into prenatal and birth palsies which has been endorsed by Freud should be continued and the name Little's disease should be dismissed since it represents no distinct clinical group, and since a number of different morbid conditions are responsible for the infantile spastic palsies, or the cases of general rigidity appearing at the time of birth or shortly thereafter.

DR. FREDERICK PETERSON, of New York, differed from Dr. Sachs, as he had found that the greater the extent of the paralysis the more the mental defect and epilepsy. At times he had found extensive paralysis without mental defect or epilepsy. He referred to 130 cases as having been reported in which there were 30 with hemorrhage into the spinal canal.

DR. J. W. PUTNAM, of Buffalo, said that cases varied in the symptoms according to their etiology. He spoke of two children in one family in whom there was extensive paralysis. One had marked mental defect and the other very little. Both pregnancies were attended with prolonged periods of vomiting.

DR. SACHS, in his closing remarks, said he had not entered into the pathology of the subject, but agreed with Dr. Peterson. There is often an association of cerebral and spinal lesions, but he was not ready to believe that the majority of these cases are due to spinal defect.

THE NATURE AND TREATMENT OF SPASMODIC TORTICOLLIS.

DR. G. L. WALTON, of Boston, read this paper.

He considered spasmodic torticollis as an affection of the cortical centres for rotation of the head. The pathology is not settled. The fact that it is sometimes easily inhibited does not establish a mental origin. Gross organic lesion is not present. Long continued habit may merge into spasm, as seen in certain occupations. Eye-strain sometimes plays a part through causing faulty position (oblique astigmatism, muscular insufficiencies). In one case it followed the wearing of a glass which increased instead of relieving an oblique astigmatism. The course of the disease is progressive. The principal muscles affected are the sterno-mastoid, splenius capitis, complexus, trachelo-mastoid, and the inferior oblique. The commonest form implicates the sterno-mastoid of one side and the posterior rotators of the other, less frequently the spasm is limited to the sterno-mastoid, occasionally to the posterior rotators of both sides (retrocollis) and rarely to the sterno-mastoid and posterior rotators of the same side. Treatment other than operative is ineffectual in well-established cases. Simple nerve stretching is unavailing. The only operations to be considered are resection of nerves and section of muscles. Operations are generally too limited rather

than too extensive. In most cases it will be necessary to resect the spinal accessory and the first three posterior branches of the cervical nerves. It will generally be wise to cut also the affected muscles. Muscle section alone has given good results (Kocher) but there is no reason to abandon nerve resection.

Absolute cure cannot be expected in over half the cases, improvement in a greater proportion, and failure in a certain proportion.

DR. DERGUM thought we should be conservative as to our view of the pathology. He did not regard it as limited to the cortex. In some cases the torticollis seems to simulate the occupation neuroses and is often cortico-spinal. He did not know of a case of absolute cure following operation. He referred to a case in which the spasm recurred after extensive operation. Some were benefited by rest and the use of gelsemium in increasing doses. His habit was to advise surgical operation at once in the majority of cases. He had never seen much benefit from resection of the spinal accessory nerve.

DR. C. L. DANA, of New York, said there were three different types or phases of the disease. One occurring in early life, associated with neurasthenic or hysterical manifestations. Another more serious type in middle life, which he looked upon as a degenerative neurosis. The third occurred in children at about the age of fifteen years, and was gradually progressive and incurable. The type must be considered in the treatment. He agreed with Dr. Walton as to the pathology. In a patient with the progressive type, the autopsy showed a degenerative process and chronic leptomeningitis of the convexity. He thought that many cases were primarily a cortical degeneration. The best treatment was prolonged rest and careful massage. Some cases are cured and others relieved. He did not believe drugs did permanent good. Surgical treatment was irrational in theory, and not of practical value in his experience, but he had never had the combined operation performed.

DR. C. K. MILLS had seen many cases. The only successful one recovered under the use of the actual cautery frequently applied and the administration of iodide and bromide of potassium. Gelsemium was the best drug. He had had various operations done but has never seen good results. Nerve stretching was of value. He laid great stress on absolute rest. He did not believe all were of cortical origin. At times may be of nuclear and degenerative origin and partly irritative.

DR. RICHARDSON, of Boston, discussed the subject from the surgical standpoint. He operated only under the advice of the neurologist. There had been a sufficient number of cures to justify the operation. He referred to a patient treated by a helmet with benefit, but such a method is generally intolerable. Surgical methods should only be undertaken after all other measures have failed.

DR. W. W. KEEN, of Philadelphia, also spoke from the surgical point of view. His experience was the same as that of others. In one patient, after the usual operation, he proposed operation on the cortex, which was refused. However, improvement subsequently occurred. Before surgical interference we must be certain that medical treatment, particularly absolute rest, has been properly and faithfully but ineffectually carried out. In his experience, operation had failed as to absolute cure. In a considerable pro-

portion relief was obtained. These operations are not dangerous to life. He was disappointed with resection of the spinal accessory nerve.

DR. V. P. GIBNEY, of New York, continued the discussion from the view-point of the orthopedic surgeon. His experience had been largely in torticollis in young children and adolescents from injury to the sterno mastoid. These are easily relieved. In the class of cases under discussion he knew of no form of apparatus that would take the place of operation. Apparatus might supplement operation. Had obtained no benefit from gelsemium.

DR. J. J. PUTNAM believed that the essential thing in the treatment was methodical education of the muscles. He knew of one patient who cured himself by voluntary efforts. These methods required many months.

DR. LANGDON mentioned the case of a young man who recovered. The treatment was absolute rest and stupefying doses of chloral and bromide for three weeks.

DR. W. M. LESZYNSKY, of New York, after briefly referring to his successful use of increasing doses of atropine injected into the spasmodic muscles, mentioned the case of a lady thirty-five years of age who had been under constant observation for the last eighteen months. The clonic spasm had previously existed for six months and involved the sterno-mastoid, trapezius and complexus. The sterno-mastoid was hypertrophied to about four times its natural size. Atropine treatment could not be carried out, owing to idiosyncrasy. Conium and gelsemium failed. After prolonged rest and tonic treatment, together with local massage, passive movements and educational gymnastics faithfully carried out, the clonic spasm was absolutely cured, having been absent for nearly ten months. This has however been replaced by a mild form of tonic spasm which is remittent. A peculiar feature in the case was the high specific gravity of the urine, which was due to urates. Whenever the gravity rose to 1.030 to 1.034 the spasm increased, seemingly indicating an autotoxic irritative element in the case. He believed that if these cases were treated early by the foregoing method very little would be left for the surgeon.

DR. PRINCE had tried atropine without benefit. The only case treated by massage and rest recovered. Some patients improve with apparatus. He thought this condition analogous to the occupation neuroses, and recommended education of the muscles.

DR. WHARTON SINKLER, of Philadelphia, considered this disease under three types: (1) Hysterical. (2) Disease or irritation of nerves. (3) Cortical. The hysterical closely simulated the organic form. In the second type he advised rest and massage, gelsemium or conium. If these measures fail he concluded they are cortical. Therefore operation on muscles or nerves is useless.

REPORT OF COMMITTEE ON AFTER-CARE OF THE INSANE.

This report was presented by Dr. H. R. STEDMAN, of Boston.

THIRD DAY. — THURSDAY.

SOME INTERESTING CASES OF BRAIN TUMOR.

This was the title of a paper read by DR. PHILIP ZENNER, of Cincinnati. Three cases were reported. (1) Male. Age thirty-four. Severe headache left

parietal region. Double optic neuritis. Only one convulsion. Complete relief of symptoms followed trephining of the left parietal region. Seven months later headache returned and left eye blind and muscles paralyzed. Eye was enucleated and orbital tumor removed. Relief of all symptoms for nine months. Growth is returning.

(2) Male, age thirty-three. Chief symptoms: Jacksonian attacks in left side of face, paresis of left arm and leg, left facial paralysis. Tenderness to percussion over left side of skull. Post-mortem, large tumor in left hemisphere pressing upon left central convolutions. The symptoms were on the left side of the body. Sections of the medulla revealed an absence of the crossing of the pyramids.

(3) Tumor in right arm centre. Chief symptoms were Jacksonian attacks and slowly progressing paralysis of the left arm and leg. Operation. Middle part of the central convolutions exposed, but the tumor could not be seen or felt. Autopsy revealed a deep-seated tumor (glioma) in the anterior central, encroaching slightly upon the first and second frontal and the posterior central convolutions. The incision in the brain had barely missed the tumor. There was at no time optic neuritis, and no manifestations of increased intracranial pressure. No vomiting, headache not intense and intellect clear. There was no impairment of sensation before the operation, but hemianesthesia immediately following it. It would seem that very slow destruction of the cortical motor area causes no sensory disturbance, while sudden lesions produce anesthesia. Such facts seem to indicate that the central convolutions have sensory functions, but are only a part of the sensory area. The Jacksonian attacks in this case were of a tonic character only. This was of importance in connection with the fact that the tumor was subcortical, such attacks occurring chiefly when the tumor does not involve the cortex.

SARCOMA OF MID BRAIN IN A CHILD, ASSOCIATED WITH ASYMMETRICAL HYDROCEPHALUS.

This was the report of a case by DR. C. A. HERTER, of New York.

The last two papers were discussed together.

DR. ANGELL had seen a similar case but the asymmetrical hydrocephalus was secondary to a cerebellar tumor. The child is still living and the disease is quiescent. Circumference of head was 22 inches.

DR. E. D. FISHER, of New York, cited cases in which the usual symptoms of brain tumor were absent. No paralysis, and no optic neuritis. He had frequently seen relief of symptoms from operation without removal of tumor. Localization of tumor by percussion of skull he thought was unreliable. In slowly growing tumors the displacement of fibre tracts is so slow that paralysis did not take place.

DR. PERSHING related the history of a middle-aged man. General convulsions, loss of consciousness, defective vision. Quadrantic hemianopsia. No headache. No optic neuritis. All symptoms increased. Paraphasia, word-deafness. Coma. Death. At the autopsy, tumor of left sphenoidal lobe, and infiltrating growth in pulvinar.

DR. LANGDON referred to a case with many symptoms of tumor. Nothing was found at operation. All symptoms improved. He had seen a tumor of pons and cyst of cerebellum with absence of decussation of motor tracts.

DR. FRY mentioned an instance of asymmetrical hydrocephalus where the diagnosis of cerebellar tumor was made. There was decided difference in the percussion note on the two sides. At the autopsy there was ventricular distention.

In tumor of cerebellum with ventricular distention, the peculiar cracked-pot resonance is probably due to vibration of bone separated at the sutures.

DR. PATRICK said that the majority of cases of brain tumor were of irregular type. General convulsions usually precede focal convulsions in deep-seated tumors. In operating it is proper to continue and go below, after the surface of the brain is reached. Careful examination of the visual field and speech defects are of much value in diagnosis.

The PRESIDENT reported four cases recently operated upon. Three came to autopsy. Percussion note was altered in three.

(1) Infiltrating sarcoma in temporal fossa. Progressive motor aphasia, right hemiplegia. Aphasia was the first symptom. Headache and optic neuritis. At operation nothing was found.

(2) Woman under observation two months. All general symptoms. Unilateral and general convulsions. Operation. Very large infiltrating gliosarcoma over entire motor area. Removal followed by extensive hemorrhage. Death on third day.

(3) Man. General symptoms and diagnosis of cerebellar tumor. At operation cerebellum well exposed and seemed perfectly normal. Opening enlarged upward to occipital lobe, and then lateral ventricle tapped and large amount of fluid withdrawn. All general symptoms relieved for two weeks. At autopsy, tumor found in cerebellum below surface of normal tissue.

(4) Child, with all symptoms of cerebellar tumor, blindness, etc. At operation occipital bone was found eroded and softened. Operation discontinued on account of extensive venous hemorrhage.

General symptoms are often due to effusion in the lateral ventricles. The percussion note is not a reliable sign, and affords no differentiation between cortical and subcortical tumors. He had seen two cases of operation on the post-central convolution, in which ataxia of the right hand developed but gradually disappeared. He had not seen ataxia as a permanent symptom of tumor, nor had he seen asymmetrical hydrocephalus.

DR. HERTER did not regard a marked degree of asymmetrical hydrocephalus as indicative of tumor in all cases.

EPILEPSY FOLLOWING INFANTILE CEREBRAL PALSY. IMPROVEMENT AFTER CRANIOTOMY AND EVACUATION OF SUBCORTICAL CYST.

DR. W. M. LESZYNSKY, of New York, read a paper on this subject and reported a case.

Boy, fourteen years of age. At second year left hemiplegia preceded by convulsions and unconsciousness. Epilepsy developed at twelfth year. At first attacks of conjugate deviation of eyes and head toward the paralyzed side, with transient loss of consciousness, increasing in frequency. Later, attacks accompanied by rigidity of left arm, then of arm and leg, and ultimately general convulsions and increasing mental enfeeblement. No clonic spasm at any time. After ineffectual medicinal treatment, exploratory operation. A large subcortical cyst was found under

the Rolandic area. The cortex was extremely atrophied. The cyst was evacuated. Absence of all epileptic attacks for three and one-half months. Then had seven general convulsions within eighteen hours. Cyst was again emptied, and attacks disappeared over three months. The cyst was again evacuated. Since then he has occasional mild attacks despite the use of bromide. He considered the advisability of permanent drainage.

DR. J. W. PUTNAM spoke of a boy in whom convulsions followed traumatism, sixty to eighty attacks daily. Fluid evacuated from cyst, and bandages were frequently soaked by the discharge for a week. Wound healed. No attack for several weeks. More fluid withdrawn, and continued drainage allowed. Convulsions ceased. Has had no attack in two years.

DR. ANGELL referred to a case of hemorrhagic meningeal cyst in a child having fifteen attacks daily. Cyst evacuated and no attack since operation three years ago.

DR. PERSHING spoke of a man with epileptic attacks following a blow on the head. A cyst was found over the face centre and drained. No attack in a year.

DR. WORCESTER had made seven autopsies in cases of infantile cerebral palsy. In six there was great asymmetry of the hemispheres. In one the lateral ventricle was greatly dilated.

The PRESIDENT had no experience with permanent drainage. Had always seen symptoms return after evacuation of cyst.

UNCOMMON NASAL PARESTHETIC NEUROSIS.

This was the title of a paper read by DR. SAMUEL AYRES, of Pittsburg, who reported the case of a lady twenty-three years of age, recently married and of a neurotic temperament. The nasal disturbance began eight years ago, and was characterized by periodic flushings over the end of the nose. The attacks have increased in frequency and now consist in a sense of burning in the integument of the end of the nose, or over the entire cartilaginous portion. At the same time, there is general restlessness and considerable mental depression. No cause could be discovered. Various remedies had been used, such as local applications and the internal administration of bromides, cannabis indica, ergotine, etc., with only temporary benefit.

STEPS TOWARD INSANITY.

A paper with this title was read by DR. SMITH BAKER, of Utica. He said that the biological doctrine that structure determines function is as applicable to the neuron as to other basal elements. Applied to insanity, psychiatry properly becomes an important branch of it. The primary presupposition of every instance of true insanity is, that it is based upon arrest of development and a nurture too faulty to correct this. The step which initiates the degenerative tendency is unphysiological marriage and the perverse tensions and reactions which grow out of this. Another step is where two healthy people vitiate themselves by over-stress or nutritional perversions during the child-bearing periods. With the individual, defective homing plays a most prominent part in fixating degenerative tendencies. Frequently the ordinary educational course, the universal leaning on proxies and various kinds of stimulants, are but ways of confirming all that is degenerative. Diseases and accidents are im-

portant because of the emotional stress involved. Arrest of development at puberty is serious always. The immediate causation of the structural change seems to come through exhaustion and auto-intoxication; this must interfere with the characteristic activity of the neurons, which activity seems to be on the point of discovery as an ameboid movement of the cell or its processes. Dissociation, confusion, systemization may thus come to be founded in actual structural defect itself, the result primarily of emotional stress in ancestry.

Papers read by Title.—"Microcephalus," by Dr. Frederick Peterson, of New York; "A Case of Syringomyelia," by Dr. Theodore Diller, of Pittsburg; "Studies in Scleroderma," by Dr. F. X. Dercum, of Philadelphia; "The Pathological Anatomy of Huntington's Chorea," by Dr. Joseph Collins and Dr. B. Onuf, of New York; "Two Cases of Basedow's Disease, with Autopsies," by Dr. C. L. Dana, of New York; "Two Cases of Acute Ascending Paralysis with Autopsies," by Dr. John Jenks Thomas, of Boston; "Report of Two Cases of Tumor of the Brain," by Dr. J. Arthur Booth, of New York; Exhibition of a Brain Receptacle, by Dr. Wm. C. Krauss, of Buffalo; "Report of a Case of Jacksonian Epilepsy," by Dr. Graeme M. Hammond, of New York; "Contribution to the Study of Vertigo," by Dr. Frank K. Hallock, of Cromwell; "Five Defective Brains," by Dr. Edw. Wyllys Taylor, of Boston.

New Members.—The following named gentlemen were elected to membership: Dr. Wm. G. Spiller, of Philadelphia; Dr. H. M. Thomas, of Baltimore, and Dr. Wm. Hirsch, of New York.

Honorary Member.—Dr. E. C. Seguin, of New York, was elected to honorary membership.

Election of Officers.—The following officers were elected for the ensuing year: President, Dr. Graeme M. Hammond, of New York; Vice-Presidents, Dr. Philip Zeuner, of Cincinnati, and Dr. J. J. Putnam, of Boston; Secretary and Treasurer, Dr. F. X. Dercum, of Philadelphia; Council, Dr. H. T. Patrick, of Chicago, and Dr. Chas. K. Mills, of Philadelphia.

Recent Literature.

Congenital Dislocation of the Femur. By DR. ED. DELANGLADE. Paris: Sternheil. 1896.

It is a pleasure to welcome as complete a monograph as this, treating of a subject which has interested Continental surgeons greatly in the last decade.

Delanglade, beside giving a careful account of the remarkable work of Hoffa and Lorenz, describes also the methods and cases of Broca, less known here, and gives an excellent *résumé* of those treated by himself as well.

When French medical writers are at their best, there is always the merit of clearness and of excellence of style, which, after German and some English medical literature, gives to the reader the pleasure of wheeling on a smooth roadway. Delanglade's monograph is a good illustration of excellent French medical literature.

Any surgeon who wishes to inform himself on this interesting subject will find this work of great value.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, OCTOBER 7, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE REDUCTION OF OLD DISLOCATIONS OF
THE SHOULDER.

J. FINCKH, of Tübingen, has published¹ an analysis of 100 cases of old dislocations of the shoulder treated at the clinic in that city. The periods during which the dislocations had remained unreduced varied from three weeks to seven years. In 73 of these 100 cases attempts at reduction were made which were successful in all but 25 cases.

A point of especial interest brought out by this paper is the influence of the length of time the dislocation has persisted upon the prognosis with respect to reduction. Only two dislocations under four weeks proved irreducible; and as these were complicated with fracture, they ought not to be included in the statistics. Of 20 dislocations from two to three weeks old, 19, or 95 per cent., were reduced. Of dislocations three to six weeks old, 24 were attempted, and 20 reduced, or 83 per cent. Between six and nine weeks, 11 dislocations were attempted, and seven, or 64 per cent., were reduced, giving an average in all under nine weeks of 84 per cent. The oldest dislocations which were reduced were twelve and a half and fourteen weeks respectively.

Finckh concludes from these cases that the prognosis of dislocations of less than four weeks' duration is good, as all, in the absence of complications, can be reduced. Up to nine weeks the prognosis is fairly good, as four-fifths are reducible. Beyond that period reduction, except by open incision, will be rarely effected.

A comparison of these conclusions with those reached by Lund² on the basis of an analysis of 27 cases from the Boston City Hospital, is of interest as showing a general coincidence in regard to prognosis.

Of the 27 cases published by Lund, 11 were under five weeks' duration, and all were reduced; 15 were under six weeks, and there was only one failure. There were no cases between six and nine weeks, and

only one at nine weeks, which failed of reduction; so that with regard to the prognosis between six and nine weeks there are not enough cases to be of value. Very probably the collection of a larger number of cases would raise the period in which successful reduction could be looked for to a time somewhat higher than six, though less than nine weeks. All the cases over nine weeks, however, failed of reduction except one, corresponding closely with Finckh's cases, in which only two over nine weeks were successful.

It would appear, therefore, to be apparently settled by the correspondence of these two analyses, that after nine weeks successful bloodless reduction will be the exception.

Of Finckh's hundred cases, only three were subjected to open incision. In one primary, and in two secondary resection of the head of the humerus was performed. The functional results after resection were fairly good.

HAS THE CELLULAR NUCLEUS INDEPENDENT EXISTENCE?

A VERY interesting paper was contributed to the Moscow Congress by Professor Loukianoff, director of the Institute of Experimental Medicine in St. Petersburg, on "Inanition of the Cellular Nucleus." Notwithstanding the great advances made recently in the science of cellular morphology, he called attention to the fact that there still remain important problems awaiting solution, such, for instance, as the conditions of life surrounding the cellular nucleus.

The nucleus is undoubtedly the most important element of the cell, but we know but very little as to its functions of nutrition and growth. To investigate certain vital functions of the nucleus, he had made experiments touching upon the changes produced in the nucleus when the organism is placed in a condition of inanition. The results of these experiments tend to prove beyond doubt that the nucleus is endowed with an independent existence.

Dr. London had investigated the influence of starvation of bacteria (an analogous problem). He found that bacteria subjected to starvation diminish rapidly to fifty per cent. of their former mass. After this period of diminution, a condition of equilibrium is established, when the bacteria show no changes. In this they differ from the multicellular organism. Along with these experiments, others were conducted on the cellular nucleus itself. Whilst investigating the changes produced in the pancreas of the guinea-pigs subjected to starvation, Brunner observed, that while the cell loses ten per cent. of its substance, the loss of the nucleus amounts only to three per cent. We are therefore justified in thinking, that the nucleus suffers less from lack of nutrition than the cellular substance, and although a part of the cell, it does not lose its autonomy. The cell again consists of various elements, the most important of which is the nucleolus.

Madame Dovranovitch, experimenting on changes produced in a starving organism, found, that while the

¹ Beiträge zur klinischen Chirurgie, Band xvii, Heft 3.

² Boston City Hospital Reports, Eighth Series, 1897, p. 370; Boston Medical and Surgical Journal, April 29, 1897.

cellular tissue lost forty per cent. of its mass, the nucleus lost twenty-five and four-tenths per cent., and the nucleolus forty-three and five-tenths per cent.

Dr. Laraveitch, experimenting in Loukianoff's laboratory on guinea-pigs, found, that while the body in general loses thirty-five per cent., the loss of the nucleus of the hepatic cell is only twenty-five per cent. of its mass. All these experiments go to prove the fact, that while the cell, the nucleus and the nucleolus lead an existence in common, it is nevertheless variable in each.

Loukianoff described his own experiments concerning the change produced in the cell and its nucleus by various forms of starvation. Twenty animals (white mice, as they seem the least influenced by change in food) were subdivided into six groups; some were deprived of both food and drink, three were fed on tallow, three on egg-albumin, three on peptones and three on oats; thus some animals were subjected to absolute starvation, some fed exclusively on fat, others on nitrogenous food, and others on albumin. The experimentation investigated the changes in the longitudinal and transverse diameters of the hepatic cell. The number of these measurements (about 2,000) are sufficient to draw more or less definite conclusions from. The cellular nucleus diminishes from fasting, but this diminution is not related directly to the changes which take place in the organism.

While suffering as much as the organism from complete starvation, the nucleus presents changes different from those found in the organism in cases of partial starvation, as expressed in the predominance of nitrogenous, albuminous or fatty food. The biological autonomy of the nucleus is also evidenced from another fact: the one or the other kind of inanition influences the formation of double nuclei, but this division of the nucleus into two parts does not run parallel with the changes of nutrition, as experienced by the nucleus, nor does it have anything in common with the alteration observed in the organism.

All these facts point to an independent existence of the nucleus. Of this existence we know but little, and there is here a desirable field for careful study and research.

MEDICAL NOTES.

CIGARETTE SMOKING IN JAPAN is reported to be on the increase. Every month 13,000,000 imported and 52,000,000 native cigarettes are being consumed. Women and children smoke almost as much as men.

A MONUMENT TO MALPIGHI.—On September 8th the inauguration of a monument to Francesco Malpighi took place at Crevalcore, a small town near Bologna, where the great anatomist was born in the year 1628.

"DOUGLASITIS."—Fresh barbarisms in medical nomenclature are coined almost daily. One of the new ones is "Douglasitis," put forward in the French form of "Douglasite" by Hussenstein (*Gazette hebdomadaire de médecine et de chirurgie*, 1896, No. 92) and translated into German—as a *reductio ad absurdum*,

let us hope—by Dr. Rech, of Cologne (*Centralblatt für Gynäkologie*, August 14, 1897). as "Entzündung des Douglas" (inflammation of the Douglas).—*New York Medical Journal*.

THE X-RAYS ON WAR SERVICE.—An x-ray apparatus was recently sent to Malakand. This is, according to the *British Medical Journal*, possibly the first time the apparatus has been used on field service with British troops.

THE ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA for 1897 has been awarded to Dr. Joseph Collius, of New York City, for an essay entitled "Aphasia: A Contribution and Critical Study."

HOSPITAL SHIPS.—The Red Cross Society of Japan has given orders, it is said, for the construction of two thoroughly appointed floating hospitals, of twenty-six hundred tons each, for the treatment of the wounded in time of war.

LEPROSY IN NORTH DAKOTA.—The Surgeon-General of the Marine-Hospital Service in Washington has been informed of the existence of two cases of leprosy in Walsh County, N. D. The disease is said to be well developed. Both of the patients are Scandinavians.

YELLOW FEVER IN THE SOUTH.—There has recently been an increase in the number of new cases of yellow fever reported at New Orleans, which in the opinion of the members of the Board of Health is due to the enforcement of the law requiring prompt report of cases. The work of the Board is so thoroughly carried out that there is very little danger of any cases escaping their notice, and there is no apprehension of an epidemic. The yellow fever bulletin issued by the Marine-Hospital Service on October 5th gives the following report for October 4th: New Orleans, 24 new cases, no deaths; Biloxi, 11 new cases, no deaths; Nittayuma, Miss., 2 new cases, no deaths; Edwards, 18 new cases, 2 deaths; Ocean Springs, Miss., no new cases and no deaths; Mobile, report delayed. At Scranton on the 1st, 2d and 3d there were 30 new cases, and on the 3d 2 deaths. Twenty-four refugees were admitted to the camp at Fontainebleau yesterday and 60 discharged. Reports from Mobile, dated October 5th, stated that the authorities were successfully coping with the disease. At Cairo, Ill., there have been no further cases reported. Dr. Guiteras has been ordered to Galveston, Tex., by the Marine-Hospital Service, and whilst proceeding thither from New Orleans, via St. Louis, was at last accounts detained by quarantine officers at Houston, Tex. Such action seems at this distance grotesque, and more calculated to do harm than good; it is probably inspired by hereditary State Rights and that sense of routine duty which causes the sentry to challenge the commander-in-chief.

THE TYPHOID EPIDEMIC AT MAIDSTONE, ENGLAND.—It is reported that an alarming outbreak of typhoid fever has occurred at Maidstone, in England.

The epidemic is attributed to pollution of the water-supply by drainage from an encampment of hop-pickers, among whom several had been sick with typhoid. The medical officer of health of Maidstone reported on September 22d to his sanitary authority that 306 cases of typhoid fever had been recently notified in the borough.

DIPPING CATTLE FOR TEXAS FEVER. — It has recently been discovered that ticks were the agents by which the contagion of Texas fever is spread, and that by dipping the cattle in antiseptic solutions these pests can be gotten rid of. At the Agricultural Experiment Station of the Missouri State University at Columbia, Mo., Mr. Kleberg, Superintendent of the Santa Gertrude Ranch, constructed a vat large enough to allow the immersion of a full-grown animal. The cattle are dipped in a mixture of oils containing a little carbolic acid. The Department of Animal Industry is conducting similar experiments at Fort Worth, Texas, where the cattle are being dipped in chloro-naphthol.

THE TRANSPOSITION OF THE VISCERA DEMONSTRATED BY THE RÖNTGEN RAYS. — Burghardt¹ publishes an account of the case of a woman nineteen years old, in whose case he made a diagnosis of *situs viscerum transversus*, which was confirmed by a skiagram reproduced in the article. The skiagram shows distinctly the liver on the left and the heart and fundus of the stomach on the right. An interesting point about the case is that Burghardt and his colleagues ausculted the heart on the left side, supposing it to be in its normal position, and the sounds were so well transmitted by the chest wall, that no abnormality was noted. Burghardt at the second examination noted the apex beat could not be felt in its normal position, and discerned it in the right mamillary line. Further investigation established transposition of the abdominal organs.

DEVOTION OF A DOCTOR. — The *Times of India*, in an interesting account of the attack on the Malakand, speaking of the fight on July 28th, gives the following description of the devotion of a medical officer: "The casualties in the 31st Punjab Infantry were very heavy, two killed and twenty-one wounded, including Lieutenant Ford and Lieutenant Swinley, the former very severely. In fact it was entirely due to Surgeon-Lieutenant Hugo's perseverance that Ford's life was saved; with the greatest difficulty the bleeding was stopped, Hugo holding on to the arteries with his fingers for some hours." Surgeon-Lieutenant James Henry Hugo, we learn from the *British Medical Journal*, of the Indian Medical Service, who is M.D. of London University, had a distinguished career both at St. Bartholomew's and at Netley, where he won the second Montefiore Medal in Military Surgery. How in the face of such instances as this, and they are not rare, the officers of the British Army can persist in their unfair and contemptuous treatment of the medical service it is difficult to understand. A more astonishing fact, however, is that under the conditions

men of the Hugo type are found willing to undertake the labors and risks of the Army Medical Service.

THE MEDICAL DEPARTMENT OF THE BRITISH ARMY. — The *Practitioner* voices the sentiment of the of the British profession with regard to army medical service as follows: "The complaint about the boycotting of the Army by the doctors, which have recently been made in Parliament and in certain newspapers, are to the last degree disingenuous. The Army, as represented by its combatant officers, seems to take a special pleasure in boycotting the doctors, and it is surely not to be wondered at that doctors who have any regard for their own dignity should not care to expose themselves to such treatment. As things are, the Army for the most part gets the mere refuse of the profession, and it will never get anything else while the present system of official snubbing of medical officers on every possible occasion, and of treating them as in a military sense "camp followers," and socially as unfit to come between the wind and the combatant's nobility, is allowed to continue. Till the Army doctor is given military rank with its full privileges, and is recognized not merely *de jure*, but *de facto*, as an officer and a gentleman, and treated as such, it is the duty of the teachers in the medical schools and of every member of the profession who is in a position of influence to recommend young medical men not to enter the Army Medical Department. Why one of the leading medical journals should be so vehement in denying that this is an 'Army medical boycott' is not clear. The name given to the process, however, matters nothing. Let us call it 'abstention' if that sounds better. The important thing is to get youngsters to 'abstain' from putting on the livery of degrading servitude into which the War Office has transformed the Queen's uniform as far as doctors are concerned."

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, October 6, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 47, scarlet fever 23, measles 5, typhoid fever 34.

AMERICAN DERMATOLOGY. — Dr. J. C. White, of Boston, was appointed to make the report to the International Congress of Leprology, on Leprosy in North America. The Congress will be opened in Berlin next week, October 11th. Mr. Malcolm Morris, President of the Dermatological Section of the British Medical Association, in his opening address before the Section, alluded to Dr. White's relation to dermatology in America in very handsome and well-deserved terms of appreciation. In regard to leprosy, Dr. White has long been regarded as the leading authority in this country.

THE NEW BUILDING FOR THE EYE AND EAR INFIRMARY. — Plans for the new building to be erected in Charles Street, West End, for the use of the Massa-

¹ Deutschr. med. Woch., 1899, No. 38.

chusetts Eye and Ear Infirmary, have been filed by Messrs. Shaw & Hunnewell. The plans are for a building of fireproof construction throughout, four stories high, with a frontage of 124 feet and a depth of 172 feet. The building will be thoroughly equipped in every respect.

NEW YORK.

CONTINUED LOW MORTALITY.—The low mortality still continues in the city, although there was some increase last week over the preceding week. During the week ending September 25th there were reported 664 deaths. Of these 2 were from measles, 3 from scarlet fever, 20 from diphtheria, 7 from whooping-cough, 9 from typhoid fever, 4 from cerebro-spinal meningitis, 2 from croup, 30 from Bright's disease, 50 from pneumonia, and 82 from pulmonary tuberculosis. There were 67 from diarrheal diseases, of which 59 were of children under five years of age. In the week ending October 2d, the deaths numbered 710. Of these, 5 were from scarlet fever, 17 from diphtheria, 1 from measles, 5 from whooping-cough, 4 from typhoid fever, 1 from cerebro-spinal meningitis, 47 from Bright's disease, 2 from croup, 57 from pneumonia, and 107 from pulmonary tuberculosis. Of 54 deaths from diarrheal diseases, 53 were of children under five years of age. The increase in the number of deaths will thus be seen to be largely due to the increased mortality from consumption and pneumonia.

A WOMAN BECOMES A VETERINARY SURGEON.—When the New York College of Veterinary Surgeons commenced its autumn and winter session during the past week, one of the matriculants was Miss Susan J. Brayton, of Easton, N. Y., whose father is the owner of a large stock farm. She is said to be the first woman to adopt the profession of veterinary surgeon, not only on this continent, but in the world.

CITIES AND THEIR MILK-SUPPLY.—Among the papers read before the national conference of Mayors and Councilmen held at Columbus, O., during the last week of September, was one on "The Influence of a Pure Milk-supply on the Death-rate of Children," by Nathan Strauss, of New York, the founder of the depots for the supply of sterilized milk to the poor. In the course of it, he said: "There is practically no milk delivered for general consumption in cities that is fit to be fed in its natural state to young children." After having given a large number of mortality statistics and outlined the work done by him in establishing pure-milk stations in the city of New York, he went on to say: "I think I have fairly demonstrated the proposition that many thousands of infant lives are annually sacrificed by the neglect to supply for the nutriment of children milk which has been sterilized. I hold that neglect to be criminal, and I leave it to you to fix the responsibility for it. We punish murder with the penalty of death, and yet we allow murder to be committed by the wholesale in every populous community of this land, with no thought of its punishment and little thought of its prevention."

Miscellany.

DUCHENNE.

UNDER the editorship of Dr. Geo. Gautier there have just been published¹ the orations delivered at the inauguration of the monument recently erected at the Salpêtrière to the memory of Duchenne, of Boulogne. The ceremony took place on Sunday, June 27th, under the presidency of the Minister of the Interior. It was claimed for Duchenne that in the domain of neuro-muscular pathology, of the physiology of movement, and of the therapeutic applications of electricity he had literally evolved order out of chaos. To him we owe the axiom that the nutrition of the muscle depends on the cells, or on certain cells, of the anterior cornua of the cord. His classic investigations on the nature of "the atrophic paralysis of infancy," of atrophic spinal paralysis in the adult, of progressive muscular atrophy, and of locomotor ataxy were eloquently referred to. His life had been that of a modest man of science; he had known neither honors nor rewards; he was not a member of the Institute or of the Academy of Medicine. The presence of delegates from these learned bodies on that day seemed like an expression of regret that they could not claim him as one of them. That monument and that day's celebration were not only an act of justice, but also an act of reparation.

THE ADULTERATION OF FOOD AND DRUGS.

By direction of Congress, the Department of Agriculture is investigating the character and extent of the adulteration of foods and drugs. It is generally believed that adulteration, sophistication, imitation, and misbranding of foods, drugs, and liquors exist to a very great extent. Many of the States have enacted laws to prevent such practices, and it is very desirable to know how these laws have been enforced, and with what results.

As the general public is largely interested in this matter, as it affects health, morals and legitimate trade, it is thought proper to ask the co-operation of the press in securing accurate information on the subject.

In accordance with these ideas the following letter has been put in circulation:

WASHINGTON, D. C., September 17, 1897.

DEAR SIR:—Under authority of Congress, the Department of Agriculture is investigating the extent and character of food and drug adulterations, and is desirous of securing all the information possible on the subject. Having been appointed special agent to inquire into and report upon this matter, the undersigned writes to request that you kindly furnish the Department (under the inclosed franks) all the information you have in regard to adulterations, together with any suggestions as to the best remedy for the evil.

(1) Do you know of any new adulterant? If yes, state what, and how used.

(2) Would a national food and drug law assist in preventing adulteration?

(3) Would uniform food, drug and pharmaceutical laws tend to promote efficiency and purity?

(4) Please suggest what would best promote the interests of consumers and legitimate manufacturers and dealers.

(5) What is your opinion as to the extent of damage done legitimate business by imitation of brands, packages, etc.?

¹ The Lancet, London.

(6) To what extent do sophistication, misbranding and injurious adulteration exist?

(7) Have State laws aided in preventing adulteration? To what extent?

(8) Would a national law assist State officials in properly executing the local laws?

(9) Have adulteration, sophistication and misbranding increased or decreased?

Prompt replies to the above, together with any other information or suggestions, will be highly appreciated.

Yours respectfully,

A. J. WEDDERBURN, *Special Agent.*

It is understood that the Department simply desires a concise statement of facts, which can be fully substantiated, if necessary, and not theories.

Correspondence.

A CASE OF MOON-BLINDNESS.

61 DARTMOUTH STREET, BOSTON,
September 28, 1897.

MR. EDITOR:—In the *New York Medical Journal* of the 18th inst. I noticed a report of a case of moon-blindness, which had come under the observation of a Norwegian physician. This led me to make inquiries, and finding that the disease is of rare occurrence, I thought that the following account of my brother's case might be of interest:

The first week of May, 1895, my brother (then a sailor, seventeen years of age) sailed from the Argentine Republic, bound for Norway. In the night those of the watch who were not on the lookout or at the wheel were in the habit of sleeping on the fore-hatch, being careful to protect their eyes from the rays of the moon. One night in the first week of June, between the equator and 5° N. Lat., my brother had been asleep for some time between 2 and 4 A. M., and in his sleep had uncovered his face. He noticed nothing out of the common until between 7 and 8 o'clock in the evening, when he had difficulty in finding his way about on the deck, even walking into other members of the crew who happened to come in his way. On remarking to one of the crew what a dark evening it was, he was surprised to be told that the moon and stars were shining bright. When he came on deck again at midnight, his sight was somewhat better, but the following evening he could distinguish nothing after sunset. For about a week he went about his duties as best he could, being able to see perfectly well between sunrise and sunset, and experiencing no difficulty then, except that sometimes shadows and flashes seemed to pass in front of his eyes. After sunset, however, he was unable to locate any object, although he was able to see it, that is, he could see nothing straight ahead, but could make out objects at the side of his line of vision, although he did not know just where they were. He was then ordered to tie something around his eyes and to remain in the fore-castle (none too light at best), bathing his eyes with sea-water at frequent intervals. In this fashion he spent about ten days, but with no apparent improvement. The ship was then off the Azores, and from that time until they reached Norway, about July 15th, he used to work all day, and sleep at night. In Norway the crew left the ship, my brother going by steamer to his home in southern Sweden. His impairment of vision was still so pronounced that he could not find his way about on board the steamer, or distinguish anything in the evening. Shortly after reaching home he noticed that an improvement had set in, and about five weeks later, when he left Sweden to come to Boston, he was not conscious of any defect of vision.

His eyes are now in very good condition, as far as can be made out without special examination. The pupils respond readily to light, but they seem rather large, and when he looks at distant objects there is a certain "Je ne

sais quoi," as though he tried to open his eyes more than usual.

I have thought that ophthalmologists might be looking up cases of moon-blindness, and would be glad to learn of this case.

Yours truly,

IVAN A. CENTERVALL.

METEOROLOGICAL RECORD

For the week ending September 25th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Amesbury	10,920	—	—	—	—	—	—	—	

Deaths reported 2,165; under five years of age 867; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 356, consumption 241, acute lung diseases 142, diarrheal diseases 187, diphtheria and croup 73, typhoid fever

47, whooping-cough 18, cerebro-spinal meningitis 15, scarlet fever 5, measles and malarial fever 4 each.

From whooping-cough New York 7, Philadelphia 6, Lowell 2, St. Louis, Baltimore and Chelsea 1 each. From cerebro-spinal meningitis Boston 6, St. Louis and New York 4 each, Worcester 1. From scarlet fever New York 3, Philadelphia and St. Louis 1 each. From measles New York and Providence 2 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending September 18th, the death-rate was 18.5. Deaths reported 3,900, diarrhea 454, whooping-cough 64, fever 54, measles 53, diphtheria 49, scarlet fever 47.

The death-rates ranged from 10.7 in Cardiff to 29.8 in Salford; Birmingham 22.3, Bradford 17.6, Bristol 13.2, Gateshead 20.1, Huddersfield 14.9, Leeds 20.5, Leicester 20.0, Liverpool 24.1, London 16.1, Manchester 22.8, Newcastle-on-Tyne 20.9, Nottingham 16.6, Portsmouth 15.7, Sheffield 22.2.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 25, 1897, TO OCTOBER 1, 1897.

COLONEL CHARLES R. GREENLEAF, assistant surgeon-general, will, in addition to his present duties in charge of the Medical Supply Depot in San Francisco, Cal., take charge of the office of the chief surgeon, Dept. of Cal., during the absence on leave of the chief surgeon.

CAPTAIN ROBERT J. GIBSON, assistant surgeon, Fort Thomas, Ky., is ordered to report to the president of the examining board at Surgeon-General's Office, Washington, D. C., October 4, 1897, for examination for promotion.

FIRST-LIEUT. HENRY R. STILES, assistant surgeon, Fort Preble, Me., ordered to report to the president of examining board at Washington, D. C., October 18, 1897, for examination for promotion.

CAPTAINS CHARLES RICHARD and GEORGE MCCREERY, assistant surgeons, ordered to report October 4, 1897, to the president of the examining board, appointed to meet at the Surgeon-General's Office, Washington, D. C., for examination for promotion.

MAJOR CHARLES B. BYRNE, surgeon, is relieved from duty at Fort Snelling, Minn., and ordered to Plattsburg Barracks, N. Y., for duty.

MAJOR PHILIP F. HARVEY, surgeon, on being relieved from duty at Plattsburg Barracks, N. Y., is ordered to Fort Snelling, Minn., for duty.

CAPTAIN JEFFERSON D. POINDEXTER, assistant surgeon, now at Willets Point, is ordered to temporary duty as attending surgeon and examiner of recruits in New York City, relieving CAPTAIN CHARLES RICHARD, assistant surgeon, who is ordered to Fort Monroe, Va., for duty.

A board of officers to consist of COLONEL CHARLES R. GREENLEAF, assistant surgeon-general, MAJOR EDWARD B. MOSLEY, surgeon, CAPTAIN EUCLID B. FRICK, assistant surgeon, is appointed to meet at Hdqrs., Dept. of California, San Francisco, Cal., on Monday, October 25, 1897, for examination for promotion of officers of the medical department.

CAPTAIN PAUL F. STRAUB, assistant surgeon, Angel Island, Cal., ordered to report to the president of the examining board, San Francisco, Cal., October 25, 1897, for examination for promotion.

A board of officers to consist of LIEUT.-COL. ALFRED A. WOODHULL, deputy surgeon-general, MAJOR CURTIS E. MUNN, surgeon, CAPTAIN WILLIAM F. LIPPITT, JR., assistant surgeon, is appointed to meet at Hdqrs., Department of the Colorado, Denver, Col., Monday, October 18, 1897, for the examination of medical officers for promotion.

FIRST-LIEUT. HARRY M. HALLOCK, assistant surgeon, will report to the president of the examining board at Denver, Col., October 18, 1897, for examination for promotion.

A board of officers to consist of LIEUT.-COL. HENRY R. TILTON, deputy surgeon-general, CAPTAIN WILLIAM C. BORDEN, assistant surgeon, CAPTAIN HENRY A. SHAW, assistant surgeon, is appointed to meet at Hdqrs., Department of Dakota, St. Paul, Minn., on Monday, October 18, 1897, for examination of medical officers for promotion.

FIRST-LIEUT. GEORGE J. NEWGARDEN, assistant surgeon, ordered to report to the president of examining board, St. Paul, Minn., October 18, 1897, for examination for promotion.

The order directing FIRST-LIEUT. WILLIAM F. LEWIS, assistant surgeon, to report for duty at Fort McPherson, Ga., is amended so as to direct him to report for duty at the new post on Sullivan's Island, S. C.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING SEPTEMBER 25, 1897.

WHEELER, W. A., surgeon. To proceed to St. Louis, Mo., and assume temporary command of Service. September 20, 1897.

BRATTON, W. D., passed assistant surgeon. Relieved from waiting orders and directed to proceed to Sabine Pass, Tex., for special duty. September 20, 1897.

MAGRUDER, G. M., passed assistant surgeon. When relieved by Passed Assistant Surgeon W. D. BRATTON, to proceed to Galveston, Tex., and await orders. September 20, 1897.

CORB, J. O., passed assistant surgeon. To proceed to Cairo, Ill., for special duty. September 20, 1897.

RECENT DEATHS.

IRA LORISTON MOORE, M.D., M.M.S.S., died in Boston, October 2, 1897, aged seventy-two years.

ALARIC FRITHIOF HOLMGREN, M.D., professor of physiology in the University of Upsala, and founder of the first Physiological Institute in Sweden, has recently died at the age of sixty-six years. He studied at Upsala and later practised as a physician, and represented his Government in connection with various International Cholera Commissions. He graduated as M.D. in Upsala in 1861, and in the same year he was appointed assistant in theoretical and practical medicine in that University. About this time there was a marked awakening as to the need for the foundation of better laboratories in Sweden, so that in 1862 Holmgren was commissioned to spend some years abroad to study physiology as it is taught by the great European masters. At Vienna in 1862 he studied under Ludwig. The outcome of these studies was one of the earliest of that long series of papers on respiratory exchanges, a theme which Ludwig pursued incessantly through his pupils. It was entitled "Mechanismus des Gasaustausches bei der Respiration" (*Wiener Akademie*, 1862). Until 1864 he studied under Brücke, du Bois Reymond, and Helmholtz; while he also visited the schools of Paris, London and Italy. In 1864 he was elected professor of physiology in Upsala, and built there the first physiological institute in Sweden.

His scientific work ranges over a wide field, including his researches on "The Negative Variation of the Muscle Current" (1862), a similar condition in the active heart (1864); the action of poisons, calabar bean, chloroform and atropine; the use of the ophthalmometer, and studies in color sensation. Perhaps his best known works are those on "Retinal Currents" (*Centralblatt*, 1865, and Heidelberg, 1873). In 1878 he published his well-known work on "Color Blindness in Relation to Railways and the Navy," thus bringing to a practical issue the work long before begun by George Wilson, of Edinburgh (1855). This led him to the invention of his now well-known "worsted test" for color vision.

In 1889 he founded and became the editor of the *Skandinavisches Archiv für Physiologie*, as he says in the preface "not only to unite our scattered forces under one flag," but to gain a powerful impulse for the advancement of the science in the north of Europe.

At the Liège and Berne meetings of the Physiological Congress by universal consent he was perennial President. Holmgren amongst his compatriots had other claims to fame. His literary talents were great, and he was well known as a gifted poet. His speeches always had something of the poetic vein in them, thus lending a particular charm to his utterances on public occasions.

TWO CASES OF HOMICIDAL, AMNESIC, TRANSITORY FRENZY.¹

BY CHARLES P. BANCROFT, M.D.,
Superintendent New Hampshire Asylum for the Insane.

No cases are more puzzling to the medico-legal specialist than those homicidal individuals who steadfastly persist that they have no recollection of the acts of violence with which they are charged. The man who has committed a homicide and then insists that the period in which the act was done was all a blank to him, and positively refuses to admit anything concerning the occurrence of the deed both at the time and for a longer or shorter period subsequently — such a man places himself in a position from which it is difficult to dislodge him. Savage has very pertinently called attention to the difficulty of proving sanity where the individual consistently and persistently asserts utter lack of knowledge of the acts which he is known to have committed.

The fact remains that cases of homicidal and suicidal violence do occur in which the individual does in all probability commit the act automatically, retaining no subsequent recollection of the fearful crime he has perpetrated. Fortunately, such cases are rare. They are psychologically intensely interesting and deserve most careful study. Not unfrequently the perpetrator of some precipitate homicide pleads amnesia. When, as is often the case, aggravating circumstances coexist and seem to furnish an incentive for the crime, then it becomes very important to present a clear analysis of the person's psychic state at the time the crime was committed with a view to determine whether he is malingering, or whether his rash act was the outgrowth of some psychic explosion over which he had no control and of which he may have been wholly unconscious.

All these cases of amnesic homicidal frenzy lead into that extremely interesting and ever-broadening domain of consciousness, personality and memory which has been studied so carefully during the past few years. Before discussing any possible explanations of these strange psychological states, I desire, as briefly as possible, to call attention to two cases of homicidal frenzy that have come under the writer's observation — one of whom is still under his care in the New Hampshire Asylum. There seems no reason for doubting the amnesia which succeeded the homicidal explosion.

CASE I. G. W., male, forty-seven years of age, married. Patient's ancestry decidedly neurotic. His father was insane and a patient at the New Hampshire Asylum. A paternal uncle and aunt and one sister have also been insane. Patient himself has always been of a suspicious, jealous disposition, rather inclined to be solitary and unsocial. When quite a young man was at one time very intemperate, but soon renounced this habit and for over twenty years has never been known to indulge in liquor, and has strenuously opposed its indulgence in others. Was always an industrious man working steadily on the railroad as a section-hand or in a lumber-yard. Contracted a most unfortunate marriage with a woman wholly incompatible with him. For years they quarrelled with each

other, mutually agreeing to separate, but always coming together again and renewing their promises to live without enmity, but invariably coming to mutual re-crimination. Five daughters were the result of this unhappy union. The patient's wife cared as little for her home as for her husband, and in the course of time began to be intimate with another man. When the oldest daughter had reached the age of seventeen years the mother deliberately encouraged her entering a road-house which she hired and which she finally lived in — separating herself entirely from her husband and the other children, who lived with their father in the original homestead. The next oldest daughter when about fifteen years of age gradually began to visit the mother and her elder sister in their new location, which was in an adjoining town.

The knowledge of these facts goaded W. to desperation. He pleaded with his oldest daughter and with his wife, who in her most unnatural course seemed to take delight in tormenting him. For over a year the patient seemed to be growing more and more depressed and gloomy. He became excessively religious — reading the Bible a great deal, although he attended no church regularly.

Gradually it was noticed that he was out very late nights; quite frequently he would visit the adjoining town and remain several hours outside the house where his wife and eldest daughter lived, carefully watching the place, but never making any attempt to enter. Oftentimes he would be met as late as one or two o'clock in the morning returning home. On these occasions it was noticed that he would skulk behind trees, casting furtive glances over his shoulder, as though he feared he was pursued. He became irregular at his work, and the owner of the mill where he was employed did not expect him more than one or two days out of the week.

Finally, his wife procured counsel and sought to get a divorce from the court. This seemed to inspire W. with a new dread. He feared his wife would get a separation from him and procure the custody of the children and then plunge them all in a life of prostitution.

It was while in the midst of these horrible dreads, which were unfortunately only too real, that he met one morning at the railway station his wife with one of the youngest girls, about five years of age, on her way to the court. Several people were awaiting the train and noticed his strange actions. For several moments he tried to secure an interview with his wife, who dodged about the station, passing out of one door, while he entered another, thus trying to avoid him in every possible way. At last he came up with her on the platform. The people noticed him pleading earnestly with her and the child, finally drawing them both off from the platform and out in the street. Both were talking earnestly but in subdued tones. Suddenly to the horror of the spectators W. was seen to draw out a dirk knife from his breast-pocket and nearly sever his wife's head from her body. Again and again he plunged the bloody blade in her breast. The bystanders surrounded him. He fell on his knees, pale and trembling, with his eyes wild and staring. He made no remarks and no opposition toward being led away. He was hurried off to jail.

In the course of a few weeks I was summoned, with Dr. G. F. Jelly, to examine him while in the jail with reference to his insanity. His hands were cold and

¹ Read before the Boston Medico-Psychological Society April 15, 1897.

clammy. Pulse rather weak and rapid. His face pinched and haggard. His eyes wild and staring. The mucus would run from his nose without much attention from him. He would stand first on one foot, then on the other, always picking at his coat, which he had worn away for several inches by this constant unravelling of the threads with his fingers. He was not inclined to talk, but would moan and ask for his daughters. He always referred to his wife as though she were living with another man. The way in which he spoke of his wife impressed one with the idea that he honestly thought she was living.

When finally charged with the murder openly, he appeared surprised, and said it was impossible. He recalled the events of the morning of the homicide, saying he remembered that he went to the station to plead with his wife not to get a divorce and take away his daughters. He remembered being distracted with a flood of conflicting emotions, fear for his own life, dread and horror for the fate of his daughters, anguish over the course his wife was pursuing. Suddenly, he said, all turned dark; he seemed to be in a whirl of confusion, and all he could recall was a struggle and a crowd of men pressing upon him.

In whatever way he was cross-questioned he always persisted, and to this day still persists in telling the above story in the same way. When asked why he was armed as he was with knife and revolver, he always replied that for a year he had feared some one was going to jump on him from behind and murder him. He thought this foe was the man with whom his wife was intimate, and that failing in getting a divorce it was their intention to kill him. This idea he had at different times, during the year previous, confidentially told friends of his. There is little doubt that he honestly believed it, and always went armed in self-defence on account of this delusion. This idea also explains his hurried gait, anxious glances over his shoulder, and the dodging behind trees at night. It also furnishes a reason for his being armed on the morning of the homicide — that fact not necessarily, therefore, implying premeditation.

It is a significant fact, and one to which we shall allude later, that he made no remark after the homicide, or ever alluded to it in any way. As far as any expression of knowledge of the homicidal act itself he never manifested anything either by word or look. That occurrence to all appearances was a blank. For many months he strenuously denied its possibility, insisting that he believed his wife was living with another man. Finally and at the present time, he admits, that as every one declares that he did kill his wife, it must be true, although he has not the faintest recollection of having done such a thing.

After careful examination, Dr. Jelly and myself both concluded that the man was insane and that there was no reasonable doubt that his psychic state was such at the moment of the homicide that he had no conception, no realization in consciousness of his homicidal act, and consequently no recollection afterward of what he had done. Upon our statement the grand jury refused to indict him and he was ordered to the New Hampshire Asylum by the Supreme Court.

A singular occurrence took place while he was in the jail. As shown by a photograph of the prisoner, he wore a long, heavy beard. One morning the guard at about seven o'clock passed in his breakfast to him. At that time W. appeared as usual with his blank stare,

his long beard somewhat disheveled. About two or three hours later the guard returned to his cell for his empty breakfast dishes. To his surprise W's beard had disappeared and lay scattered about his cell. It was evident that in the interim between the serving of his breakfast and the removal of the dishes he had entirely plucked it out. W. professed entire ignorance of the fact, and to this day insists that he has no recollection whatever of having done such a thing. The query suggests itself whether this sudden depilation was not a frenzy attended with amnesia similarly as was the homicide.

W. was admitted into the asylum on the 4th of October, 1892. About two weeks after admission the case-book says: "He either sits or lies on a settee from morning until night, picking his clothing. Looks pretty thoroughly demented. Never speaks or looks up except when spoken to, and then pays no attention to what is said to him, but begs to know if his children are still living." Nearly a year afterwards, August 23, 1893, the case-book says: "Mental and physical condition unchanged. He is still very restless, picking his clothing or pulling at his beard, or walking the floor. He often asks if we know whether or not his children are alive and where they are. He seems to think of nothing else but his children." He always picked his clothing in one place and it was necessary to renew his coat often because he wore it out. The picking has become in fact an automatic habit, so characteristic of many demented and chronic insane patients.

From this date, August, 1893, W. gradually improved mentally and physically. He lost the blank, vacant stare, ceased the automatic picking at his clothing, and the nervous walking the floor. He gained in flesh and color. He would write long letters to his children; and in these spoke of the violent death of his wife as though he did it in a frenzy without knowing what he was doing. He has undoubtedly reached the best possible mental condition that can be expected in his case. He admits that he must have killed his wife, not because he recollects it, but simply because others say he did.

CASE II. S. P., French-Canadian, age seventy-nine years. Admitted to the New Hampshire Asylum, May 14, 1890. In earlier life the patient had been a very hard drinker, but for some years had not taken any liquor to excess. For some months past has had delusions of suspicion and fear, attended by hallucinations of hearing. He has two sons, and he has thought that one of them was going to kill him. These sons both lived in different towns and the one that he feared was the one with whom he lived. There was no reason whatever for his suspicion, the son in question doing all that he could for his father, and trying in every way to disarm him of his fears, but without avail. Finally, it was thought best for him to go and live with his other son, who was a farmer and against whom he entertained no fear whatever.

He did not, after his removal, change in his attitude toward the first son. He would say that he knew he would come up and kill him. The family often noticed him out in the orchard looking behind trees and over his shoulder, as though he thought some one was approaching him from behind. He desired the family to keep the gun loaded, and the doors and windows securely fastened. It may be said that he was very deaf and this fact served to increase the fear induced by his

hallucinations. A slight touch, as of any one accidentally brushing against him from behind, always startled him and intensified the fear that he seemed to be continually laboring under.

One day he was sitting in the kitchen. His grandchildren, a little boy about six years of age, and a girl about thirteen years of whom he was very fond and proud, were sitting on the floor bounding a ball between them. They would throw the ball on the floor making it bound up to the ceiling and back again to one another. The old man sat in a chair with his back toward them, apparently having no thought of the children. The ball with which they were playing was a very light one. Suddenly it glanced back from the ceiling striking the patient on the head. Instantly he started up in a frenzy of fear and excitement, seized a small hatchet that happened to be near and rushing furiously toward the little boy struck him on the head fracturing his skull and killing him instantly. The little girl ran for the door screaming, but her grandfather reached her, made two or three slashes on her neck, shoulder and her scalp behind the ear. Fortunately the wounds were not deep enough to kill her and she eventually recovered. After inflicting these wounds on the girl he rushed out wildly into the road. The cries of the girl had attracted the attention of the neighbors who lived opposite and who ran out to ascertain the trouble. They found S. P. panting with fear and excitement, talking disconnectedly and apparently much dazed. He had not been drinking, and apparently, so the neighbors said, had no realization nor recollection of what he had done. It is to be noted here that he did not at the time make any allusion to the homicidal act, nor ever afterward has he ever alluded to it. The entire occurrence was a blank to him.

A few weeks afterwards I saw him in jail. He protested that he remembered nothing of the fact of having killed his grandchild. He said he loved him too dearly to have done such a thing. He evidently was deeply deluded and disturbed by the same fears and hallucinations as when at home. Once when in jail he attempted suicide by hanging and was barely cut down in time by the jailer to save his life.

Two examinations made at different times in the jail convinced me that the man had been for a long time, and was then insane, and that he committed the homicide in a frenzy of fear and excitement—his psychic state being such that he had no realization of what he was doing at the time, and no subsequent recollection of anything that occurred during the period he was in that state of mind. He was ordered to the New Hampshire Asylum, where he has remained ever since.

His condition at the asylum is one of chronic delusional insanity, attended with ideas of fear and depression. At one time he attempted suicide by hanging but was rescued in time to save his life. He has always protested his innocence but, like the previous case, admits that it must be so as every one tells him that he killed the child.

Several times while in the asylum he has started up suddenly in a state of mingled fear and anger when some other patient has accidentally touched him from behind before being seen by him. He is so deaf that it often happens that some one gets near him without being noticed by him. Then a mere accidental touch of a coat sleeve is sufficient to excite him to quite a degree.

It only remains to add to the history of these cases

that in neither of them was there ever any record of epilepsy in any of its forms.

In analyzing the mental condition of these cases it is evident that in each we have a fulminating psychosis engrafted on a permanently more or less deranged state of mind. Both individuals belonged to the melancholia type. They were filled with delusions of fear and suspicion, and were both depressed as a result of their forebodings.

In the case of the old man, S. P., the fears were entirely groundless and based on his insane imagination. In the case of G. W. a most unfortunate and deplorable state of affairs really existed and undoubtedly induced a condition of permanent morbid suspicion and fear in a mind hereditarily predisposed to alienation.

The psychological interest and medico-legal importance attaching to such cases lead us to query as to their pathology. How is absence of consciousness to be accounted for? Does the fact of absence of consciousness necessarily imply epilepsy? Is there a condition of mind that can be called transitory frenzy, in which the individual acts automatically, performing the most desperate homicidal acts without once realizing what he is doing, and instantly losing all recollection of everything that transpired during this period?

Concerning this matter of consciousness in connection with homicidal acts there has been among writers a difference of opinion. W. Bevan Lewis says: "In the genuine impulsive forms of insanity consciousness is never so far impaired as to issue in forgetfulness of the details of the homicidal act. When such is the case—when any marked obscuration of memory is apparent—we may presume the impulse to have been of epileptic origin, or to be the outcome of alcoholic delirium."²

Dr. Echeverria³ declares there is no such thing as transitory mania. All attacks of this sort on close examination "prove to be unsuspected epilepsy or epileptic insanity."⁴ An investigation into these cases he thinks will reveal "epileptic disease in its hidden varieties, such as nocturnal fits or simple vertigo."

Maudsley, while recognizing the epileptic origin of most cases of homicidal frenzy, still thinks we must admit that "there are some cases in which there is no evidence of epilepsy in any of its forms to be found"; adding, "but it may well be doubted whether a distinct insane neurosis is not always present in these cases."⁵

Griesinger believes that attacks of homicidal fury may suddenly declare themselves in the midst of a mild melancholia, in which there may be an obscuring of consciousness, and a "determination to massacre and slay all who come in his way." He regards the mental condition as very analogous to "those sudden fits of profound anxiety and severe mental suffering which have sometimes been witnessed as precursors of epileptic attacks."⁶

Clouston believes it is possible for the normal inhibitory power to be so weakened by disease that the individual may be irresistibly impelled to the commitment of murder and other criminal acts. He says, "It is our duty as medical men to examine carefully

² W. Bevan Lewis: *Text-Book of Mental Diseases*, p. 184.

³ *American Journal of Insanity* for July, 1873.

⁴ *Loc. cit.*, vol. xxx, p. 18.

⁶ Griesinger: *Mental Diseases*, pp. 263, 264.

the evidence in every case where a homicidal-impulse theory is set up to explain crime, to look on any such case suspiciously perhaps, to search for other symptoms and causes of mental or nervous disease accompanying it, but we must not be frightened by the lawyers into blinking at real facts and real disease." Clouston believes there is such a condition as *epileptiform impulse* in which there are sudden impulsive acts attended by unconsciousness, which are exactly the same in character as those we are familiar with in epileptics, and yet the patients are not subject to ordinary epilepsy.⁷

Spitzka gives perhaps the clearest account of transitory frenzy. He frankly admits that such a condition may occur in persons to all appearances perfectly sane, although it is usually induced by worry, vexation, prolonged insomnia, and violent emotional and intellectual strain. He calls attention to the suspension of consciousness and subsequent amnesia that always characterize these attacks. He does not regard them as epilepsy; on the other hand, he considers that it is more reasonable to believe that these homicidal and suicidal explosions attended with unconsciousness and amnesia may be attacks of extremely acute mania or melancholia, although he thinks that such transitory frenzy may occur in persons who just previous to and subsequent after the attack are sane.

Spitzka concludes by saying: "Those factors which lead to disturbance in the cerebral circulation of a probably congestive character are the ones active in the production of transitory frenzy. In not a few of the recorded cases the fury of the patient and his amnesia for the furious period remind one of the rage of the bull or the male elephant, conditions which are looked upon as transitory nervous disturbances in those animals, and which, like the transitory frenzy of man are, as a rule, isolated explosions in the individual's career."⁸

The amok of the Malays is a state of mind very analogous to that of the two cases just reported as well as to the impulsive psychoses the various explanations of which by different authors we have just considered. Dr. W. Gilmore Ellis⁹ regards the amok as a sort of national disease, the outgrowth of an idiosyncrasy of mind characteristic of the Malay race. This mental peculiarity is called "heart-sickness," and is itself based on a gloomy, morbid cast of mind characteristic of the race. In this condition the man broods over real or fancied wrongs, loses energy and ambition, is very despondent and forgetful. It is while in this state of mind that the amok develops suddenly, without warning. Clouding of consciousness and amnesia characterize these psychic explosions. The mental state of the amokers, both before and after the act, is quite similar to that of our cases, and it seems not unlikely that the pathology is the same in both.

In neither of the cases reported is there any record of epilepsy. For some years during their asylum residence they have been under night supervision and there has never been any evidence pointing to nocturnal epilepsy.

What, then, can be the nature of these homicidal explosions? Two factors seem to exist, namely, *unconsciousness* and *amnesia*. And in speaking of un-

consciousness it may be well to preface what we have to say by admitting at the onset the possibility of more consciousnesses than one. Subconscious states, a plurality of subconscious existences, — will receive brief consideration later. At present in speaking of loss of consciousness we will consider that we refer to the loss of that empirical consciousness which is ordinarily identified with the individual's daily existence, and, in so doing, do not by any means exclude the possibility of other less familiar but none the less possible consciousnesses.

Under what circumstances other than sleep, the toxic effects of certain drugs, epilepsy, traumatism or gross structural change can consciousness be lost? Is it possible for a man in his waking moments to suddenly lose the thread of his conscious existence and execute the most appalling crime without being aware of his acts and consequently having no subsequent recollection of what he did? What must be the physiological condition of the individual that will admit of the perpetration of such fearful deeds and yet allow so slight an impression of their occurrence to be made as to be followed by immediate amnesia?

In the somnambulistic state there are authentic cases of acts of homicidal violence, in which the individual has committed murder and retained either no recollection whatever of the deed, or a most confused and indistinct remembrance resembling some horrid nightmare rather than an actual occurrence.¹⁰

Occasionally, too, there is a *bona fide* case of sudden disappearance and dual personality in which an individual apparently sane and as well as usual, while in the midst of customary duties, without warning, enters a state of hypnotic trance and drops out of existence.

Weeks or months later he regains his normal consciousness in some distant portion of the country. The period of his disappearance is a blank to him. He ate, slept, worked and moved about among people a sort of subconscious automaton.¹¹

All such cases present a partial analogy with those referred to in this paper. It seems quite probable that the condition of the nervous mechanism in these three classes of cases — somnomania, hypnotic trance and transitory amnesic frenzy — is the same. They all possess in common the features of unconsciousness or subconsciousness, automatism and amnesia. While any statement concerning the physiological conditions underlying these phenomena must be largely speculative, still there seems good reasons for referring them all to reflex activities occurring in limited cortical areas.

The disparity between the spheres of mind and matter is so great that we continually forget that there is a most intimate connection between the two. This connection is, however, so subtle and elusive as to confuse and perplex our studies. It is only when we are confronted with some strange and very unusual psychosis, such as hypnotic trance, transitory amnesic frenzy and the like, that we realize the close relationship between functional activity of the material mechanism and psychic phenomena.

And first as to the matter of consciousness, the obscuring of which plays so prominent a part in these psychoses. Recent physiological research localizes "Conscious processes in the cerebral cortex, within

which the sensory tracts end and the motor begin."¹² Dr. Jakob also says in this same connection: "Above the reflex arc which is constituted from the two peripheral neurons, there is as it were a second arc, which is made up of the central motor and sensory neurons together with their connecting pathways in the cerebral cortex. The latter serves for the conduction from a conscious sensation to a voluntarily innervated movement, that is, for the act of the will."¹³ Unquestionably the "cortex is the sole organ of consciousness in man."¹⁴

This being the anatomical substratum of consciousness, what are the physiological conditions that underlie its manifestations? Full, complete consciousness presupposes functional integrity of the cerebral cortex. If this continuity and integrity of functions be interfered with there is very likely to result what Janet has called "a contraction of the field of consciousness." This may amount to almost complete obscuration, or even lead to alteration of the personality. In this way Binet has said that hysterical anesthesia is really anesthesia from "lack of consciousness."

It is even possible for normal consciousness to be submerged and dominated, as it were, by a subconscious condition. This subconscious condition with its power to initiate motor processes evidently has an existence and a memory of its own, for it has been successfully recalled by hypnotic suggestion, and thus demonstrated to have had an existence when the normal consciousness was suspended. Integrity of action within the cerebral cortex is thus extremely essential to normal consciousness. This is in accordance with the teaching of psychology. Professor James says: "We see that the mind is at every stage a theatre of simultaneous possibilities. Consciousness consists in the comparison of these with each other, the selection of some, and the suppression of the rest by the reinforcing and inhibiting agency of attention."¹⁵ Such comparison, selection, reinforcing and inhibition must have their organic substratum in the countless connecting neural pathways of the cerebral cortex. Normal consciousness depends upon an associative action of these various neural pathways. Consciousness will be obscured when there is defective associative action.

Closely allied to consciousness is memory. Full normal consciousness should be followed by the power to recall whatever may have transpired during its manifestation. Memory, like consciousness, depends upon integrity of action in the cortex. Like consciousness, it depends upon intensity and duration of cell activity within certain portions of the cortex. As Professor James says: "Memory being thus altogether conditioned on brain paths, its excellence in a given individual will depend partly on the number and partly on the persistence of these paths."¹⁶ Consequently dissociation of neural paths may mean interrupted and disjointed memory, just as with consciousness. Not only this, there may be memories corresponding with consciousnesses. Subconscious states may have their own special memories, which can only be recalled when by hypnotic suggestion these states themselves are reproduced. Professor James, in commenting on Janet's "theory that anesthetics carry amnesias with them," says: "In certain cases this is evidently so, the throw-

ing of certain functional brain-tracts out of gear with others, so as to dissociate their consciousness from that of the remaining brain, throws them out for both sensorial and ideational service."¹⁷

Closely related to subconscious and amnesic states is the hypnotic trance condition. Dr. Bramwell¹⁷ has written a very interesting article on the "Evolution of Hypnotic Theory," in which he briefly describes the various theories that have been advanced to account for the phenomena of hypnotism. These theories resolve themselves into two classes: one physical, the other psychical. Braid thought at one time that the hypnotic state was due to exhaustion of certain nerve centres with "resulting decrease in the functional activity of the central nervous system." Haidenhain thought "the phenomena of hypnotism owe their origin to arrested activity of the ganglion cells of the cerebral cortex." The higher cortical centres being inhibited, sensory impressions that usually pass to them, thereby arousing consciousness are in this state "short circuited" as it were through lower centres. The individual becomes an automaton, not being aware of what he is doing. At a later period Braid undertook to explain the hypnotic condition psychically, saying that it "was essentially one of mental concentration or monoidism, in which the mind was so engrossed with a single idea as to render it dead to all other influences." Bennett likewise advanced a physiological and a psychic explanation of these phenomena. Physiologically he thought that the nerve tubes of the white matter of the cerebral lobes became paralyzed through continued monotonous stimulation; while the action of others became exalted. Psychically, Bennett thought that certain ideas became prominent and controlled the individual outside his will and consciousness because that "portion of the brain with which they were associated had its action temporarily suspended, that is, the connection between the ganglion cells was broken, owing to the interrupted connection between the fibres of association."

Bernheim considers that "every one possesses a certain definite amount of nervous force or cerebral activity." In health and in our waking moments this nervous force "is concentrated in the higher nervous centres — the reasoning part of the brain — while in hypnosis it is concentrated in the lower centres — the imaginative or automatic part."

The latest theory that has been proposed for the solution of these problematic mental states is a more purely psychical one. "Instead of attempting to explain hypnotism by the arrested action of some of the brain centres which subserve normal life," this later theory frankly admits the existence of subconscious states and powers over which the individual normally possesses little or no control. Dr. Bramwell paraphrases Myers's idea thus: "The stream of consciousness in which we habitually live is not our only one. Possibly our habitual consciousness may be a mere selection from a multitude of thoughts and sensations. — some at least equally conscious with those we empirically know. No primacy is granted by this theory to the ordinary waking self, except that among potential selves it appears the fittest to meet the needs of common life. As a rule, the waking life is remembered in hypnosis, and the hypnotic life is forgotten in the waking state; this destroys any claim of the primary memory to be the

¹⁸ Brain, vol. xix, part iv.

sole memory. The self below the threshold of ordinary consciousness Myers terms the 'subliminal consciousness,' and the empirical self of common experience the 'supraliminal.' If this theory be true, then every individual possesses a spectral self vastly larger and more important than his normal empirical self. It may indeed dominate the man, and Stevenson's weird conception of Jekyll and Hyde contains more truth than fiction. However this may be, it is still quite likely that the physical and psychical elements both take part in the production of the hypnotic trance or subconscious states. That the latter play a much more prominent part in psycho-pathological conditions than was formerly supposed must be admitted. It is not inconceivable that in certain pathological states where there is functional activity of a very limited area the subliminal may entirely supplant the supraliminal self, although instances where such substitution occurs must be extremely rare.

From what has been said it is evident how close is the connection between consciousness and memory and their organic substratum in the neural pathways of the cortex. The least failure of the latter to act in conjunction with one another may lead to grave lapses in the continuity of consciousness and memory.

So much for theory. In conclusion a few words as to whether the clinical facts noted in the two cases are consistent with any of the theoretical views just considered.

In the first place, these two patients at, and previous to the time of the homicide were in a pathological mental condition. G. W. was not considered insane; but subsequent investigation disclosed the fact that he was subject to delusions and, not quite unlikely, to hallucinations. S. P., in addition to his advanced years, was mentally unbalanced — although, as is often the case, the extent of his alienation was not realized by his own family. He had marked delusions and hallucinations. Moreover, G. W. came from a distinctly neurotic family, many members of which had been insane. S. P. in his earlier life had been a hard drinker. There may have been hereditary neurotic history in his case, but this fact could not be ascertained. It is quite likely that the toxic effects of alcoholic indulgence in early life had to a certain extent led to the usual degenerative changes in the brain cells. Certainly his clinical history presented the symptoms ordinarily associated with chronic alcoholic insanity.

Both these individuals, then, presented the unstable brain which is the outgrowth of neurotic antecedents and toxic indulgence. The underlying mental existence was essentially morbid in either case. This is important. It seems very doubtful whether a fulminating psychosis, such as transitory frenzy, can ever occur in a healthy individual. It is quite likely that those cases that suddenly experience such psychic explosions are not mentally as well as they have been considered to be. Close investigation will disclose a pathological mental substratum which is itself the outgrowth of poorly organized or degenerative brain conditions.

Both cases were dominated by a single idea or group of ideas. G. W. dwelt constantly on the thought of his daughters being brought up to a life of prostitution. The fact of divorce only intensified this dread. Then in case divorce failed, the idea that he might be killed seized him, thus rendering it possible for his wife to be remarried, and without his protecting hand the degradation of his daughters would be complete.

In the case of S. P., the one dominant idea was fear for his life. Day and night he was haunted by this one idea, that his son would steal up behind him and slay him.

It is evident that in both cases there existed the most persistent state of monoideism. Presumably, an extremely limited circle of ideas was accompanied by functional associative activities in limited brain areas. Not that the entire brain did not perform the functions essential for ordinary life, but long-continued monoideism favored the functional exercise of certain brain paths more markedly than others. Consequently nervous activity sought these particular channels rather than others.

Both these cases lived in an unspeakable terror, both by day and night, that they were to be killed. In addition to this, in the case of G. W., the most horrible dread that a father could experience dominated and shadowed his daily existence like an awful cloud. He felt that his daughters, in whom his whole heart was bound up — even the littlest one scarcely out of her baby dresses — all were to be made common prostitutes in the course of time.

Both men had sought to arm themselves and prepare for the fatal moment which was likely to come upon them at any time. In the case of S. P. it was death; in that of G. W. it was not only his own personal death but the moral degradation of his daughters.

It is not difficult to see how certain neural brain paths may, in such conditions, be stimulated and rendered more instantly susceptible to the transmission of nerve force through them, rather than through other less used although contiguous channels. It is the old metaphor again of *short circuiting* of nerve currents. The easiest route is the one that will be used.

We can conceive, then, that in both these individuals the mental subsoil and the physical conditions were present and favorable for the exhibition of an explosive psychosis. All that was needed was the final spark — the metaphorical button with which to close the circuit, and uninhibited nature would accomplish the rest. In the case of G. W., the prolonged resistance of his wife at the railway station in her attempt to separate from him his little daughter, her persistence in securing the much-dreaded divorce, in an instant prepared the way for the free and immediate transmission of his entire nervous energy through routes which all unconsciously the unfortunate man had been preparing for many years. Pent-up fear, horror, anxiety all culminated in an act which was a mingled confused attempt at self-defence, anger, revenge, without restraint or reason. The act lacked purpose and intelligence. After all was over, the man stood dazed, trembling and exhausted, like one awakening from a terrible nightmare.

The explosion was, in one sense, analogous to the epileptic attack. Nervous force leaves its customary channels and flows with accumulated intensity through limited areas. *Normal consciousness* ceases because the usual neural pathways, through whose associative action this same normal consciousness is maintained, are, for the time being, cut out as it were — other tracts taking the entire force of the nerve current. *Amnesia* accompanied the explosive psychosis, both because of the suddenness, brevity and intensity of action in a very limited brain area, as well as the absence of that proper associative action in cortical brain paths so essential to normal consciousness and mem-

ory, and also because the subliminal self was supremely dominant, and, as is usually the case, no recollection is left of whatever happens during this condition. It would be interesting to know whether, within a few days of the explosion, hypnotism could have recalled to consciousness the recollection of what transpired by bringing the subliminal self again into the foreground.

In the case of S. P., the blow of the ball on the top of the head was the inciting agent. In an instant confused, aimless self-defence—the mere animal instinct of self-preservation—dominated the man; but so entirely motiveless was its demonstration that only purposeless homicidal violence was the result. For years the nervous mechanism, and particularly the subliminal self, had been led to anticipate this moment. Nervous energy was instantly withdrawn from the brain paths whose associative action is identified with normal consciousness, and transmitted with accumulated intensity through other tracts—the combined action of which eventuated in a motor display having for its object self-preservation and defence.

But the utter uselessness of the violence is worthy of notice and an evidence of the automatic and probably unconscious character of the act. In the case of S. P., the violent homicidal onslaught on the innocent and defenceless grandchildren whom he dearly loved, would seem to confirm the probable unconscious automaticity of the act. In G. W., the cyclonic character of the deed in the presence of many people certainly militates against premeditation, and the speechless, dazed condition of the man affords strong confirmatory evidence of its unconscious character. It is also significant that neither at the time nor after did either ever make any allusion to the homicide. The particular period of time seemed as though it were a blank. In none of the furious acts of the fulminating psychoses does the patient ever allude to what transpires at the time. This period is, to all appearances, as much a complete blank to the individual as are the acts of the epileptic when in the midst of his attack. Neither retains the faintest recollection of what has transpired.

In both cases there was rapid heart action, pallor, physical prostration. In the case of G. W., the patient said that everything turned dark—a struggle with a crowding upon him of men, was all that he could remember. This is very similar to the statement of those Malays who have recovered from an amok. I cannot help feeling that the two conditions are quite analogous.

I am well aware that the explanations herein advanced are rather visionary and insusceptible of actual proof. But that there may be a subliminal consciousness, that certain brain paths may be in active operation to the exclusion of certain other tracts that usually are, through their associative action, identified with the normal empirical consciousness—all this seems plausible and not inconsistent with what we already know of brain physiology and pathology.

THE SURGEON-GENERAL OF THE NAVY.—The President has appointed Dr. Newton C. Bates surgeon-general and chief of the bureau of medicine and surgery of the navy, to succeed Surgeon-General Tryon. Dr. Bates has been Mr. McKinley's family physician since the inauguration.

PHTHISIS AND CHILD-BEARING.¹

BY CHARLES W. TOWNSEND, M.D.

THE influence exerted by pulmonary tuberculosis on the course of pregnancy, labor and the puerperium is of considerable interest, owing to the prevalence of this disease and to its somewhat definite course under these conditions.

The following considerations are based on a study of twenty-four cases, all but two being patients of the Boston Lying-in Hospital:

Pregnancy.—During pregnancy the patient often seems better and the disease appears in abeyance, although in some advanced cases severe dyspnea and exhaustion may occur.

The appearance of improvement may have led to the erroneous view that pregnancy is a prophylactic or curative agent in tuberculosis. The subsequent course of the disease disproves this statement and also shows that the improvement is probably deceptive. It is reasonable to suppose that the diminished strength of the pregnant woman offers a favorable opportunity for the beginning of this disease in those who are predisposed.

All of the ten incipient cases went to full term; two of the four moderately severe cases were taken in labor at the eighth month, while, of the nine advanced cases of phthisis, three of them gave birth prematurely at the seventh and eighth month, and in one, labor was induced at that time owing to the feeble condition of the mother.

Labor.—The effect of the disease on the labor is interesting. In the incipient cases, the average duration of the first stage was sixteen hours, of the second stage, forty-three minutes, which is perhaps about the normal duration of labor, considering that one-half were primiparae. One labor was instrumental. In the four moderately severe cases, one a primipara, the average duration of the first stage was eleven hours, of the second stage twenty-three minutes. In the nine advanced cases, of which three were primiparae, the average length of the first stage was seven hours, of the second stage twenty-three minutes. In several of these cases coming under my observation the labor was markedly easy.

Instead, therefore, of the labor being prolonged and difficult, owing to the weakness of the patient in advanced cases of this disease, it is short and easy. The muscular power of the uterus seems to be good, while the resistance from the soft parts is slight.

Puerperium.—Nature seems to put forth a supreme effort to suppress the disease during pregnancy and to make the labor easy and short, but after the child is born the disease advances at a rapid rate. This is well shown in all the cases without exception by an examination of the temperature charts. In the incipient cases the temperature in all fluctuated from 98° to 100° or 101°, and in two, at the end of two weeks, the evening temperature rose to 103° and 104°. Weakness and cough were marked.

In the moderately severe cases of phthisis the temperature in all reached 100° and 101° and went to 103° in two cases at night. In the advanced cases a daily evening rise to 102° to 104° and even to 105° was noted.

Notwithstanding the absence of uterine symptoms it was often difficult to exclude sepsis as a cause of the

¹ Read before the Obstetrical Society of Boston, May 18, 1897.

temperature. In all doubtful cases, therefore, the uterus was explored and the result of this examination, together with the subsequent course of the disease, made the diagnosis certain. It is better to consider a case puerperal sepsis until it is proved to be tuberculosis.

All of the incipient and moderately severe cases passed from observation, but of the nine advanced cases, six were observed until their death, which took place in eight days in one case, in twelve days in one case, in one month in two cases, and in two months in the other two cases. In all of these the advances of the disease in the lung were very rapid.

One case remains to be considered. Here the patient was well up to the time of labor with the exception of a slight cough during the last three weeks of pregnancy. The labor was rather a long one, and on the fourth day the patient had a chill, followed by fever reaching 104° and 105° at night. The pain was referred to the chest and there were no uterine symptoms. The uterus was found to be normal, while signs of disease in the lungs were detected which rapidly increased. Tubercle bacilli appeared in the sputa. There was slight improvement during a stay of two weeks at the Massachusetts General Hospital, to which she was transferred from the Lying-in Hospital; her subsequent history is unknown.

This case is an example of tubercular disease of the lung originating in the weakened state of the woman during the latter part of pregnancy or early in the puerperium.

It is probable that some of the incipient cases began in pregnancy, although it was impossible in many cases to state the exact time of origin.

In this connection the observations of Flint on eighty-seven cases of phthisis in married women under forty years of age is of interest. Ten of these developed during pregnancy and twelve others within a few weeks or months after child-birth.

Pregnancy and the puerperium are dangerous periods, therefore, to those with a tendency to tuberculosis.

The Child.—The effect of the existence of tubercular disease in the mother on the condition of the child at birth is next to be considered. In the cases of incipient phthisis all the infants arrived at full term and all were discharged well at the end of two weeks, and one of these was known to be alive and well at the end of a year. The average birth-weight of these ten babies was six pounds and eleven ounces.

Of the moderately severe cases, two were a month premature, one of these giving birth to twins, both of whom died very soon, weighing only three pounds, and two pounds twelve ounces respectively. The other premature child and the two other children were discharged well in two weeks. The premature child weighed five and a half pounds, the others five and a half, and six pounds six ounces respectively.

In the class of advanced cases of phthisis, excluding the four premature cases, the average weight was six and a half pounds.

With the exception of one still-born child weighing two pounds, and one that died in three weeks, all the children in this class, including the premature, were discharged alive at the end of two weeks.

The average weight¹ of full-term children at the Boston Lying-in Hospital is seven pounds nine ounces

for males, and seven pounds five ounces for females, so that the weight of these babies of tuberculous mothers is only about a pound under the average.

A primipara who had been so long sick that she had not menstruated for thirteen months, or for four months before conception took place, who had cavities in the lungs and advanced tubercular laryngitis and who died eight days after a precipitate delivery, gave birth to an apparently healthy child weighing six pounds.

Another case, a multipara, the only out-patient of the hospital included in the list, had cavities in both lungs and laryngitis, and was so weak that she had been in bed for six months with resulting bed-sores. This patient went to full term and gave birth to an apparently healthy child weighing eight pounds and two ounces. The mother died twelve days later. It is certainly remarkable that these patients conceived, and that they gave birth at full term to such large living children. The subsequent history of these children is not known. It is possible that some of the children discharged apparently well may have been suffering from latent tuberculosis resulting from intra-uterine infection. Inherited tuberculosis in the sense of actual intra-uterine infection, the child being born tuberculous, has been proved to occur in so few instances that this accident must be extremely rare. In the absence of congenital tuberculosis, however, there probably exists in these children of tuberculous mothers an enfeebled constitution, rendering them a prey to this and other diseases. These children are further handicapped by the lack of mother's milk and by the constant exposure to tuberculous infection. For the sake of the child as well as to preserve the mother's strength, nursing is contraindicated. Nature generally enforces this rule by refusing to supply milk.

CONCLUSIONS.

- (1) Conception may take place even in advanced pulmonary tuberculosis.
- (2) The disease is generally held in abeyance during pregnancy, although it may advance or even originate at this time.
- (3) Labor is short and easy in proportion to the severity of the disease.
- (4) During the puerperium a rapid advance, leading in some cases to speedy death, occurs; or the disease may originate at this time. In either case the temperature chart suggests puerperal sepsis.
- (5) Premature labor is more common the more advanced the disease, although pregnancy often goes on to full term even in advanced cases.
- (6) The average weight of the full-term children and their general condition at birth is not markedly below that of children of healthy mothers, except in the rare instances of congenital tuberculosis.

A WELL-EQUIPPED MEDICAL SCHOOL.—Among the million or more medical colleges in this great country there is one with thirty-eight professors, twenty-three assistant professors and instructors, and fifty-one students. This gives one professor, assistant professor, or instructor to each student, with ten left over. It is suggested that a new medical journal be started, to give the idle ten something to do.—*Medical Record.*

Clinical Department.

A CASE OF EMANSIO MENSIIUM, OR ABSOLUTE AMENORRHEA, IN A MARRIED WOMAN TWENTY-SIX YEARS OLD.¹

BY W. L. BURRAGE, M.D.

THE following case seems to be of sufficient importance from its rarity to warrant being reported:

Mrs. E. H., Irish American, twenty-six years of age and married four years, consulted me for the first time April 2, 1897. She had never menstruated, and had had no menstrual molimen whatever.

She had lost her mother and one brother by phthisis; her father had rheumatism, and another brother had had rheumatic fever three times. Of three sisters, one (older than the patient) had four children, and of the two younger, one (aged twenty-two) had painful catamenia and weak spells, and the other had no uterine symptoms. The patient had varioloid when a baby, and scarlet fever at eighteen years of age. As a girl she had been healthy and of average strength. When seven years old she fell from the second story of a building to the cellar; but from the account of her sisters, received no more serious injuries than a shaking up and bruising. For five or six years Mrs. H. had suffered from periodical headaches coming on about a month apart, but with no definite regularity; and for the last year the headaches had been much more frequent, many times as often as once a week.

The pain was in the top of the head and coursed downward into the ears; and an attack would last, at first, three days every month, and for the last year a day or two nearly every week. The headaches were accompanied by nausea and great tenderness of the scalp, and were generally worse in the middle of the day and in warm weather. She had suffered off and on for four years with pains in the ankles, back and elbows. At times she walked lame because of the pain and swelling of the ankles. Had never had rheumatic fever. Digestion fairly good. Bowels regular. No periodic abdominal pains. No hemorrhages from the mucous surfaces of the body. Hot flashes of moderate severity had annoyed her of late, also sweating of the palms of the hands and axillæ and an evanescent eruption appearing on the arms and legs—papular reddened areas, circular in shape, about two centimetres in diameter and disappearing on pressure. No cough. No vesical symptoms. Coitus normal. Slight white vaginal discharge. No loss of weight. Urine, strongly acid, slightly high in color, 1.027, no albumin.

Physical examination showed a well-developed, fairly nourished woman of average height and weight; black hair and blue eyes and a rather muddy complexion. The hips were well proportioned; the breasts small, with diminutive nipples. Pubic hair and vulva normal in every respect. Vagina normal. Uterus small, symmetrical, retroverted and retroposited in the back of the pelvis, conforming in ante flexion to the curve of the sacrum, along which it lay and to which it was fixed by firm posterior adhesions. Behind the cervix on the left could be felt a knuckle of the left Fallopian tube, about the size of a slate pencil in diameter, thickened and slightly tender; and on the right side it was possible to make out only a small mass of indefinite outline that was sensitive on deep

pressure. The anterior lip of the cervix was somewhat flattened. The external os was patulous, and a probe entered the canal of the uterus a distance of 4.7 centimetres, and after traction on the cervix and using slight force, the point of the probe went by a tight constriction a farther distance of one centimetre, making the total uterine depth 5.7 centimetres, or two and a quarter inches.

The examination would show, then, evidences of an old inflammatory process about the tubes and ovaries, resulting presumably in atrophy of the ovaries, chronic inflammation of the tubes and stenosis of the uterine canal, besides anchoring the uterus in a pathological position in the pelvis.

It would seem that the initial inflammatory process must have taken place early in the patient's life in order so to crush the ovaries out of existence as to do away with menstruation altogether. Whether the varioloid, or the fall that she received, or tuberclosis, should stand in a causative relation to this process, we find it difficult to decide. It is certainly a very common occurrence to meet with an almost exactly similar uterine condition due to inflammation of the adnexa following septic abortion and labor where amenorrhea is not an attendant symptom.

The stenosis in the uterine canal being so near the fundus would point to an atrophied uterine body. It seems to me that this case is in a quite distinct class from those instances of amenorrhea from non-development or anomalous development of the uterus or vagina, for in the latter there is apt to be one or more attempts at menstruation, and an infantile uterus, small vagina, hypertrophy of the clitoris or other abnormality pointing to a primary lack of development.

VENTRO-FIXATION, WITH A REPORT OF TWO OPERATIONS ON THE SAME CASE.¹

BY GEO. W. KAN, M.D.,

Surgeon to Out-Patients, Free Hospital for Women.

THE patient, forty-eight years of age, was seen by me in consultation with Dr. Paine, of Brockton, February 28, 1896. Her previous history and symptoms are not essential for the purposes of this paper. Her uterus was found retroverted, adherent and sensitive.

The operation was March 10, 1896. After curetting, and repairing the lacerated cervix, I opened the abdomen, broke up the adhesions and brought the fundus forward. That there might afterward be some mobility of the uterus, I passed a suture of about No. 5 braided silk through the base of each round ligament. These two sutures were carried through the peritoneum and fascia on the corresponding sides of the incision and there fastened. I closed the abdomen with the full assurance that even should one ligature give way from any cause, the other would keep the uterus forward. Convalescence was uneventful, and the patient returned home relieved of the pressure symptoms caused by the retroverted uterus.

I saw her again in May, two and a half months after the operation, and found the uterus in good position.

In October of the same year she suffered severely from an attack of dysentery, which was epidemic in

¹ Read before the Obstetrical Society of Boston, May 18, 1897.

¹ Read, by invitation, before the Obstetrical Society of Boston, May 18, 1897.

Brockton at that time and the pressure symptoms returned in full force.

I saw her in the early part of this year and greatly to my chagrin found the uterus retroverted. I tried packing the vagina to bring the uterus forward again in the hope that a support could be worn, but I was not successful. The only course was to open the abdomen again, and this I did on March 18, 1897, almost exactly a year after the first operation, the incision being made a very little one side of the old one. On passing my fingers into the abdomen I felt a small cord attached to the abdominal peritoneum close to the line of incision, and extending through the coils of intestines down into the pelvis. Traction upon this cord brought the fundus into view, and showed its attachment to be at the base of the round ligament where the suture had been originally placed. A second cord was found on the other side. The left cord, about half a centimetre in diameter, was ten centimetres long; the right cord, not quite so thick, was eighteen centimetres long. The uterus could be lifted from its retroverted position by either of these cords. The silk sutures could not be found and apparently were absorbed.

This second time I fastened the uterus forward by a single suture of No. 10 braided silk passed first through the fascia and peritoneum of one side of the incision, then through the fundus of the uterus at the level of the round ligaments, taking in a half to three-quarters of an inch and carrying it about an eighth of an inch deep and then through the peritoneum and fascia of the opposite side. I have done a number of cases this way and have not had uterine bleeding of any amount. The stitch when tied brings the fundus to the abdominal wall and the edges of the incision together, and is a buried suture. I have had stitch sinuses in some cases but the uterus has remained in place after the stitch came away. I have tried twisted Chinese silk in my last case thinking it might be better sterilized than the heavy braided silk. I have had no stitch abscess from it.

The first ventro-fixation was by Koeberle in 1869, although Dr. Hunter mentions that about 1867-68 Dr. Sims suggested keeping the uterus forward after it had been replaced, by passing a silver wire through the abdominal wall and into the fundus. This idea was never carried out by him.

Koeberle removed two normal ovaries and fastened the stumps in the abdominal incision.

Tait, in February, 1880, reports two cases where, while closing the abdominal wound, he passed a stitch through the fundus of the uterus and fastened it to the abdominal wall.

Olshausen, one of the pioneers in this operation, made a report in September, 1886, at the Berlin Medical Congress. He wished it distinctly understood that he recommended limiting the operation to those patients whose age or condition makes pregnancy improbable. Only in rare unconquerable cases of adherent retroflexion and prolapsus does he believe the operation justifiable.

His method (Garrigues) is to carry a suture through the round ligament near the edge of the uterus, and the anterior layer of the broad ligament, then through the parietal peritoneum and part of the rectus muscle. Two more sutures are inserted below the first. Three similar sutures are placed on the other side, making six sutures in all.

Leopold fastens the uterus by three sutures through the fundus and abdominal wall and removes the sutures at the end of twelve to fifteen days.

Czerny passes two catgut sutures through fundus and peritoneum muscle and fascia but not integument.

Kelly, to whose writings upon this subject I am much indebted, reaches over the broad ligaments with his sutures and lifts the uterus by three sutures passed through the ovarian ligaments of each side, and through the abdominal parietal peritoneum. He says adhesions form at once but then soon stretch by the simple weight of the uterus, so that within two weeks the corpus uteri sinks to the level of the anterior vaginal wall.

Dorland, from a study of 179 cases of pregnancy following ventro-fixation, says in effect: "The object of the operation is to restore the uterus to its normal position and yet not fix it so firmly as to interfere with gestation and parturition."

In this Dorland goes beyond Olshausen, one of the originators of the operation, who limited its use to cases where pregnancy was improbable.

Dorland further says:

"If properly performed, hysteropexy should not result in a firm adhesion between the anterior uterine wall and the abdominal parietes, but in the formation of a partially elastic band which maintains the anterior position of the uterus, but does not destroy its mobility. To prevent this objectionable firm fixation some employ absorbable sutures and others remove the sutures within two weeks after operation. With fixation properly performed the uterus during gestation will gradually detach itself from the abdominal wall or the adhesions will stretch, and as the uterus undergoes involution it is restored to its original condition before the onset of the disease that rendered the fixation obligatory."

Dr. Penrose mentions having had an opportunity of examining the ligaments resulting from ventro-fixation in four cases. There were no adhesions present; there was a pliable ribbon from one and a half to three inches in length, about one-twelfth or one-eighth of an inch in thickness. In one case the ribbon broke as the uterus was drawn up through the abdominal incision, showing how yielding and fragile the structure is. He continues: "If all operators would endeavor merely to make a single, almost thread-like band, extending from the anterior abdominal wall to the top of the fundus uteri, little, if any, trouble would result from subsequent conception."

Peterson mentions finding these bands in a case where he performed a second celiotomy for intestinal obstruction from another cause.

In all the cases I have seen reported, the uterus has been found, when the abdomen was opened later, connected to the anterior abdominal wall by a band or bands of tissue, varying in length, up to those found in my case, and it is reasonable to suppose that a majority of cases of ventro-fixation have such bands, particularly those cases where the uterus is not firmly fixed. I have been taught and always considered that any band thus extending across the abdomen is a constant source of danger to the individual—the more bands the more danger. That these bands are not all so friable as that of Dr. Penrose is evident from the right one in my case having been stretched to eighteen centimetres, probably by intestinal force, while the left one was but ten centimetres, and yet each band in itself was

strong enough for me to draw the uterus out of Douglas's fossa to the opening in the abdomen. The case further shows that while a thread-like band may not complicate a future pregnancy, it does not always hold the uterus forward.

Dr. Grant's microscopic examination shows the bands to consist of "muscle fibres surrounded by connective tissue and numerous blood-vessels." These bands then would tend to grow firmer with age and so more dangerous. That no cases have been reported of intestinal obstruction due to this cause is no evidence that it has not occurred, nor does it warrant us by operation to add that element of danger to the patient.

In the view of ventro-fixation, as exemplified by this case, it seems to me to follow, that any method which holds the uterus forward by stitches on each side is faulty, in that it results in two bands at least, and that any method that allows of the formation of even a single band is undesirable. The class of cases in which ventro-fixation is indicated is in complicated retro-deviations; here *pregnancy* is always a doubtful matter; it should not be made a test for a successful operation, nor should it be made of paramount importance. Ventro-fixation is done to relieve the patient of symptoms depending upon malposition of the uterus; and this it does do decidedly. If it is found that succeeding pregnancies as a rule have an unfavorable course the rational procedure would seem to be, to always remove the ovaries in a ventro-fixation; and thus bring it in fact to Olshausen's limitation.

Medical Progress.

REPORT ON DERMATOLOGY.

BY JOHN T. BOWEN, M.D., BOSTON.

AIROL IN DERMATOLOGICAL PRACTICE.

As substitutes for iodoform, iodol, sozoidol, aristol, nosophen and dermatol have been introduced, and while all are in varying degree effective, none can compare with iodoform. Dermatol possesses marked astringent powers, but its antiseptic action is insufficient. To obviate this disadvantage iodine was added, and the preparation called aïrol obtained. It is a fine, greenish powder, insoluble in water. Haegler showed that its poisonous action is much less than that of iodoform. It was tried by Löblowitz¹ at Pick's clinic in Prague in a variety of skin affections, and the conclusion reached that healing was accomplished at least as quickly by its use as by iodoform or other antiseptic powders, although the difference was not marked. An especial advantage was the quickness with which it cleaned up suppurating surfaces; in other words, its antiseptic properties are marked. In most instances the ulcers treated presented a clean appearance by the third day. The astringent action was also marked, the secretion usually became less after the preparation had been used for twenty-four hours, and constantly diminished during the following days. This was seen by the color of the powder applied. Aïrol, when brought into contact with warm fluids, is changed into a yellowish-red powder by the breaking up of a part of its iodine. Hence as the amount of secretion diminishes a larger and larger part of the powder applied remains uncolored. Its power of

stimulating granulations in syphilitic ulcers is not great, and a disadvantage was found in a somewhat irritating effect on the mucous membranes in certain places. It was thought, however, that this only occurred when the epithelium had been macerated by a previous process and thus made more susceptible. The writer concludes that aïrol is an antiseptic that is usually quite sufficient; if a more energetic antiseptic action is desired, recourse must be had to iodoform; as an astringent, aïrol holds a high place; it has no odor and is very cheap.

THE BACTERIOLOGY OF SEBORRHEA AND ALOPECIA.

Sabouraud, whose late work on the tinea and on alopecia areata has received so much attention, endeavored to prove that seborrhea taken in its strict etymological sense, as a hypersecretion of the sebaceous glands, is caused by a specific pathogenic microbe.²

The oily seborrhea of the non-hairy parts offers two symptoms, an over-production of normal sebum, and an increase in the normal diameter of the sebaceous outlets which may be seen with the naked eye. On the hairy parts, particularly upon the scalp, a third symptom is added, namely, a diffuse falling of the hair, at first paroxysmal and which finally becomes persistent. Upon the scalp secondary infections may be grafted on a seborrhea, causing desquamative conditions, as pityriasis capitis, while on the face the different forms of acne may appear. The micro-bacillus of oily seborrhea is obtained by staining preparations of sebum by Gram's method, and consists of a small organism much like a coccus, easily stained by all aniline coloring matters. This bacillus is found in the upper third of the follicle, and its colonies are encysted in a mass of horny matter and sebum. This "cocoon" of cornified cells and sebum, containing in its centre the colonies of micro-bacilli, is the cylindrical plug that is expressed from the seborrheic skin. If these "cocons" increase greatly in size, a comedo is the result, which by a secondary infection may be converted into an acne pustule.

The formation of the seborrheic cocoon in the outlet of the hair follicle causes a progressive hypertrophy of the sebaceous gland. There is an invasion of leucocytes about the papilla of the hair, which gradually atrophies and dies. That this is due to a toxin from the bacillus may only be conjectured. Sabouraud energetically opposes the present classification which separates acne from the seborrheas from which it is derived. Unna and Hodara's acne bacillus, and the bacillus described by the former in oily seborrhea of the scalp, he considers identical with his micro-bacillus of seborrhea. Considerable difficulty was found in cultivating the bacillus of seborrhea; and as inoculation experiments proved failures, Sabouraud is forced to admit that he has not been able to clearly prove that it is the cause of seborrhea.

With regard to alopecia areata Sabouraud had previously studied its histology, which he now finds to be precisely similar to that of seborrhea. A differential diagnosis cannot be made by the microscope; and the bacillus which he had previously regarded as probably the cause of alopecia areata is the micro-bacillus of seborrhea. But his courage does not fail, and he reaches the rather startling conclusion that the etiology of alopecia areata and seborrhea is the same,

¹ Löblowitz: Archiv. f. Derm. u. Syph., 1897.

² La seborrhée grasse et la pelade, Annales de l'Institut Pasteur, February, 1897.

both being caused by the bacillus of seborrhea — acute alopecia areata is a local acute seborrhea, chronic extensive alopecia areata is a chronic generalized seborrhea.

In a later article³ Sabouraud seeks to extend his theory to the etiology of common, premature baldness. The sebaceous hypersecretion on the hairy as well as the non-hairy parts is followed by a glandular hypertrophy, and a progressive atrophy of the hair. Histologically, migratory cells, composed of lymphocytes and mastzellen are arranged in linear series around the cocoons at the mouths of the follicle, about the vessels near by, at the angle of the sebaceous gland, and about the base of the follicle and papilla. The papilla loses its functional activity, and the pigment is extravasated from the cells of the rete, so that the pigmentary cells of the hair lose their color. The medullary cells are not reproduced, and the diameter of the hair diminishes progressively. Finally, the complete death of the hair occurs. The vertex is the part which is especially affected by seborrhea and the resulting baldness. Not only is the seborrheic infection indispensable for the production of baldness, but this seborrheic infection remains intense and permanent when the baldness has been definitely established. Common baldness, therefore, is a definite, specific, microbic disease.

[However much admiration and respect we may have for the studies of Sabouraud, that have extended over several years, it seems evident that he has drawn conclusions as yet unwarranted by his facts. He has not been able to show that seborrhea and alopecia are caused by his micro-bacillus, and although his histological discoveries are interesting, it is too early to draw definite etiological conclusions from them.]

THE INFLUENCE OF LIGHT ON THE SKIN.⁴

Bowles, who has spent much time in investigating the effects of sunlight on the human body and especially the penetrating effects of reflected rays from snow and other surfaces, thinks that the Röntgen rays may be only modifications of ordinary light, as he has shown, he thinks, that reflected luminous or photo-chemical rays may penetrate the human skin into the deeper tissues in much the same way as do the x-rays. His previous studies have led him to the conclusion that sunburn is caused by the violet or ultra-violet rays, which are very strong at high altitudes, and that the deeper changes, such as are seen in "hydroa estivale," etc., are produced in the same way. He had predicted at the time of the publication of Röntgen's discovery that the x-rays would have the same effect on the tissues as the violet rays of light; and the various intense forms of dermatitis, with necrosis sometimes, which have been frequently reported, have made his prediction true. He believes, further, that rays that will produce such severe pathological effects on the skin, and which are known to pass through the vital organs must have a therapeutic or toxic action, according to the way they are employed and the amount. He would not be disposed, in the present state of our knowledge, to risk the effects of such a powerful agency on the cells of his own brain. Dr. Hammer had expressed the belief that fluorescent substances would prove the most effective in preventing sunburn, and had experimented by covering the skin with various substances, such as glycerine, vaseline, quinine in

various solutions, etc. Bowles's own experiments had accorded with those of Dr. Hammer, in that no transparent substance except quinine, which is strongly fluorescent, and therefore capable of absorbing the ultra-violet rays, was found to give satisfactory results.

In discussing Dr. Bowles's paper, Dr. Radcliffe Crocker said that with regard to freckles and other pigmentary changes, the influence of light was largely indirect, and influenced the skin through the medium of the nervous system, as pigmentary changes often appeared on parts of the body where light could have no influence. It had been shown that the Röntgen rays often produced a severe dermatitis, and their characteristic effect seemed to be a profound disturbance of the nutrition of the skin, and that the lesions did not heal so quickly as did those of all other forms of irritant dermatitis, but remained in the most indolent form, without any attempt at repair. He was inclined to agree with Dr. Bowles that there was a close relationship between the action of the sun's rays and that of the Röntgen rays. He had found by experiment that there were very strong chemical rays in an incandescent lamp, and that the effect on the eyes might be quite marked.

Dr. Walsh believed that the Röntgen rays were capable of damaging the deep as well as the superficial structures of the body. He instanced cases where demonstrators had been seized with attacks of gastro-enteritis, headache, vomiting, high temperature, etc. He thought that the traumatism might be due to the heat rays. He had seen two instances in which previously unsusceptible people had become susceptible suddenly, the only difference being that the kathodal end of the focus tube had been kept heated during the exposure.

Dr. Payne, the President, said that he had found that small-pox patients who were kept in a dark room to which only red light was admitted got well without any pitting of the skin, and, according to one observer, without any secondary fever. It was a curious fact that this was a revival of an old superstition, as in the Middle Ages physicians wrapped their patients in red cloths and put red hangings around the bed. With regard to the electric light he had had patients complain of its effect on the scalp. One had said that sitting under it for a long time caused a sensation of burning and tingling, and another that it had the effect of turning the hair gray. The latter statement should probably be taken with caution.

A NEW METHOD OF TREATING LUPUS ERYTHEMATOSUS.⁵

Schütz prefaces his communication with a comment on the well-known capriciousness of cases of lupus erythematosus. It is seldom that the same remedy acts equally well in two successive cases, and the present treatment consists in trying and alternating successive methods of treatment, all of which are often impotent. Oftentimes all active remedies must be abandoned and inflammatory appearances treated by simple soothing and protective applications, when an unexpected improvement may occur. He is convinced that every method of treatment that exceeds a certain individual degree of intensity or duration not only does no good but is actually harmful. Hence he does not advocate the use of strong caustics or operative interference.

³ Annales de Derm. et de Syph., March, 1897.

⁴ British Journal of Dermatology, July, 1897.

⁵ Archiv. f. Derm. u. Syph., 1897.

Five years previously Schütz had noticed that weak watery solutions of arsenic when painted on the skin, in a variety of cutaneous affections, produced an extraordinary degree of inflammation. A case of lupus erythematosus that had not been treated before, and that was not ulcerated, was converted into an eczema crustosum et madidans within twenty-four hours, by a single painting with Fowler's solution. Ten days later the inflammatory appearances had completely subsided, and the morbid process was strikingly improved. Further experiment proved that weaker solutions of arsenic had a still greater effect on lupus erythematosus. The less the inflammatory reaction the greater the improvement in the disease. Fowler's solution was diluted from four to six times and applied in nine cases. All these cases healed promptly, and no recurrence had been observed. His present method is to apply morning and evening the following mixture:

Sol. Fowleri	4.0
Aq. dest.	20.0-30.0
Chloroform	gtts. ii

This is allowed to dry on the skin, and no effect is noticed until the fourth or sixth day, when a slight swelling and redness is produced. The treatment is then discontinued, and a mild protective powder or paste is employed. When the swelling has subsided (in from four to eight days usually) the painting is resumed, and in six or eight weeks a marked improvement is noticed. As a rule, the lupus erythematosus is healed in this way in from ten to eleven weeks, without causing scars to remain.

He claims for this method its great assurance of success, although he admits that it may not be universal. In one case, that of a nervous woman, who had an extensive plaque on the head, headache was complained of after every fourth painting, which he was not inclined to attribute to hysteria.

According to Binz and Schütz, the action of arsenic is a continual reduction and oxidation, and this occurs wherever arsenic comes into contact with living protoplasm. The cells that are richest in protoplasm are the most affected, as those of the kidney and liver in poisoning, and the cells of malignant growths in injections. He seeks to explain the special action of arsenic on lupus erythematosus by the fact that we have in this affection inflammatory cell infiltrations along the blood-vessels, which are very superficial in their position, and therefore most easily accessible.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

REGULAR Meeting, May 18, 1897, the President, DR. FRANCIS H. DAVENPORT, in the chair.

DR. GEO. N. KAAH read, by invitation, on

VENTRO-FIXATION, WITH A REPORT OF TWO OPERATIONS ON THE SAME CASE.¹

DR. G. J. ENGELMANN said that as this operation had given a great deal of trouble in pregnancy it should only be resorted to after the menopause. In earlier cases Alexander's or some other operation should be employed.

DR. BEVERLEY McMONAGLE, of San Francisco,

¹ See Page 393 of the Journal.

said that in the operation of suspension of the uterus, intra-abdominal pressure bears on the uterus in such a way that it is kept in position.

Any operation which is going to interfere with a possible future pregnancy is a bad operation; and any operation will do this which puts a band between the uterus and abdominal wall that is not long enough to allow the uterus to sink down into normal position.

This operation is indicated in women who have passed the menopause, particularly in cases of procidentia.

Alexander's operation is indicated only where there is no disease of the uterus, ovaries, or Fallopian tubes, but where are two chances for hernia after the Alexander where the opening is pushed beyond the peritoneum, and only one in the operation for ventral fixation. The original operation is objectionable in that it makes in some cases a large painful scar as well as an abnormal antifixion.

DR. W. L. BURRAGE said that he thought favorably of ventral suspension in suitable cases, that is, in cases of retroversion with posterior adhesions, and where there is ovarian and tubal disease associated with retroversion, and in procidentia in old women.

Since receiving the notice of the reading of the paper under discussion he had had the curiosity to look over his records of operations, and had found that he had performed the operation forty-six times for one indication or another, and had made use of a large variety of methods, having used silk, silkworm-gut and catgut, and both temporary and permanent buried sutures, attaching the round ligaments to the parietal peritoneum, the ovarian ligaments and the fundus uteri, anterior and posterior faces, and to the same structure by stitches passing through the muscle, fascia and peritoneum, through all the structures of the abdominal wall or only through the peritoneum.

His present method was to suspend the fundus by attaching it to the parietal peritoneum alone by two or three sutures of No. 2 chromicized catgut that pass through the anterior and upper aspect deeply and through a wide margin of peritoneum, the surfaces of the peritoneum and fundus having been first scratched. He preferred to attach the anterior aspect of the fundus rather than the posterior, because in the published reports of dystocia following ventral fixation a large proportion of the cases had had incarceration of the anterior segment above the pubes, the fixation of the posterior fundus not permitting the uterus to rise to a sufficient height as pregnancy advanced.

In contrasting the Alexander operation with suspensio uteri, he much preferred the former where it could be done, namely, in cases devoid of adhesions and ovarian and tubal disease. Where the latter conditions obtained, it was still an open question how reliable and how generally applicable was an Alexander combined with a colpotomy. Certainly opening the abdomen from above made treating the ovaries and tubes, and at the same time suspending them with the uterus, a comparatively simple matter, whereas the Alexander did not always sufficiently raise these organs.

DR. M. STORER referred to a point in the technique of the operation of suspension of the uterus. In earlier cases he had found a lack of success due to the sutures tearing out, especially with a heavy uterus, so he now uses on either side of the uterus provisional silkworm-gut sutures, which are removed in ten days.

DR. C. W. TOWNSEND said he wished to protest against an operation that required the removal of the ovaries, as suggested by the writer in the last sentence of his paper, to prevent trouble from a possible pregnancy. Recent statistics, particularly those of Dr. Noble before the American Gynecological Society, showed the great danger to succeeding pregnancy from suspension or ventro-fixation of the uterus. The operation should therefore be strictly limited to those past the menopause or where the ovaries were removed for diseased conditions.

DR. M. H. RICHARDSON said that in cases of proclivencia he had tried every operation even to the extent of removing the uterus. All operations except this one of ventro-fixation are most unsatisfactory, but he has limited it to those past the menopause or in those not likely to become pregnant.

The Alexander operation is not successful in supporting a heavy uterus. The question of intestinal obstruction from these bands is of great interest, but the danger he believes to be extremely slight.

DR. F. H. DAVENPORT said there is no question but that ventral and vaginal fixation have led to bad results in pregnancy, so the tendency is now to limit the operation to those past the menopause. There has been a reaction in favor of the Alexander operation in uncomplicated cases. His practice in the ventro-fixation operation has been to pass the sutures through the anterior instead of the posterior part of the fundus, believing that this brings the uterus into the best position.

DR. EDW. REYNOLDS said that the operation of ventro-fixation was only adapted for cases of prolapse and for those past the child-bearing period. In a number of cases he had operated on causing suspension of the uterus, he had found at the end of a year or more that the uterus was in normal condition, freely movable, and he believed there was nothing left of the cord.

DR. CHARLES W. TOWNSEND read on

PHTHISIS AND CHILD-BEARING.¹

DR. J. B. SWIFT said he had had two cases of phthisis in pregnancy. The first case was far advanced, and died shortly after delivery. The second case originated in the first pregnancy following a pneumonia. She went to full term and gave birth to two children afterwards, but died suddenly soon after the last child. Both of these children were strong and healthy and were wet-nursed.

DR. A. WORCESTER said that these cases open up the question of the physician's duty towards the patient. In one of his cases where the woman had phthisis and became pregnant, he called consultation. It was agreed that the disease would be hastened by allowing the patient to go to full term, and that there was small chance of a healthy child, but the consultants did not think abortion was justifiable.

He objected strongly to the term "tendency to tuberculosis"; and he regretted that the profession were so shy about using tuberculin for diagnostic purposes, when it is shown to be of so great value in cows.

DR. BEVERLEY McMONAGLE referred to a patient with beginning phthisis where he had advised against pregnancy. The advice was not followed, and the patient boasted that far from being injured she was benefited by it. The disease ran a very rapid course,

however, after delivery, and she died in four months. The child is now fifteen months old, well and strong.

DR. C. W. TOWNSEND, in closing, said that his own cases, as well as those spoken of by others, showed very plainly the ill-effects of pregnancy on tuberculosis; but as the child was, in most cases, born in good condition, it might become a serious question whether it was right to consider abortion, as suggested by Dr. Worcester, whose statement, that there was but a small chance of a healthy child, was not borne out by these studies.

As to the term "tendency to tuberculosis," he believed that a child with feeble resisting powers had a tendency to tuberculosis as well as to other diseases.

The number of cases in which the child is actually born with the disease is very small. It is probable that in these cases the actual growth of the tubercles through the placenta is the mode by which the bacilli get into the fetal circulation.

Baumgarten believes that the large number of cases of tuberculous bone and joint disease of early life are in reality cases of congenital tuberculosis, where the bacilli have remained latent, these cases being analogous to late hereditary syphilis, the growing tissues of the child restraining or inhibiting the development of the germs.

DR. W. L. BURRAGE reported

A CASE OF EMANSIO MENSIIUM, OR ABSOLUTE AMENORRHEA IN A MARRIED WOMAN TWENTY-SIX YEARS OLD.²

DR. C. W. TOWNSEND said he had seen two or three similar cases at his out-patient clinic at the Massachusetts General Hospital. Two cases he recalled where the uterus was apparently normal or slightly diminished in size. In another case the woman was well formed, and the external genitals were apparently normal, but there was no trace of a vagina or uterus to be felt by the rectum.

DR. EDW. REYNOLDS reported

A CASE OF RENAL STONE,

and showed the specimen.

The patient complained of pain and tenderness under the right rib; and the case appeared to be one of right-sided pyelo-nephritis. By ureteral examination however, he found foul pus free from crystals of any sort coming from the *left* ureter, and a condition of mild pyelitis on the right side. Later, he cut down on the left kidney, and took out a stone as long as the last joint of the thumb.

Recent Literature.

Syngomyelia. By GUY HINSDALE, A.M., M.D. 8vo; pp. vii, 74, 29 illustrations. Philadelphia: International Medical Magazine Company. 1897.

To this essay, which is reprinted from the *International Medical Magazine*, was awarded the Alvarenga prize of the College of Physicians in Philadelphia in 1895. The essay embraces a careful synopsis of the literature, the report of two unpublished cases without autopsies, and a very complete bibliography. It is appalling to the student of neurology to consider that this bibliography of a comparatively rare affection con-

¹ See page 391 of the Journal.

² See page 393 of the Journal.

tains five hundred and fourteen titles, most of which have appeared within the past twenty years. A hundred and eighteen of the reported cases have been thoroughly analyzed in the study of the disease, although, unfortunately, the author has seen fit not to publish the synopsis of these cases originally presented with the essay. The analysis of the enormous mass of literature has been well done, and most of the doubtful points concerning the disease have been fully discussed, the evidence being so presented as to afford as far as possible the opportunity for a final decision. We take pleasure in commending this monograph as affording a valuable, indeed, the best summary of our present knowledge of the subject.

Clinical Lessons on Nervous Diseases. By S. WEIR MITCHELL, M.D., LL.D. Small 8vo; pp. 305, with two plates and 17 illustrations. Philadelphia and New York: Lea Brothers & Co. 1897.

It is curious and not unprofitable to compare the volume before us with the bulky and apparently exhaustive treatises on nervous diseases of Grasset and Ranzier or Gowers. Full as they are the present volume contains little in common with them, but, instead, it gleams after them the rare and unrecorded forms of nervous disease or remarkable conditions in the more familiar forms. Drawing thus upon the careful records from a rich experience, and presenting the facts with the well-known charm of Dr. Mitchell's style, the book is not only entertaining reading but it is a necessary appendix to the familiar treatises on nervous diseases. Some of the chapters, of course, deal with more familiar conditions, such as the treatment of sciatica, but even these have something original to present. Among the more interesting subjects considered are types of melancholia recurring at certain seasons of the year: disorders of sleep, including the relation of the præ-dormitum, or period preceding sleep, to insanity, nocturnal paralysis, sensory shocks and sleep-jerks, and respiratory failure; subjective false sensations of cold and wrong reference of sensations of pain; relief of erythromelalgia by section of the nerves; certain curious cases of spinal curvature associated with mental aberration; and some remarkable cases of hysterical contraction differing markedly from the forms of hysterical contraction described by the French. This, however, gives only an incomplete notion of the contents of the book, but it would require an elaborate analysis of each chapter to set forth all that the volume contains of value and suggestion to the neurologist, so that we must be content with commending it heartily to all who have any interest in the rarer forms of nervous disease.

Ophthalmic Operations as Practised on Animals' Eyes.

By CLARENCE A. VEASEY, A.M., M.D., Adjunct Professor of Diseases of the Eye, Philadelphia Polyclinic, etc. With 56 illustrations. Philadelphia: The Edwards & Dockert Co. 1896.

This is a small manual of 94 pages upon ophthalmic operations as performed upon animals' eyes for the purpose of teaching students the technique of the various operative procedures commonly employed upon the human eye. All the common operations are described for the removal of a foreign body from the cornea, Mules's operation, and resection of the optic nerve. No doubt it would make a good text-book for students to follow in practice operations, in connection with a course on operative ophthalmology.

Las Inflamaciones Pelvianas de la Mujer, y su Tratamiento mas inteligente segun las Clinicas. Report made to the Eleventh International Congress of Medicine, Department of Obstetrics and Gynecology. Celebrated at Rome from the 29th of March to the 5th of April, 1894. By DR. D. CELESTINE MARTIN de ARGENTA, Director of a Gynecological Clinic and the Professor of Gynecology at Salamanca. Madrid: *La Revista de Medicina y Cirujia Practicas.* 1894.

The author, after a very thorough and searching review of various abandoned pathological theories in gynecology, takes the very rational stand, that while it is of importance from a scientific standpoint for us to study the anatomical theories and sources of pelvic inflammation, yet these distinctions are from a clinical standpoint comparatively unimportant. He holds that there are too many refinements in our technical language, and that it would be better to place pretty much all of the inflammatory affections under the single title, "Peri-Metro-Salpingitis."

He then sets forth in detail a variety of arguments derived from analogy, in support of his belief that an inflammatory affection of any one of the sexual organs is necessarily accompanied by more or less of an inflammatory reaction in the whole generative system; from which he draws the inference that the treatment should be the same in all cases, excepting in so far as the degree of inflammation may warrant or not a surgical interference.

He believes that the introduction of ichthyol into gynecology has rendered it possible to cure almost all inflammatory affections of the generative organs without resorting to the knife, and describes in detail the manner in which he uses it. Internally, he gives half-grain pills of ichthyol, beginning with one pill three times a day, and increasing to a limit of 120 centigrammes. Locally, he resorts to thorough vaginal douches of corrosive sublimate and lysol solutions, followed by painting the vault with ten-per-cent. ichthyol and glycerine, and then by packing with iodoform gauze soaked in the same solution.

In severe cases he adds the use of ichthyol by rectal suppositories, and even abdominal injections of equal parts of ichthyol and lanolin. He believes that this treatment will lead to the resolution of all inflammatory lesions in which "suppuration has not yet been established or encysted." He is opposed to the operative treatment of any case without a previous resort to ichthyol. In rare cases he supplements this treatment by a ennetage, but he appears to practically eliminate the radical operations from his treatment of inflammatory affections, other than acute pelvic abscess and large pyo-salpinx.

A First Series of Fifty-four Consecutive Ovariectomies, with Fifty-three Recoveries. By A. C. BUTLER-SMYTHE F.R.C.S. Ed., F.R.C.P. Ed., Senior Surgeon to the Grosvenor Hospital for Women and Children; Senior Surgeon to Out-Patients, Samaritan Free Hospital for Women and Children. London: J. & A. Churchill. 1897.

Mr. Butler-Smythe has recorded his experience in ovariectomies. The histories of the cases are given in detail, and a table of operations is appended. The first part of the work is the most satisfactory, for it gives the results of the personal experience of the author. It is interesting to note that the author, on

page 5, states: "Ether, or gas and ether, are almost invariably used at my operations. Curiously enough, on the only two occasions where chloroform was given, I very nearly lost my patients from syncope. I have witnessed several deaths from this anesthetic, and frequently have seen cases where only the most energetic measures have been successful in averting a catastrophe. I regret to say that I never feel comfortable when giving chloroform, or when operating on a patient under its influence. In my opinion ether is a much safer anesthetic; and next to ether I prefer gas and ether, or the A. C. E. mixture."

This, as the opinion of an English surgeon, is worthy of note; for we are often led to believe that chloroform is used with perfect safety in the hands of English practitioners. We congratulate Mr. Butler-Smythe on his record, and trust that he will again contribute to the knowledge of this subject as his experience increases.

A Course in Practical Histology. By E. A. SCHÄFER. Second edition; 12mo; pp. xi, 298. Philadelphia: Lea Brothers & Co. 1897.

We are pleased to welcome a second edition of this excellent little manual, showing many improvements, through the author's careful revision. The volume is attractive in appearance, well printed and sufficiently illustrated. It is especially adapted to the needs of medical students, and to the wants of the practitioner who uses the microscope, as more and more practitioners do every year. Care has been taken to select the methods which, in the author's experience, can be completely relied upon; and no attempt has been made to give anything approaching a complete account of modern methods, the multiplicity of which is bewildering, and many of which have been devised only for a particular line of research. There is a introductory chapter on the microscope and other apparatus; then follow chapters on the tissues and organs, describing the best methods for each.

To judge the merit of the book, we have examined, first, the selection of the methods; second, the character of the directions given. The methods chosen are all good, and in many cases undoubtedly the best; but in a few cases we note omissions which are regrettable. Perhaps the most important is the absence of Zenker's Fluid, which, though very recently introduced, has already taken its place as one of the most valuable fixing solutions yet devised. We miss also Cox's modification of the Golgi method, and should like a fuller presentation of the uses of methylene-blue. As regards the clearness of the directions, there is nothing to be desired beyond what the book offers. American readers will regret that less space is not given to the inferior microtomes, and more to the superior types, commonly used with us.

This manual will be found very useful in connection with all practical work. Histological descriptions are, of course, not included in its scope.

THE PAY OF POLICE SURGEONS.—The police surgeons of Washington, D. C., have joined in a petition to the Commissioners, urging an increase in their gross estimate for the pay of the police surgeons of the District. Under the present rate the surgeons receive a monthly salary of forty-five dollars. Last year the calls and office consultations amounted to over fifteen thousand, and under the present salary they were paid for each consultation less than nine cents.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 14, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE SURGERY OF THE STOMACH.

EWALD,¹ of Berlin, read before the recent International Medical Congress a paper on this subject, which his large experience renders of great interest. The prognosis of operation upon the stomach has definitely improved, although there is still a marked difference between the results as reported by surgeons and physicians. He had had under observation in the past two and a half years 29 cases of gastro-enterostomy, 17 cases of resection, and 22 cases of gastrostomy. In most of the cases the condition dealt with was carcinoma, but there were three cases of benign stricture of the pylorus. In all but three cases the immediate operative result was perfect. The following were the final results: 26 gastro-enterostomies, with 16 deaths, or 62 per cent.; 13 resections, with 9 deaths, or 69.2 per cent.; and 22 gastrostomies, with 12 deaths, or 54 per cent. mortality. These results are more unfavorable than those reported by surgeons, especially those from Mikulicz's clinic. But the surgeon, says Ewald, often regards a survival of the operation as a cure.

The limitations of the indications for operation, which are very variable, cause the statistics to vary; for example, the exclusion of manifestly unfavorable cases, which improves the statistics. The principal reason for failure lies in conditions which are beyond the surgeon's control. Cases often present insurmountable difficulties.

For the prognosis the following factors are important: (1) the position of the tumor on the stomach wall and the extent of surface involved; (2) the extent of metastatic involvement of other organs; (3) the extent of cachexia and consequently diminished powers of absorption and assimilation after the operation. Before opening the abdomen one can form no idea of the position and relations of the tumor. The so-called early diagnosis of carcinoma by analysis of the gastric secretion has not proved of value. The increase in the lactic acid appears, as a rule, later than the time the tumor first becomes palpable. Without the palpa-

¹ Centralblatt für Innere Medizin, September 25, 1897.

ble tumor the diagnosis can only be extremely doubtful. We operate earlier at present than formerly, only because we make up our minds to operate, as a rule, sooner. The possibility of early operation depends entirely upon early recognition of the tumor. Gastrostomy is little more than a method of producing euthanasia. Cases of carcinoma of the esophagus should be supported as long as possible by feeding through esophageal tubes or per rectum, and gastrostomy attempted only when the body weight begins to diminish to the danger point.

In cases which apparently present favorable conditions for operation, the prognosis is always doubtful, and interference should be advised only with a full understanding of this fact. The prospects of a cure are hardly 25 per cent. and of improvement not more than 50 per cent.

For every possible reason, cases which seem favorable should be brought to operation at the earliest possible moment.

SUBCUTANEOUS INJECTIONS OF THE SALICYLATE OF MERCURY.

WOLTERS,¹ who has previously written on the subject of the local changes after intra-muscular injections of the salicylate of mercury, reports his observations made on a syphilitic patient who had died shortly after the injections had been made. Six injections had been made, the last one three months before death. The conditions for examination were favorable, as the foci were well isolated in the muscle tissue. The points of injections were evident on the cadaver, in the form of small, firm nodules, a circumstance that has been noted before. In some cases these nodules could be felt at the end of a year. The patient in question died of a polyneuritis; but whether this was produced by syphilis, mercury, or both together, could not be determined. Microscopical examination of the muscle excised at the point of injection showed the muscle bundles affected, a part of the fibres being preserved while many others were degenerated, and replaced by a tissue made up of large cavities and meshes. The larger and smaller cavities were mostly bounded by connective-tissue fibres, which contained many nuclei. In places, they took the form of canals, which followed the long axis of the muscle. "Mastzellen," pigment-bearing cells and free pigment were present, but no signs of fresh inflammation except about the vessels. There was a mild grade of endarteritis, both of the arteries and veins. It was evident in all places that the sarcolemma of the individual muscle fibres was in a state of proliferation, and was continuous with the tissue which bounded the vacuoles, therefore the canals and cavities are lined with sarcolemma, whose nuclei are in a state of active proliferation. Hence the result of the injection of salicylate of mercury is the mechanical and chemical destruction of a certain number of muscle fibres, from which are pro-

duced the cavities and canals, lined with sarcolemma. The sarcolemma proliferates, and later atrophies and produces scar tissue. No fibrin and no micro-organisms could be detected, and no mercury was apparent. Wolters considers that the latter fact, namely, that no mercury could be found at the site of the *dépôt* three months after the last injection, serves to disprove the objection often made, that there is danger of sudden absorption for a long time. He believes that the fluid injected is driven in between the muscle fibres either at the time of injection or shortly afterward, and forms the cavities and canals. He is in doubt as to what importance to attach to mechanical, and what to chemical factors, but inclines to the opinion that the latter are more active, and that there is a slow breaking up of the material injected. In the case of calomel there is a more acute and active splitting up at the point of injection.

In the same number of the *Archiv.*, Schulze writes of the danger of pulmonary embolism from the injection of salicylate of mercury. He reports the case of a man of thirty-two, perfectly well hitherto, who was treated at intervals of from five to eight days with injections of this drug suspended in liquid paraffine for syphilis. Immediately after the fourth injection, as the patient had just left the house, great giddiness and chills were experienced, followed by a long fit of coughing, by vomiting, and by sharp stinging pains in the left pulmonary region, so that he could scarcely breathe. He was assisted home, and had during the night and the following day great difficulty in breathing and severe coughing fits, although no physical signs were present. After a few days the symptoms disappeared and the injections were renewed.

Schulze thinks that this was undoubtedly an instance of pulmonary embolus, which was produced either by paraffine (in which the mercury was suspended) or by a particle of the drug itself. These symptoms, occurring as they did within five minutes after the injection, correspond completely with those described by Lesser and others in emboli from the injection of insoluble mercurial salts. In seven cases reported by Quincke, the symptoms did not appear so soon after the injection as in the case above reported, but this may be due to the fact that oil was used instead of liquid paraffine. Schulze regards the pulmonary symptoms as less likely to be caused by mercurial intoxication than by circulatory disturbances of an embolic nature. Möller has shown that embolic symptoms may be produced in animals solely by the injection of paraffine or gum arabic without the addition of a mercurial preparation, although it cannot be doubted that the addition of the mercury increases the danger, probably by increasing the size of the plugs carried into the veins. If the symptoms were solely those of an intoxication, other symptoms, such as stomatitis and enteritis, would be likely to be present, sooner or later. Blaschke's caution is approved of, namely, to be sure there is no blood on or in the canula after inserting the needle, and before making the injection.

¹ *Archiv. f. Derm. u. Syph.*, 1897.

If these precautions are taken, Schulze considers that the intra-muscular injection of insoluble preparations of mercury becomes as safe as any other mode of using mercury.

MEDICAL NOTES.

THE PRINCE OF WALES' HOSPITAL FUND now amounts to nearly £184,000.

THE PASTEUR INSTITUTE FOR INDIA.—The Maharaja of Patiala has presented the Indian government with a site for the Pasteur Institute to be established at Simla.

A CURATIVE SERUM FOR YELLOW FEVER.—The daily press publish telegraphic reports from Montevideo stating that Dr. Sanarelli announces that he has discovered a curative serum for yellow fever.

A MUSICAL FOREIGN BODY.—The *Medical Press and Circular* quotes from the *Revue de Laryngologie* the case of a girl of thirteen, who was throwing up in the air a toy trumpet for the playful purpose of catching it in her mouth, when suddenly it slipped into the windpipe, and afterwards down into the right bronchus. The result was that at each inspiration and expiration the trumpet gave out a note that could be heard fifteen yards away. The patient refused operation, and death occurred twenty-three days later.

YELLOW FEVER.—During the past week, the doubt cast by local physicians of Galveston, Tex., upon Dr. Guiteras's diagnosis of the fever in that city has been removed, and the disease has also appeared at Houston, Tex. Shot-gun quarantines have paralyzed commerce and common-sense between these cities and New Orleans, and traffic on the Houston and Texas Central and Southern Pacific railroads is almost at a stand-still. Reports from Mobile are more favorable, and in New Orleans there has been no marked change in the situation since last week.

OLINGER'S CONSUMPTION CURE.—The following extract from the *Denver Republican* shows the skill which a layman, even an undertaker, may display in drawing inferences on medical subjects from "his observations":

J. W. Olinger, a Fifteenth-Street undertaker, has discovered what he thinks is an undisputed fact. From his observations he believes that no person having a missing arm or leg ever contracts consumption; and he therefore suggests that amputation might be added to the many cures for the disease which are offered by humanitarians. He thinks the idea worthy the attention of the medical world. He further concludes that if amputation checks the circulation, amputation may not be required if the circulation is checked. He invites correspondence on the subject.

SMOKE.—At a debate on smoking among the members of the British Association, many speakers denounced and others advocated the practice. Professor Huxley said: "For forty years of my life tobacco has been a deadly poison to me. [Loud cheers from the antitobacconists.] In my youth, as a medical student I tried to smoke. In vain; at every fresh attempt my insidious foe stretched me prostrate on the floor. [Repeated cheers.] I entered the navy; again

I tried to smoke and again met with a defeat. I hated tobacco. I could almost have lent my support to any institution that had for its object the putting of tobacco smokers to death. [Vociferous applause.] A few years ago I was in Brittany with some friends. We went to an inn. They began to smoke. They looked very happy, and outside it was very wet and dismal. I thought I would try a cigar. [Murmurs.] I did so. [Great expectations.] I smoked that cigar; it was delicious! [Groans.] From that moment I was a changed man; and now I feel that smoking in moderation is a comfortable and laudable practice, and is productive of good. [Dismay and confusion of the antitobacconists. Roars of laughter from the smokers.] There is no more harm in a pipe than there is in a cup of tea. You may poison yourself by drinking too much green tea, and kill yourself by eating too many beefsteaks." [Total rout of the antitobacconists and complete triumph of the smokers.]—*Medical Record*.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, October 13, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 34, scarlet fever 41, measles 2, typhoid fever 26.

YELLOW FEVER ON A BOSTON-BOUND STEAMER.—The British steamer *Honiton* from Progreso, Mexico, for Boston, was detained off Vineyard Haven on October 8th by order of the Marine-Hospital Service, owing to the fact that she had lost three men from yellow fever on the voyage. She was brought from Vineyard Sound to Boston in charge of a pilot, and on arriving was detained at quarantine until October 11th, when having been thoroughly disinfected, she was allowed to proceed to her berth at Constitution Wharf. The crew were detained at quarantine a few days longer.

NEW YORK.

THE CRIMINAL AND THE STATE.—During the past week there was an exhibition of convicts' work and of various prison apparatus by the Prison Reform Association at its building in East 15th Street. One of the most curious collections in the exhibition was that of articles made by the inmates of the State Hospital for the Criminal Insane, at Matteawan, Dutchess County, of which Dr. H. E. Allison is superintendent, and in the same room with this was a series of plaster casts of noted criminals, affording opportunity for careful study.

During the three days' exhibition daily conferences were held in the rooms of the Association, and on the closing day, October 9th, the subject discussed was, "Criminal Types—Disease and Crime." The principal speaker was Dr. Austin Flint, who said, in part: "The criminal and crime, the treatment of the crime and of the criminal: these ideas come to me, as a physician, as of the first importance. It is not our prov-

ince to punish, much less to kill, unless the necessity is imperative. The worst thing we can do to a man is to kill him; the next worst is to imprison him. The best thing to do with a criminal is to cure him. It is with diffidence and yet with boldness that I allude to the practice of the judiciary, who are lawyers with no equipment for such work, attempting to decide the most intricate and delicate questions of psychology, a circumstance which often and inevitably leads to miscarriages of justice. It is often the fault of expert testimony, as it is given to-day, where the expert is an advocate and must make a good impression, that the court is misled. These questions of the mental condition of accused persons should be considered by a board of expert medical advisers, who shall determine what is the truth. There is a great deal of misapprehension of what is insanity. The matter would be simplified if one rule were followed. Insanity means a change, and every case must be measured by itself. What is a sign of insanity in one man is not in another — may in that other be natural to his condition or habits. Mere eccentricity is not insanity."

Dr. Flint said that while to-day, in his judgment, there is no such thing as a pathological anatomy of insanity, the world is standing on the threshold of the greatest discoveries. He predicted that the present study of the nerve cells of the brains of criminals would reach results that would make the best results hitherto attained seem almost trivial.

Secretary Round read a reply, strongly in the affirmative, by Dr. J. B. Ransom, physician at Clinton Prison, to the question: "Are you in favor of a Board of Medical Experts in court to determine matters within the province of the physician?" "A correct and efficient treatment must rest," he said, "as in all other departments of human affairs, upon proper classification as a primary and essential step to proper observation. Such classification, to be of value, must rest upon anthropological data. Inasmuch as anthropology is scientific and positively medical, the essential work of classification naturally falls within the physician's province, and can alone be performed by him. The first step, therefore, in classification, is the appointment to every criminal court of a competent physician or board of physicians to assist the court in determining expert questions relative to the criminal's physical and psychological condition at the time of the trial."

Dr. Allison, of the Matteawan State Hospital, then read a paper on "What Constitutes an Insane Criminal and What Status does he Occupy?" after which the Bertillon system was explained and discussed.

DR. EVANS'S PROPOSED CHARITIES. — Dr. Thomas W. Evans, the noted American dentist of Paris, who has treated the teeth of most of the royal families of Europe, sailed on the steamer *La Touraine* on October 9th, after a short visit to this country, the first that he has paid since 1856, when he went abroad to reside. Before starting he announced his intention to bequeath almost all his fortune, which is reported to be very large, to educational and benevolent insti-

tutions in America, and stated that he was already in communication with the heads of a number of universities in regard to the work and needs of their institutions. In particular, he has a special desire to establish a great dental school in Philadelphia, his native city, where deserving students may be enabled to acquire their profession at the least possible cost.

A NEW HOSPITAL FOR QUEENS COUNTY. — A new hospital, to be known as the Nassau Hospital, has been organized in Queens County, Long Island, and the association having the matter in charge has already secured temporary quarters for the institution at West Hempstead. It is proposed to erect a permanent hospital building at Mineola, and a successful entertainment in aid of the project was recently given at the Queens County Fair Grounds by the ladies of the towns in the vicinity.

DEATH OF DR. P. G. FRYE. — Dr. P. G. Frye, one of the oldest and best known physicians in Queens County, died at his residence at Oyster Bay on October 9th. He was eighty years of age. He was a native of Candia, N. H. He was much respected in the community, and at one time was President of the Queens County Medical Society.

DEATH OF DR. ARCHIBALD A. HIGGINS. — Dr. Archibald A. Higgins, a leading physician and former judge of Monmouth County, N. J., died at his residence at Manasquan, N. J., on October 9th, of Bright's disease. He was seventy years old. He was a member of the State Legislature in 1888 and 1889, and in 1893 was appointed by Governor Werts a lay judge of Monmouth County, in which capacity he served until legislated out of office by an act removing all lay judges in the State. He leaves a wife and one son, Dr. A. S. Higgins.

Miscellany.

BOSTON DISPENSARY.

THE statistics of this institution for the year ending September 30, 1897, are as follows:

The number of new patients treated at the Central Office is 28,865, classified as follows:

Medical Department. — Men, 3,058; women, 5,020; children, 4,775; total, 12,853.

Surgical Department. — Men, 1,466; women, 842; children, 663; total, 2,971.

Skin Department. — Men, 576; women, 627; children, 522; total, 1,725.

Department for Diseases of the Nervous System. — Men, 829; women, 1,235; children, 207; total, 2,271.

Department for Diseases of the Throat and Nose. — Men, 943; women, 863; children, 777; total, 2,583.

Department for Diseases of Women. — Women, 1,122.

Department for Diseases of the Eye. — Men, 354; women, 606; children, 389; total, 1,349.

Department for Diseases of the Ear. — Men, 230; women, 254; children, 284; total, 768.

Department for Diseases of the Genito-Urinary System. — Men, 2,261; women, 22; total, 2,283.

Department for Diseases of the Rectum and Anus. — Men, 113; women, 54; children, 1; total, 168.

Orthopedic Department. — Men, 121; women, 110; children, 42; total, 273.

Dental Department. — Men, 167; women, 159; children, 175; total, 499.

The number of visits made by patients old, and new, at the Central Office is 70,382, classified as follows:

Medical, 30,223; surgical, 40,159; total, 70,382.

The number of patients treated in the Districts is 15,352, including 448 cases of midwifery, classified as follows:

Men, 2,606; women; 6,020; children, 6,728; total, 15,352.

The results of treatment in the Districts are as follows:

Discharged, cured or relieved.	13,831
Removed to hospitals	1,271
Died	366
Remaining under treatment	90

15,458

Under treatment at last annual report 106

15,352

The number of visits made by the district physicians, 23,337

The number of patients treated at the Central Office 41,323

and in the districts

The number of cases midwifery attended during the 448

year

The number attended since July, 1856 8,497

Whole number of patients since October, 1796 1,378,845

Whole number of patients since July, 1856 1,259,682

Average daily attendance at the Central Office 230

Largest number present any one day, February 15th 383

Smallest number present any one day, January 28th 55

Number of recipes put up at the Central Office during 80,148

the year

Number of house recipes 67,879

Number of district recipes 12,269

Largest number put up in any one day, February 15th 423

Smallest number put up in any one day, January 28th 90

The list of medical officers for the ensuing year is as follows:

Surgeons. — Drs. Edward O. Otis, Frederic M. Briggs,

Edward A. Pease, Warren F. Gay.

Physicians. — Drs. Robert Disbrow, Thomas M. Rotch,

Harold Williams, Edward M. Buckingham, William F.

Temple, Henry Jackson, Robert W. Greenleaf, Samuel

Breck, George A. Sargent, Edward L. Twombly, William

E. Fay, William H. Prescott, Augustus S. Knight, Frederic

R. Tower, John W. Bartol, Edmund C. Stowell, Alfred A.

Wheeler, John N. Coolidge.

Department for Diseases of the Skin. — Drs. Francis B.

Greenough, Abner Post, James S. Howe.

Department for Diseases of the Nervous System. — Drs.

Frederic Coggeshall, William R. Woodbury.

Department for Diseases of the Throat and Nose. —

Drs. John W. Farlow, Frederic C. Cobb, William S.

Boardman, William E. Cheney. Assistant, Dr. Benjamin

Tenney.

Department for Diseases of Women. — Drs. John B.

Swift, George Haven, Malcolm Storer, Charles H. Hare.

Department for Diseases of the Eye. — Drs. Frank E.

Draper, William E. Baxter.

Department for Diseases of the Ear. — Drs. Wallace

Preble, Edgar M. Holmes. Assistants, Drs. Philip Ham-

mond, Charles S. Wright.

Department for Diseases of the Genito-Urinary System.

— Drs. Gardner W. Allen, Charles M. Whitney, Howard

A. Lothrop, C. Morton Smith.

Department for Diseases of the Rectum and Anus. —

Dr. Walter J. Otis. Assistants, Drs. Joseph C. Stedman,

John S. Phelps.

Obstetric Department. — Dr. Charles M. Green. As-

sistants, Drs. Edward Reynolds, Charles W. Townsend.

Orthopedic Department. — Drs. Calvin G. Page, Chas.

F. Painter.

Department for Mental Diseases. — Dr. Walter Chan-

ning.

Pathologist. — Dr. Edward M. Green.

Dentist. — Dr. A. H. Fisher.

District Physicians. — Drs. George M. Muttart, Fred

Drew, Carl A. Ewald, Arthur L. Chute, Frank A. Higgins,

William Cogswell, James S. Stone, George A. Harlow,

William P. Coates, Sidney A. Lord, Richard F. Chase,

Robert E. Edes.

Physician to Roxbury Central Office. — Dr. Henry F. Hewes.

Apothecary. — George Lachambre. Assistant, Everett C. Dodge. Dr. W. H. H. HASTINGS, Superintendent.

PERFORATION OF A GASTRIC ULCER INTO THE PERICARDIUM.

THIS accident is of such rare occurrence that the following comments of the *Lancet* upon a case reported in that journal for August 14th are of interest:

The probability of a gastric ulcer perforating the wall of the stomach depends chiefly on its situation. An ulcer on the anterior surface of the stomach will almost certainly lead to perforation if the ulcerative process continues; but should the ulcer be situated on the posterior wall adhesions form very readily, so that the stomach becomes adherent to the diaphragm or to the left lobe of the liver; but the diaphragm itself may become perforated by an extension of the ulceration, and then the ulcer may open into the left pleural cavity or into the pericardium. Perforation of the diaphragm by a gastric ulcer is decidedly a rare occurrence, and even when it does occur the pleura is much more frequently affected than the pericardium. Of 28 cases of perforation of the diaphragm by gastric ulcers collected by Ludwig Pick, only ten were cases in which the ulceration had perforated the pericardium. In the *Lancet* of August 14th is recorded a very interesting case which occurred in the practice of Mr. Collingwood Fenwick, in which a gastric ulcer had perforated the pericardium with an immediately fatal result, and yet no previous symptoms had occurred to point to the presence of the gastric ulcer. In four of the ten cases collected by Pick the two surfaces of the pericardium had become adherent before the ulceration had perforated, so that the ulcerative process involved the substance of the heart itself.

THE MISFORTUNES OF A MEDICAL MAN.

ALL the French daily papers have recently given much space to the discussion of the case of Dr. La Porte; and in *Le Matin*, a Paris daily, on September 21st, under the scare heads, "Obstetrical Butchery," "Delivery by Mallet Blows," etc., appeared an account of the case of the young doctor living in the Quartier de Charonne, whose experience furnishes food for reflection.

This young physician had been in practice since 1893. He had moved to the quarter only fifteen days before, and was one of those called upon to make night calls on the poor, for which they are inadequately paid by the police department. The compensation for a night visit to an obstetric case is the munificent sum of ten francs, or twenty francs if the physician personally delivers the woman.

It seems, according to the report, that Dr. La Porte answered a police call to a woman in the quarter who had been in labor for two days under the care of a midwife, who had unsuccessfully attempted to deliver her by operative means. On the doctor's arrival he found the woman much exhausted, administered chloroform, and after spending three-quarters of an hour in the attempt to apply the forceps, found that the lock would not work, and he could not get them on. He had no instruments for craniotomy; but considering that immediate delivery was imperative, he told the husband he must sacrifice the child's life to save the mother, called for the tool box, and attempted to perforate the

head, first with an upholsterer's needle, and then with a hammer and chisel. The husband, however, could no longer endure the sight of this "revolting butchery," and snatched the mallet and chisel from the doctor's hand; the woman came out of chloroform, and the doctor, as the husband would no longer allow him to proceed with the delivery, left the house, after protesting against the husband's interference with his operation.

Another physician was called, who had the woman sent to a lying-in hospital, where she died in about an hour after giving birth to a mutilated infant. An autopsy performed on the body of the woman showed that the bladder and peritoneum had been perforated by the upholsterer's needle.

The unfortunate physician had been locked up on the charge of incompetence and malpractice: the story of the operation is told, with the usual embellishments, by the daily press; the doctor is accused of carelessness and culpable neglect in not having suitable instruments at hand, and of butchery, in attempting to deliver the woman with a chisel and mallet. He, very reasonably, it seems, protests that instruments for craniotomy are not ordinarily carried by physicians even to instrumental deliveries, and that there was no time to send for them. The midwife loyally stands by the doctor, and says that he did not act with the brutality with which he is accused.

A physician, Dr. Erzbischoff, who is well and favorably known in the district, and has been in practice there for thirty years, according to the reporter, remarks: "My feeling is that my young friend acted unwisely in attempting so dangerous and difficult an operation without more experience, and the possession of suitable instruments, etc.," and then proceeds to display to the reporters the imposing array of brilliantly shining instruments in their cases "which no one ought to attempt obstetric cases without, etc." In the following issue of the paper the doctor comes out with the statement that he had been misrepresented, and that what he said was, that if Dr. La Porte had had a longer experience as emergency physician to the police department he would probably not have undertaken the operation of craniotomy single-handed, but would have sent the woman to a hospital.

Such incidents as the foregoing portray in startling colors the difficulties which beset the young practitioner among an ignorant class in the community. If he is a man of courage and confidence in his own skill, he is apt to undertake operative work in cases where another man, with less confidence, would send the patient to a hospital. Any surgeon doing emergency practice in the dwellings of the ignorant poor exposes himself, in case the patient dies, to the danger of getting into Dr. La Porte's situation. Such practice requires hard common-sense, avoiding timidity on the one hand and rashness on the other. The want of this quality, as well as the want of proper instruments, seems to have undone this doctor and this patient. The precaution of having the patient's family absent from the room, which physicians who practise among the well-to-do are able to take, is unfortunately impracticable in the dwellings of the poor, where, in cases of emergency, one is obliged to depend upon them for assistance.

As to Dr. Erzbischoff, he apparently talked too much.

To those who think the path of the poor young

physician is strewn with flowers, the following comparison by a writer in the *Canadian Medical Review* of the choice of a career between the Klondike and a medical education is worthy of consideration:

It may be asked by many a young man just now whether he should go to the Yukon or to a medical college. So far as the *Review* is concerned, it would not seriously advise either course to glory, a fortune or the grave. If, however, some youths, ambitious for fortune or fame, are determined to go to one or the other of the above places, then really the balance of argument lies in favor of the Yukon. By going to the latter place one will make something soon or lose everything in the attempt. Of two forms of death, it would appear that being frozen is full as easy as the gradual one of starving to death by the slow academical method of attending a medical college. What though fifty per cent. should meet with death by freezing or speedy starvation in the search for gold in the Klondike, would not the results in the end be better than that ninety per cent. should meet with disappointment in the search for gold after spending many years in the study of medicine? If either form of fever is to attack young men, we think the prognosis is decidedly in favor of the Yukon type, as compared with the medical-school type. The latter is a very lingering disease.

It is well in starting on either career to take plenty of provisions, and prepare for an arctic winter—in the case of the medical student of many years' duration.

Correspondence.

THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

October 1, 1897.

MR. EDITOR:—Whatever the results, practical and otherwise, of the International Medical Congress recently held at Moscow, it is as yet too premature to judge; one thing, however, is certain: it has uncovered a *terra incognita* before the eyes of the scientific world; it has shown that the "Barbarians of the North" have progressed in medical and allied sciences by gigantic strides to a position not very far from that occupied by the other European nations. The Russian has proved himself to be not only an apt pupil, but also a careful and conscientious independent investigator. The difficulties of the Russian tongue have served as a great obstacle in the way of introducing the world of science to the vast accumulation of scientific labor and original research, of which the Congressists caught but a glimpse from the papers read by the Russians and from visiting the medical institutions of Moscow and other cities. There are fields of labor—as that of the so-called "zemstvo" physicians—which are peculiarly adapted to the conditions of life in Russia, and which cannot possibly be comprehended, and therefore appreciated by a foreigner: in these an enormous amount of work is done by thousands of quiet, unobtrusive practitioners, especially in the line of public hygiene, of which there is a truly lamentable lack in a great many parts of the empire, and which, in view of the ignorance of the population, it takes more than ordinary courage to establish.

As far as can be judged, the Congress—with the exception of some inevitable occurrences of an unpleasant nature—turned out to be a success. The great number of physicians, among whom shone not a few stars of the first magnitude, the abundance of papers presented, and the importance of the subjects discussed,—all prove conclusively that the medical world has accepted the invitation of Russia to the Congress most willingly; although it is not to be denied, that curiosity to see the "Russian bear" in his lair prompted not a few in responding to the call. What they saw in Moscow (or to be more explicit, what was shown to them of Moscow) was certainly a pleasant disappointment. I understand that the Executive Committee of the Convention, notwithstanding a great

many obstacles in their way (of which the foreigners need not necessarily be cognizant) have discharged their duties to the satisfaction of all, and it was certainly due partly to their efforts that the great numbers of foreigners left Moscow with a greater, so to say, scientific baggage, than they brought with them. Add to this the proverbial Russian hospitality, that seemed to even excel itself on the occasion, the unique features of Moscow — with its Kremlin, on one side, reminding one of some Asiatic city; and its hospitals, libraries, scientific collections, its great university, on the other hand — and you will readily perceive that the impression left on the minds of the foreigners by Russia and its representative scientists will be lasting and favorable. With the impressionable nature of the Russian and his almost fanatical love for science (a trait of character readily noticed by the keen Virchow) no one can foretell what a powerful impetus in the direction of scientific investigation the Congress has given to Russian science. At the same time nothing could so elevate the standing of Russian culture beyond the confines of the empire.

Not by any means the last party to profit by the "feast of science" is the Russian government. Constantly holding in check the embryonic public opinion of the land, the Russian government has always striven to create for itself a favorable public opinion in Europe (the utility of such a policy does not concern us here), sometimes at the expense of a great deal of energy, as by subsidizing certain parts of the press in Europe, keeping a whole system of spies, etc. It requires no fertile mind to comprehend, that having taken a most active participation in the preparations for the Congress, and having extended unbounded hospitality to the foreigners (for if the Russian government *does* do things, it does not do them by halves), the Czar himself taking an almost direct interest in the proceedings, the government has won over to its side hundreds of intelligent staunch supporters, who will carry with them pleasant remembrances into all the corners of the habitable globe. This is by no means a matter of small importance. We all remember the flutter of excitement and the adverse criticism toward the Russian liberals, created by the sensational reports of Rev. DeWitt Talmage's visit to St. Petersburg and his interview with the Czar, who not only allowed him to enter his most august presence, but actually permitted him to taste of his cuisine and to pat his children!

As if to strengthen the political *mésalliance* between France and Russia, the next Medical Congress has chosen Paris as its place of meeting. But strange to say, as compared with the Germans, both quantitatively and qualitatively, the French were insufficiently represented in Moscow. Besides, the methodical Germans had their Committees all prearranged long before the opening of the Congress, while the Frenchmen were rather slow in doing so; hence, very probably, the great difference in the respective representations.

Of the many famous men present no two attracted as much attention as the great master Rudolf Virchow and the founder of the modern school of criminology, Cesare Lombroso. The venerable old teacher, who counted among those present many a gray-haired pupil (Virchow is seventy-six years old) of his, called out quite a pathetic protest, when he intimated in his opening speech that this may be the last medical congress he is able to attend. Of his several addresses that in the Section of General Pathology on the "Rôle of the Vessels and of the Parenchyma in Inflammation," seems to be the most notable one.

A deputation from the women physicians of Russia thanked him for his efforts in behalf of the medical education of women; in 1893, when the women were not admitted to the University, Professor Virchow was the first to open his lecture-rooms and laboratories to them. In reply he said, that the woman brings into her scientific work an idealism and the purity of her soul. He also expressed his delight at the opening of the medical school for women in St. Petersburg.

Prof. C. Lombroso, whose appearance was hailed with delight, as he has quite a number of appreciative admirers

among the Russians, delivered, among others, a notable address on the "Latest Requisitions of Psychiatry." An unassuming servant to medicine, psychiatry has invaded so many departments of knowledge, that no other branch of science can be compared to it. She has given a new and more perfect classification of hysteria, she has elucidated many points regarding epilepsy, revealed the etiology of pellagra, alcoholism, ergotism, discovered a whole series of degenerative processes in cretinism, goitre and myxedema, at the same time giving us means to either foresee or to cure these degenerations. She has explained the nature of the phenomena of epidemic fanaticism. She has succeeded in proving that a great many of the so-called criminals are in reality sick men who, instead of being punished, must be subjected to medical treatment. Guided by clinical experimentalism, the progressive alienists came to the conclusion, that they must study rather the patient than the disease, that they must find in the patient's physical and functional disturbances as much as they look for in psychical alterations. Fortified by their first successful efforts the alienists continued in the same direction, hoping to discover certain characteristic traits, that would aid them in distinguishing the sane from the insane. Without as yet finding these, they nevertheless established a new method of investigation in the domains of psychiatry and crime. They have concluded, that against the *a priori* investigation of the crime, we must put the direct analytical examination of the criminal himself, and of the conditions of life surrounding him; guided by this idea, our system of punishment must be such as to act rather less severely, but the law must strive to set aside the conditions creating the criminal.

In the domain of psychology she has first of all shown the parallelism between the phenomena of ideation, so far beyond and above our control, on the one hand, and the phenomena of perception, so easily verified, on the other hand. We all know the perseverance of very strong and very prolonged impressions, that are left even after the subject causing them, has disappeared. This law of perseverance is found to be uppermost in the mental sphere of the insane; thus one patient who became insane because of fright caused by an explosion of powder, continued to imagine himself in the midst of flames. Such and a great many other facts assist us in comprehending the mechanism of thinking. In the cortical strata of the brain in which thought is formed there takes place a movement, analogous to that said by the physiologists to take place in the end-fibres of the sensory nerves.

Psychiatry thus leads us further than pathological anatomy. Thought presents in reality the diminished image of the subject, an image called out by sensation. But while in the condition of waking, thanks to the predominance of brighter perceptions, this image is so pale, that we are unable to determine its nature. Only when these perception phenomena disappear, as in sleep, in the hallucination of the monomaniac or of the hypnotized subject, does the idea become what it was, that is, an image. But it is while studying hypnotism and hysteria, that the secrets of psychical phenomena are revealed to us, because knowledge of these mental conditions enables us to understand the secret with the aid of experimental investigation. Facts prove that thought is connected with the law of molecular motion of the cortical brain matter.

Professor Lombroso paid a flying visit to Count Leo Tolstoi, whom he considers one of the greatest minds of the century, and does not at all agree with Dr. M. Nordau in classing him among the great degenerates. Unfortunately, one of the count's sons was just then passing through a severe typhoid, and the doctor's stay had to be shortened.

In the Section of Gynecology and Obstetrics, Professor Sneguireff, of Moscow, delivered the Chairman's Address, in the course of which he pointed to the picture of Raphael's Sistine Madonna as a perfect type of healthy and beautiful womanhood, for which science and art must strive. "Take care that the cradle of humanity is healthy, because health is beauty, beauty is truth, and truth is happiness. The peace of the future and happiness on earth consist in the

knowledge of preserving one's strength, given by nature, and in developing the harmony founded on mutual love and respect. Not only may the woman enjoy the rights that we enjoy, but she must have more rights and less duties."

By the number of important papers under discussion the Section on Hygiene was one of the most interesting. Prof. V. Vaughan, of Ann Arbor, Mich., read a very able paper on the examination of drinking-water, and Professor Novy, of the same University, on the necessity of instruction in the elementary schools in the measures for combating infectious diseases. To organize the work of public hygiene, Dr. Burgerstein recommends in his paper the systematic spreading of popularly written treatises on the subject by the aid of some official method; the instruction in hygiene by competent teachers in all the schools of the land; the establishment of chairs to institutes of hygiene in connection with every medical school so as to prepare a sufficient number of specialists in public hygiene; a special sum to be designated by the central government for the purpose of instructing the people in hygiene.

Among other addresses in the same Section was one on "Alcoholism in its Relation to Public Hygiene." Dr. Grigorjeff, of St. Petersburg, brought forward some interesting statistics concerning the State monopoly of the sale of alcohol in Russia; in general it has tended to diminish the evil. Dr. Yarosheffsky, of Samara, discussed the special hospitals for alcoholics. He and Dr. Korovin have among other things called the attention of those present to the fact, that among those battling against the great evil in the civilized communities, the physicians are not to be found; although they could do much more than the various prohibition societies, whose utility is after all a matter of fiction rather than of reality; alcoholism is to be considered as a sort of an epidemic disease and treated accordingly.

A most brilliant address was delivered by the famous neuro-pathologist, Krafft-Ebbing, on the "Etiology of Progressive Paralysis." It was a skilful analysis of the condition of modern civilized life, done by the hand of a master. He pointed out that the modern man has paid dearly for the great progress in trade, manufacture, agriculture and for the innumerable inventions. The intensity of the modern life is still more enhanced by the political activity, the great diversity of opinions, the struggle for existence, not only among individuals, but among classes and nations; the nervous system is thus in a condition of never-ceasing excitation, increased by the abuse of the various nervines, as tobacco, tea, coffee, alcohol. The physical degeneration of the great masses of people segregated in the large manufacturing centres is the true reflection of their miserable conditions of life, and appears as rachitis, scrofulosis, tuberculosis, etc. The female is not surrounded by any more favorable circumstances. Such conditions form certainly a very fertile soil for the development of various nervous disorders, among which progressive paralysis occupies a pre-eminent place. The ever-spreading curse of syphilis is probably the most important etiological factor in the causation of the disease; he would, however, not commit himself to considering syphilis as a *sine qua non* in the etiology of progressive paralysis. If he were to state the etiological factors of the disease he would say: "civilization and syphilization."

Another hardly less interesting and important address was that by Prof. I. Metchnikoff on "The Plague." The interest in the paper was heightened by the fact, that the author applied the comparatively new method of serum-therapy in the treatment of the disease, which up to lately was considered only as a subject of historical interest and not of medical importance; but its recent appearance in India and in Hong Kong has attracted the attention of the scientific world. Recent investigation of the plague has enabled us to diagnose the disease early and to check its spread in time, and so perfected has the method become that even a student is now able to diagnose a case of the plague.

Very truly yours,

A. ROVINSKY, M.D.

METEOROLOGICAL RECORD

For the week ending October 2d, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Amesbury	10,920	—	—	—	—	—	—	—	

Deaths reported 2,834; under five years of age 1,003; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 431, consumption 337, acute lung diseases 219, diarrheal diseases 222, diphtheria and croup 103, typhoid fever 51, whooping-cough 51, malarial fever 15, scarlet fever 12, cerebro-spinal meningitis 7, measles 5, erysipelas 2.

From whooping-cough Chicago 10, Baltimore 7, St. Louis 6, Brooklyn and Boston 5 each, New York and Philadelphia 4 each, Cincinnati 3, Cleveland, Charleston and Cambridge 2 each, New Bedford 1. From scarlet fever New York 5, Philadelphia, Brooklyn and Lawrence 2 each, Baltimore 1. From malarial fever St. Louis 6, Baltimore, Nashville, Charleston and Fall River 2 each. From cerebro-spinal meningitis Lynn 2, New York, St. Louis, Worcester, Malden and Everett 1 each. From

measles New York, Chicago, Baltimore, Providence and Cambridge 1 each. From erysipelas Chicago and Baltimore 1 each. In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending September 25th, the death-rate was 17.1. Deaths reported 3,600, diarrhoea 237, diphtheria 75, fever 57, measles 54, whooping-cough 51, scarlet fever 43.

The death-rates ranged from 22.5 in Liverpool to 10.4 in Swansea; Birmingham 20.0, Bradford 16.7, Cardiff 14.7, Gateshead 16.0, Huddersfield 14.9, Hull 18.5, Leeds 15.7, Leicester 16.9, London 15.7, Manchester 22.3, Newcastle-on-Tyne 18.7, Norwich 14.7, Nottingham 16.3, Portsmouth 14.0, Salford 20.1, Sheffield 22.4, Sunderland 21.3.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 2, 1897, TO OCTOBER 8, 1897.

CAPTAIN RICHARD W. JOHNSON, assistant surgeon, ordered to proceed from Fort Logan, Col., to Fort Douglas, Utah, and report for temporary duty.

FIRST-LIEUT. LEIGH A. FULLER, assistant surgeon, is relieved from duty at Fort Meade, S. D., and ordered to Fort Assiniboine, Mon.

FIRST-LIEUT. EDWARD L. MUNSON, assistant surgeon, is relieved from duty at Fort Assiniboine, Mon., and ordered to Fort Adams, R. I.

CAPTAIN GEORGE MCCREERY, assistant surgeon, is relieved from temporary duty at the U. S. Soldiers' Home, Washington, D. C., and ordered to Fort Myer, Va.

CAPTAIN EDGAR A. MEARNES, assistant surgeon, is relieved from duty at Fort Myer, Va., and ordered to Fort Clark, Tex.

CAPTAIN JAMES D. GLENNAN, assistant surgeon, is relieved from duty at Fort Clark, Tex., and ordered to Fort Myer, Va.

The order assigning CAPTAIN NORTON STRONG, assistant surgeon, to duty at Fort Myer, Va., is revoked.

CAPTAIN ROBERT R. BALL, assistant surgeon, died October 5, 1897, at Washington, D. C.

Leave of absence for one month is granted FIRST-LIEUT. THOMAS J. KIRKPATRICK, JR., assistant surgeon, Fort Douglas, Utah.

PROMOTION.

CAPTAIN JUNIUS L. POWELL, assistant surgeon, to be surgeon, with the rank of Major, October 1, 1897, *vice* BROWN, retired.

RETIREMENT.

MAJOR PAUL R. BROWN, surgeon, having been found by an Army Retiring Board incapacitated for active service by reason of disability incident to the service, by direction of the President, retired from active service this date, October 1, 1897.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The first regular meeting of the year 1897-98 will be held at the Medical Library, 19 Boylston Place, on Monday evening, October 18th, at 8 o'clock.

The leading subject of the evening will be "Physical Training in the Public Schools." Dr. Walter Channing will make a report on behalf of a committee appointed to investigate the question. Other speakers will be Drs. C. J. Blake, E. H. Bradford, W. M. Conant, E. M. Hartwell, and, by invitation, Dr. S. H. Calderwood.

Dr. H. F. Vickery will report a case of "Transposition of the Viscera."

Dr. Thomas Dwight, by invitation, will demonstrate a new original model of the Abdominal Viscera.

JAMES G. MUMFORD, M.D., *Secretary*, 197 Beacon St.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology and Hygiene will hold its first meeting of the year at the Medical Library, 19 Boylston Place, Wednesday evening, October 20th, at 8 p. m.

Short communications by Drs. A. A. Taft, Mark W. Richardson, R. C. Cabot.

Paper by Dr. C. N. Barney: "Cerebral Syphilis; with Report of a Case of Chronic Meningo-Encephalitis, Secondary to Syphilis." Discussion opened by Dr. J. J. Putnam.

Meeting of November 17th. Drs. W. W. Gannett and Wm. T. Councilman: "Yellow Fever."

E. W. TAYLOR, M.D., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Obstetrics and Diseases of Women will meet at 19 Boylston Place, Wednesday, October 27, 1897, at 8 p. m.

Papers: Dr. Storer, "Vulvo-Vaginitis in Children." Dr. Burrage, "Some Results of the Postural Method of Draining the Peritoneal Cavity after Abdominal Operations."

F. W. JOHNSON, M.D., *Chairman*.
C. H. HARE, M.D., *Secretary*.

RECENT DEATH.

ROBERT B. MORISON, M.D., of Baltimore, died suddenly September 30th. He had for some time been afflicted with Bright's disease. He was born in Baltimore and was a son of the late Dr. N. H. Morison, for many years provost of the Peabody Institute, and a nephew of the late Rev. J. H. Morison, D.D., of Milton. Dr. Morison entered Harvard with the class of 1873, but left college at the end of his sophomore year. He graduated from the medical department of the University of Maryland in 1874, and afterwards studied for several years in the hospitals of Europe. He was at one time in the faculty of the University of Maryland, and subsequently dermatologist at Johns Hopkins Hospital. He had a wide reputation as a dermatologist, and was formerly a frequent contributor to medical journals. He had been president of the American Dermatological Association.

BOOKS AND PAMPHLETS RECEIVED.

Recurrent Gall-Stones. Angioma of Spleen. Excision of Cecum. By John Homans, M.D., Boston, Mass.

E. Merck, Darmstadt, Verzeichniss Sämmtlicher Präparate, Drogen, und Mineralien mit Erläuterungen. 1897.

The Diagnosis and Treatment of Chronic Gastric Catarrh. By Frank H. Murdoch, M.D., Pittsburgh, Pa. Reprint. 1897.

Remarks on Laminectomy, with Report of a Case done Sixteen Months after Fracture. By Oscar J. Mayer, M.D., San Francisco. Reprint. 1897.

Report of the Commissioner of Education for the year 1895-96. Volume 1, containing Part 1. Washington: Government Printing Office. 1897.

Fiftieth Anniversary of the Hartford Medical Society, founded September 15, 1846. Proceedings at the Celebration October 26, 1896, at Hartford, Conn.

The Treatment of Malaria. Clinical Lecture delivered at the Philadelphia Hospital. By Judson Daland, M.D. (Univ. of Penna.), Philadelphia. Reprint. 1897.

A Criticism of Modified Milk and of Modern Dairy Methods. Some Personal Observations upon the Effects of Changes of Climate upon Men and Animals. By Richard Cole Newton, M.D., Montclair, N. J. Reprints. 1897.

Epiphora, or Watery Eye; Lacrymal Abscess; Necrosis of the Bony Walls of the Lacrymal Canal; Implantation of a Glass Ball for the Support of an Artificial Eye; Grattage for the Radical Cure of Granular Lids. By L. Webster Fox, M.D., Philadelphia. Reprint. 1897.

Appendicitis and Its Surgical Treatment, with a Report of Seventy-five Operated Cases. By Herman Myer, M.D. (Copenhagen), Professor of Operative and Clinical Surgery in Niagara University, and Surgeon to the Sisters of Charity Hospital in Buffalo, N. Y. Philadelphia: J. B. Lippincott Co. 1897.

The Origin of Disease, Especially of Disease Resulting from Intrinsic as Opposed to Extrinsic Causes, with Chapters on Diagnosis, Prognosis and Treatment. By Arthur V. Meigs, M.D., Physician to the Pennsylvania Hospital. With 137 original illustrations. Philadelphia: J. B. Lippincott Co. 1897.

Essentials of Obstetrics. By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Pediatrics in the Long Island College Hospital, and Obstetrician to the Hospital, assisted by Harold F. Jewett, M.D. Illustrated by 80 wood-cuts and three colored plates. New York and Philadelphia: Lea Brothers & Co. 1897.

Tuberculosis of the Genito-Urinary Organs, Male and Female. By N. Senn, M.D., Ph.D., LL.D., Professor of Practice of Surgery and Clinical Surgery, Rush Medical College; Attending Surgeon to the Presbyterian Hospital; Surgeon-in-Chief, St. Joseph's Hospital, Chicago. Illustrated. Philadelphia: W. B. Saunders. 1897.

The Diseases of Women, a Hand-Book for Students and Practitioners. By J. Bland Sutton, F.R.C.S., Eng., Surgeon to the Chelsea Hospital for Women; Assistant Surgeon, Middlesex Hospital, London, and Arthur E. Giles, M.D., B.Sc., London, F.R.C.S., Edin., Assistant Surgeon, Chelsea Hospital for Women, London. With 115 illustrations. Philadelphia: W. B. Saunders. 1897.

A Manual of Legal Medicine for the Use of Practitioners and Students of Medicine and Law. By Justin Herold, A.M., M.D., formerly Coroner's Physician of New York City and County; late House Physician and Surgeon of St. Vincent's Hospital, New York City; Member of the New York County Medical Association, Medico-Legal Society, etc. Philadelphia: J. B. Lippincott & Co. 1897.

The Normal and Pathological Circulation in the Central Nervous System (Myelo-Encephalon). Original Studies by William Browning, Ph.D., M.D., Attending Neurologist to the Kings County Hospital; Lecturer on Normal Neurology at the Long Island College Hospital, etc.; Member of the Society of American Anatomists, the American Neurological Association, etc. Philadelphia: J. B. Lippincott Co. 1897.

Original Articles.

A NEW METHOD FOR THE REMOVAL OF DISEASED PROCESSES IN THE NECK POSTERIOR TO THE STERNO-MASTOID MUSCLE.¹

BY FRANK HARTLEY, M.D., NEW YORK,
Surgeon to the New York Hospital.

GENTLEMEN:—I wish to thank you for the honor you confer upon me to-night, and to ask your indulgence if I am repeating to you what you may already know better than I.

For some years I have been especially interested in the surgery of the neck, and have paid particular attention to the manner in which operators have progressed when attacking extensive disease in this region. I must admit that I see but few who seem to be so thoroughly conversant with the anatomy that they proceed with ease and confidence in the detailed work of an operation, give themselves a sufficient field in which to do their work and avoid hugging too closely the diseased tissue. It is the exception to find one who willingly operates in the distinctly uninvolved region, dissecting out the important structures first and finally removing the growth itself, unless that region be some such a one as the submaxillary triangle.

I wish, therefore, to call to your notice a method of operation designed for a more thorough removal of processes in the neck involving the space occupied by the sheath of the carotid, and in front, beneath and behind the sterno-mastoid muscle.

For those who operate continually upon the neck many cases of glandular enlargement will necessarily come under their observation; and although the minor degrees of these enlargements are easily removed by the normal and adopted incisions in front or behind the sterno-mastoid, or curved incisions exposing the submaxillary and superior carotid triangles, or a combination of these incisions, nevertheless, a sufficient number remains where no combination of these incisions will expose a sufficient area for a careful and precise dissection of the vessels and nerves from the infiltrating and adherent mass without extensive scars.

The complete exposure of the important parts of the neck at the beginning of the operation renders it safer and consumes less time than when one is adding incisions to expose certain extensions of the disease. Especially is this the case where the growths are extensive, as in carcinoma and sarcoma, where we wish to operate wide of the disease and must have the field to work in. For this work usually the operator is content with making his incision in front of the sterno-mastoid, only to find if the case be an extensive one, that he must either do unsatisfactory work, and not divide the sterno-mastoid muscle, or he adds another incision behind this muscle and works beneath it. In other incisions he makes the H incision with division of his sterno-mastoid muscle, and leaves parts of three scars to be subsequently seen.

It has been my custom in general to use for the sub-

maxillary triangle the incision adopted by Kocher for the tongue. A straight incision on the anterior border of the sterno-mastoid for the superior and inferior carotid triangle, and an incision behind the sterno-mastoid for the posterior superior triangle; but in all these cases the disease is not extensive and does not involve extensively the region beneath the sterno-mastoid muscle.

When the disease involves, however, the space beneath this muscle, encroaching upon the superior and inferior carotid triangles, as well as the posterior triangles of the neck, my method of procedure has been as follows:

The incision begins generally just below the mastoid process, a variable distance, depending upon the upper level of the growth, and passes in front of the sterno-mastoid muscle to its middle, when the direction is slightly altered to end at a point one inch above the sterno-clavicular articulation, thence laterally with a rounded angle above the clavicle and across the poste-

rior triangle of the neck a sufficient length to expose this region and to allow a line drawn from the two extremities of the incision to pass behind the posterior margin of the mass.

We now incise to or through the platysma muscle and strip back the skin to beyond the growth, so that when the flap is held up a straight line will be made from the two extremities of the incision along the attached border of the flap. The external jugular is tied above and below. Anteriorly, we expose the posterior belly of the digastric muscle and the omohyoid muscles as landmarks. This brings us into direct relation with the common facial vein, facial artery, the lingual, occipital, posterior auricular and superior thyroid arteries and veins and the hypoglossal and descendens noni nerves in the upper triangle, while in the lower triangle beneath these muscles are the jugular (internal) vein and the common carotid artery. At this level on the posterior border of the sterno-mastoid muscle we expose and divide, if necessary, the superficial branches of the cervical plexus (the ascending, transverse and descending), and recognize distinctly the spinal accessory nerve above and the omo-

¹ Read before the Surgical Section of the Suffolk District Medical Society, April 30, 1897.

hyoid muscles below, placing us in relation with the anatomy of the posterior triangles.

We now divide the sterno-mastoid about its middle from without inward, so as to recognize the posterior layer of the fascia forming its sheath. In some instances the muscle is already so stretched by tubercular glands and so easily retracted that this division is not necessary. Yet I think in such cases, unless the disease involves an extensive area both anterior and posterior to the sterno-mastoid as well as behind it, the anterior or posterior straight incision would rather have been indicated. In case the sterno-mastoid is divided and its posterior sheath recognized, it is lifted above with the retractor and the spinal accessory nerve is seen entering and traversing the muscle. The descendens noni, the jugular vein and carotid artery, and possibly pneumogastric nerve and sympathetic nerve should now be recognized and seen. The lower half of the sterno-mastoid is now reflected below in the same manner. This gives us at this level the omohyoid muscle and immediately internal to it the sterno-hyoid muscle, the common carotid artery, internal jugular vein, and the communications with the anterior and external jugular vein, behind which is the pneumogastric nerve, the sympathetic nerve and the vertebral artery. We also see here the upper branches of the brachial plexus and the communication with the lower cervical nerves.

It is here and at this level that one extirpating either glands or a new growth must dissect with the greatest care, both in order not to injure the communicating branches of the cervical with the brachial nerves or the muscular branches of the brachial plexus. Yet it can be accomplished in all cases where operation should be attempted, and in those cases where the nerves must be sacrificed the chances for prolongation of the life of the patient must counterbalance the paralysis following. This avoidance of injury to the nerves can generally be done by remembering to keep well above the scalenus anticus, medius, levator anguli scapulae and to dissect closely to the mass here until the nerves are seen. In the upper portion of the field the danger consists in extensive cutting as one approaches the spinal accessory just as it passes beneath the jugular vein, as we wish to preserve its connection with the three cervicals before its entrance into the sterno-mastoid as well as the first two cervical with the hypoglossal, and the three upper cervical with the sympathetic ganglion (superior). The third and fourth nerves, together with the second and third, give us the sensory nerves, and these may, if necessary, be divided without concern. The muscular branches are situated so close to the muscles which they supply, and so close to the scaleni over which they pass, that injury to them is not feared with reasonable care.

The brachial plexus proper, that is, the cords forming it, is so well protected by the scalenus anticus and medius that there is little fear of injury to it.

Yet here in a close dissection we wish to avoid the rhomboid branch from the fifth passing through the scalenus medius and beneath the levator anguli scapulae, the subclavian from the fifth and sixth passing over the plexus and subclavian artery to the subclavius muscle, the supra-scapular from the fifth and sixth branches passing in the posterior superior triangle beneath the trapezius and to the supra-spinatus muscle.

The branches from the third, fourth and fifth to the phrenic are not so liable to injury since the dissection

here is oftener easier because of the later infection of glands; and if the process were malignant it would contraindicate operative interference. In this portion of the wound is also seen the subclavian artery, internal jugular vein with subclavian veins, the thyroid axis, the vertebral artery, and once I have recognized the thoracic duct. There is little danger of injuring these structures provided one protects them with blunt retractors and has a perfect and clean view of his field of work.

The anatomical points to remember may seem to many surgeons somewhat extensive, and so to endanger too much the life or future usefulness of the patient; but I will answer to this that those who do their work in narrow and ill-lighted fields in dangerous regions are themselves more liable to two dangers, either the incomplete removal of the tumor or the injury of just the particular tissues mentioned. In such a region and for the class of cases for which it is to be used it should be the idea of the surgeon to locate his growth first in reference to its relation to the surrounding important parts and remove them from the tumor, rather than the tumor from them, for the best healing of large wounds is found when the tissue left is perfectly uninvolved by the disease, and the imperfect nutrition of the tissue from the pressure, etc., of the growth has been relieved.

The conditions in which this method of procedure may be used are (1) tubercular lymphadenomata occupying the space uncovered by the flap, especially those cases of more or less rapidly growing lymphadenoma which have been known as Hodgkin's disease, pseudo-leukemia, etc., many of which are now found to be tubercular and which when thoroughly extirpated do not recur, as I can testify in a number of cases; (2) chronic hyperplastic lymphadenomata; (3) malignant glands or tumors when deemed removable; (4) thyroidal accessory growths; and (5) the deep branchogenic tumors of this region. All of these cases may be considered as applicable to this incision when they occupy the region mentioned, that is, behind the sterno-mastoid as well as in front, and which are not fully exposed without a division or retraction of the muscle.

Such cases are in my mind more rapidly performed when the muscle is divided at first — and certainly more carefully, safely and completely. I am most certainly in favor of the complete removal of the disease, whatever it may be; and the imperfect results I have seen have always been those in which such a removal was not or could not be carried out. In no instance where such a removal was accomplished has there been a directly local return. Even in tubercular abscess in this region its enucleation in this manner has always been followed by the kindest healing. An incision such as this carries out the surgical demand to make an incision in the skin sufficient to allow a careful and safe procedure in the depth. The extent of the remaining scar is of no importance, provided that it fall in the normal direction and is attended with an exact suture. Langer's investigation in the normal-skin cleavage has shown that in certain directions in the body incisions will vary much in gaping of the wounds, so that in one direction the borders of the wound will of themselves remain apposed, in other directions will gape more or less extensively. More important is also (and these two points often correspond) the direction of the vessels and nerves.

The incision mentioned here follows as near as possible the natural cleavage of the skin and the direction of the muscles and nerves, and gives in all cases a finer scar than an incision at right angles or oblique to this one.

I therefore believe that in this incision we attain the greatest field of exposure with the earliest possible chance for removal of stitches and the most thorough removal of the disease. As I have previously mentioned, I have been interested in this region for some years and have been watching carefully the manner of procedure in other operators, and I determined some time ago to work on this line in order to have a decided method of procedure in all cases, no matter what the extent, provided the location was the same. It is

wound healing was not so good nor the scarring so slight. I have, therefore, given them up during the last year and have used only the above-described incision.

The only drainage necessary is through a small incision made in the attached border of the flap on the anterior border of the trapezius muscle at the junction of the lower one-third and upper two-thirds of this same attached border.

In conclusion, I wish to state that I believe we have for all regions of the neck incisions which show but little disfigurement except in the region here mentioned. For the submaxillary, the submental, the subhyoid, the superior and inferior carotid triangles and the subclavian triangles, the most approved incisions

so often observable that an operator starts with an incision behind or before the muscle and making a poor enucleation, either gives it up or adds a curved or transverse cut over the sterno-mastoid with division of the muscles in order to give a field, but only after a great expenditure of time and often much bleeding. One readily sees that nothing was foreseen, and that the operation was devised as he went along. Instead of the two or three scars, is it not better to have one observable scar in the neck and a complete exposure from the beginning.

The cases operated upon in this manner have included two extensive sarcomata and thirteen large tubercular lymphadenomata, in one of which cases over forty glands were removed, and in another thirty-eight glands. Both of these latter cases resembled in general appearance the glands of pseudo-leucocythemia. One branchiogenic tumor was comparatively easily removed on account of ready exposure of the field. At the Roosevelt Hospital the assistants themselves did five cases. Although the incisions formerly used by me—the U, the S, the H and the T—have been attended with the same dissection in the depth, and have given the same complete exposure, yet the

are arranged in accordance with embryological development and the natural cleavage of the skin. In the region here considered, where the disease is extensive and requires a thorough exposure, incisions have largely disregarded these rules.

By the employment of this method it has been my endeavor to obtain (1) a complete exposure of the field in which one is to operate; (2) a scar which is seen along the anterior border of the sterno mastoid muscle in a natural depression in the neck and not very noticeable in the ordinary dress if primary union in the wound has occurred; (3) a complete exposure of the important tissues of the neck, permitting one to remove completely the diseased tissue and at the same time to command with ease and certainty the danger of hemorrhage and nerve section in any part of the neck, from the mastoid process to the clavicle; (4) an incision parallel to the arteries and nerves and in the line of the cleavage of the skin securing an early primary union, a slight scar and a diminished danger of infection of the wound from such early and complete union; (5) a rapid union of the wound, permitting an early dismissal from the hospital. The usual time necessary for observation is one to fourteen days.

THE DIAGNOSIS OF SOME COMMON INJURIES IN THE SHOULDER REGION.¹

BY AGNES C. VIETOR, M.D., BOSTON, MASS.,

Acting House-Surgeon, New England Hospital, Boston; Late Instructor in Physical Diagnosis and Surgery, Woman's Medical College of the New York Infirmary, etc.

IN the winter of 1895-96, through the kindness of Dr. Van Arsdaile, I studied, at the Good Samaritan Dispensary, 23 patients who complained of pain and impairment of motion in the shoulder region. Of these, 14 traced their disability to an injury.²

In examining the patients, it is necessary to say, I followed the same system in each case. First, the patient was inspected passively as to attitude, position and relations. Then, the bones and joints of the entire shoulder girdle, the upper vertebrae, the sternum and the ribs were examined, to exclude the grosser lesions of fracture, dislocation, etc. Next, an examination of the softer tissues was made; and, finally, measurements of the arms, forearms and hands were taken. This topographical survey having shown the anatomical relations present, the physiology of the various structures was next investigated. That of the bones, joints, muscles and nerves was studied by having the patient execute all the voluntary movements possible, and supplementing this inquiry by putting him or her through the circle of possible passive motions. Sensations of touch, temperature and pain were inquired into. The examination was then continued by the use of the faradic and galvanic currents for testing the finer responses and the nutrition of the nerves and muscles in the shoulder region and of the arm;³ where any suspicion attached to the forearm, the examination included that and the hand. Finally, the boundaries of the heart, lungs, liver and spleen were outlined, and the heart and lungs auscultated. I regret that the limitations of a crowded clinic prevented me from learning that most important thing—the condition of the kidneys.

The reports which follow contain simply the departures from the normal which were noted.

CASE I. A woman, forty-six years old, housewife. Eleven weeks ago she tripped over a rug, and fell forward, bruising her right arm and knee. No swelling resulted, but a small ecchymosis formed in the region of the internal condyle of the humerus. At first she could not raise her arm from the side, but gradually the use of it returned, except that she cannot yet button her skirts at the back of the waist line. She complains also of spontaneous pain in the neck, along the anterior border of the trapezius; in the shoulder, just where the acromion overhangs the joint; and vaguely over the scapula; also, down the whole of the arm and forearm, but most marked in the deltoid region, in the bend of the elbow and at the wrist; and in the fingers when she rubs the forearm. Sometimes, there are vague feelings of "needles" in the same regions. At night, the arm feels heavy; all movements are made with more difficulty and the pain is greater.

Physical Examination.—Comparison made with the left side. Right deltoid region appears smaller;

there is a depression behind the head of the humerus, below the acromion process (posterior deltoid region); prominence of the vertebral border of the scapula, a furrow forming beneath it as the arm is abducted or when the shoulders are moved forwards. Pressure high up in the axilla, in the region of the brachial plexus, gives the same pain in the shoulder as that of which she complains. Tenderness on pressure on the outside of the arm, just below the acromion, also in front of the acromion. Right deltoid and biceps are both one centimetre smaller than left.

Voluntary Movements.—Abduction is slow, feeble and apprehensive; at about 60° it causes pain in the neck, arm and down the radial side of the dorsum of the forearm; when the arm becomes horizontal, pain occurs in the axilla and on top of the shoulder. Above the horizontal, there is no pain but the whole arm feels "heavy," and the humerus falls forward to the side of the face. At about 60° of abduction, the scapula begins to rotate with the humerus. Adduction is complete. The patient has noticed she has more power to use the forearm if she closely and forcibly adducts the arm. In putting the hands behind the back, movements are slow, feeble and painful. She can barely clasp her hands in the median line behind; cannot fold the right arm with the left behind her back. Rotation limited and painful, both internal and external. Flexion of forearm on arm is weakened if the forearm is first supinated (to eliminate the flexor action of the supinator longus).

The co-ordinate action, of whose incompleteness she complains, that is, reaching behind to button her skirts, is arrested about midway. She slowly partially abducts the arm, flexes and pronates the forearm, flexes the wrist and hand on the ulna, and then slightly rotates the humerus inwards so that the back of the hand lies against the lumbar region, just above the crest of the ilium. Here the action is arrested by the increasing weakness and pain in the shoulder, deltoid region and along the dorsal and flexor aspects of the radial side of the forearm, and the arm falls heavily to the side.

The range of passive is about the same as of active movements, the limit being marked by the same pain referred to the deltoid region, bend of elbow, acromio-humeral and upper and outer scapular regions. When the arm is abducted two-thirds of the distance to the horizontal, the scapula moves with it in further abduction and in returning adduction. Rotation of the humerus is limited, particularly outward.

Electrical Examination.—Comparison made with left side. Nerves (in supra-clavicular fossa), with both faradism and galvanism: Passage of the current is more painful than on the other side; diminished irritability of deltoid, biceps and rhomboids; no response in serratus magnus.

	MUSCLES.	
	Faradism.	Galvanism.
Deltoid . . .	Diminished.	Increased in anterior; diminished in posterior; sluggish contraction and increased A C C in all parts of the muscle.
Biceps . . .	Diminished.	Diminished, with increased A C C.
Triceps . . .	Normal.	Increased.
Supinator . . .	Normal.	Increased.
Rhomboids . . .	Diminished.	Diminished, with increased A C C.
Serratus Magnus . . .	None.	None.

¹ Read before the Section on General Surgery of the New York Academy of Medicine, May 11, 1896.

² A full report of these cases will be published in the Transactions of the New York Academy of Medicine, 1896.

³ In no case did I find the brachialis anticus completely paralyzed; but in several cases, owing probably to its double nerve-supply, the results of its examinations were not sufficiently satisfactory for me to be willing to place them on record. I have, therefore, uniformly omitted them from the reports.

The examination of this patient shows a faulty action of nerves, muscles and the shoulder-joint.

Nerves.—Pain, tenderness and parasthesia show irritation somewhere along the course of the sensory nerves. The motor nerves involved, separated from the muscles to which they are distributed, are accessible only in the supra-clavicular fossa, and even there it is not always possible to isolate separate trunks. However, at and near the supra-clavicular point of Erb (Remak, Hoedemaker), it is in all cases possible to get reactions from different combinations of muscles. Examination of the grouped trunks of the motor nerves in this situation showed a diminished conductive power to both faradic and galvanic currents to some of the muscles about the shoulder, while those of the forearm and hand responded as vigorously as on the other side.

Muscles.—In analyzing the impairment of motor power in the various actions of the shoulder, the most prominent factor is the failure of the rhomboids and serratus magnus to keep the scapula applied to the thorax, and to fix it for the movements of the arm. Every one of the muscles which fails in this case to act properly has one of its extremities attached to this too movable scapula. Hence, from this fact alone it would be impossible to say there was any fault in the shoulder muscles themselves. But, on testing them individually, more or less marked nutritive changes are found,—the quantitative and qualitative electrical changes which accompany a motor lesion and which correspond with the electrical changes mentioned as occurring in the nerve trunks. These changes are most marked in the deltoid⁴ and biceps. In addition, measurements show each of these muscles to be one centimetre smaller than on the unaffected side, and as the right arm is usually larger than the left, this would indicate an atrophy of certainly more than one centimetre.

Shoulder-Joint.—But there is still another element interfering with the action of the muscles around the shoulder. There is an abnormal connection between the scapula and the humerus, so that when the humerus is abducted to about 60°, the scapula rotates with it in further abduction, and returns with it to the same point in adduction. "In normal abduction and adduction," to quote Morris,⁵ "the scapula is fixed and the humerus rolls up and down upon the glenoid fossa. During abduction, the head descends until it projects beyond the lower edge of the glenoid cavity, and the greater tuberosity impinges against the arch of the acromion. . . . The greater tuberosity by striking against the acromion process and coraco-acromial ligament stops short any further advance of the bone in these directions, and thus abduction ceases altogether as soon as the arm is raised to a right angle with the trunk. Further elevation of the arm beyond a right angle is effected by the rotation of the scapula round its own axis by the action of the trapezius and serratus magnus upon the sterno-clavicular and acromio-clavicular joints."

In the present case, the normal rotation of the scapula with the humerus is anticipated, taking place at 60° of abduction. There are two possible causes for

such a changed mechanism. Taking for a basis the physiology of the joint movement in abduction, which I have just quoted, the rotation of the scapula would be anticipated (1) by any impediment to the rolling down of the head of the humerus upon the glenoid fossa, or (2) by any obstruction to the rise of the greater tuberosity. But the problem is not so simple as is implied by the consideration of these primary elements only; the action of these bones depends on that of many accessory tissues. Quain touches upon some of the complicating conditions when he says: "The arch formed by the acromion, the coracoid process and the deltoid ligament, lined by the subacromial bursa, forms a sort of secondary socket in which the extremity of the humerus, covered by the tendons inserted into the great tuberosity, revolves." Sappey,⁶ speaking of the humeral head descending below the glenoid cavity, says it comes into contact with the capsular ligament and projects into the axilla. Again, he says: "As the arm approaches the horizontal, the great tuberosity begins to be engaged beneath the acromion. . . . Its displacement is peculiarly favored by the subacromial bursa. . . . The upper part of the capsular ligament and the accessory ligament are pressed back behind the coraco-acromial ligament in a celluloadipose space, which is limited below by the supraspinatus and above by the outer extremity of the clavicle."

But even this does not cover all the ground, for the agent upon whose activity and co-operation all this mechanism depends is the deltoid muscle, and its practical relations with the humerus begin at its insertion into the middle of the outer surface of the shaft of this bone. From this point it passes upward like an inverted hammock, broadening rapidly as it ascends; it covers the upper half of the outer surface of the humerus and all contiguous structures, the greater tuberosity, with its attached tendons, and the outer part of the capsule. It does not follow the capsule and the head of the humerus into the coraco-acromial vault, however, but leaping upward over the coraco-acromial arch, it covers the coracoid process and the coraco-acromial ligament and becomes firmly attached to the acromion process, the scapular spine and the clavicle. Its under free surface glides readily upon the structures covered by it and attached to it by a very loose, bursoidal tissue. (According to most writers, the bursal tissue is distinct, with well-defined walls and cavity.)

With this view of the region involved, it is evident that abduction is a very complicated and extensive action, requiring not only the integrity of the joint surfaces and their enclosing capsule, with its synovial lining, but also the integrity of all the external tissues which by their actions upon, or relations to, this capsule might influence it; and, even further, the integrity of the muscles which abduct the humerus, and of all the tissues which, internally or externally, might influence the action of these muscles. Hence, a locking of the scapulo-humeral joint during the movement of abduction may have its cause located anywhere along, or accessory to, the curve beginning at the deltoid insertion, running up to the coraco-acromial vault, curving over along the head of the humerus and the glenoid cavity and terminating in the axilla below this cavity.

⁴ It is interesting to compare the study, given under the heading of voluntary movements, of the attempt of the patient to button her skirts behind her, with Duchenne's description (*Physiologie des Mouvements*, Paris, 1867, pp. 62, 64) of paralysis of the posterior deltoid.

⁵ Morris: *Human Anatomy*, Philadelphia, 1895.

⁶ Sappey: *Traité d'Anatomie Descriptive*, third edition, Paris, 1875, i and iii.

Now, abduction is not a simple action of the abductor muscles, but when such action is desired, a more widely diffused impulse is sent out in several directions, principally to the serratus magnus and trapezius, as well as to the abductors of the humerus. When there is any impediment in the abducting path, that is, the curve described above, the impulse to the serratus magnus and the trapezius continues and, in response to this, the factors of the stage of hyperabduction (that is, beyond 90°) supplement the deficient abduction proper (to 90°), the rotation of the scapula is anticipated and the arm rises in abduction; but the centre for rotation of the rising arm is located not in the scapulo-humeral joint but beyond it, in the acromio-clavicular and sterno-clavicular articulations.

For all practical purposes, the impediment in the abducting path may be sought for in one of two great classes, it may be intra-articular or extra-articular, or it may be a combination of the two. If intra-articular, it must be connected with pathological variation of one or more of the constituent parts of the joint proper. These constituent parts are bone and articular cartilage, held together by ligaments which are lined by synovial membrane. Barwell,⁷ referring to the inaptness of both cartilages and ligaments to take upon themselves primarily any inflammatory action, says: "The morbid appearances and the symptoms of an isolated chondritis or syndesmitis, supposing that such affections could exist, are unknown. The pathologist never sees, and the surgeon never has reason to suspect, the existence of such diseases. It may then be taken as assured that the only maladies with which we have to do arise either in the synovial membrane, or in the bones of joints." In the patient under consideration, it is unnecessary to dwell on the question of osteitis in the absence of all of its well-known symptoms. There remains for consideration synovitis, the most probable lesion of all. Surgeons are united as to the ease and frequency with which this occurs. Many of the symptoms of this patient suggest the manifestations of synovitis, but almost without exception they at the same time show striking differences.

The history of the case is not the history of a case of synovitis,⁸ but as the patient did not come under observation till after eleven weeks, may there have been such an inflammation, nevertheless? May there even have been an arthritis, it being a well-established fact that a continued synovitis is apt to lead to more or less involvement of the other joint constituents and so cause an arthritis? And as the result of either synovitis or arthritis, have we some intra-articular adhesions binding together the scapula and humerus?

But the cause of the joint limitation may be entirely extra-articular. Again seeking an anatomical basis, we find that the extra-articular tissues in the shoulder are periarthritic cellular tissue; bursæ; muscles; tendons; deep and superficial fasciæ, enclosing nerves, blood-vessels, lymph-vessels and nodes; and, finally, integument—and the disability, if extra-articular, must be due to such pathological changes in one or more of these as to interfere with the act of abduction. It is easy, in this case, to exclude the integument, fasciæ, blood-vessels and lymph-vessels and nodes—there are no cicatrices, no gross loss of substance, no

swelling or apparent infiltration, no increase of tension or thickening discoverable in any of the accessible tissues.

The muscles, tendons and fasciæ show no rigidity, no spasm or contraction. The muscles do, indeed, give evidence of nutritive change; but while a weakened and painfully-acting muscle might fail to move one bone of a joint upon another, it is not conceivable that it could hold the two bones immovable except by spasm, or by wasting to such a degree that actual shortening occurred, and instead of being covered by an elastic, controlling tissue, the joint would be bound by a rigid, restricting tissue. Neither of these conditions is present.

No gross changes are found in the nerves, which, however, do show evidences of irritation and of parenchymatous change, as manifested by their diminished power of conduction, and by the quantitative and qualitative modifications in the electrical reactions of the muscles to which they are distributed. A diminished power of nerve conduction and a weakened muscular response to nervous stimuli do not, however, bind the bones of a joint together unless the same conditions obtain as we discussed under wasting of muscle, and such as do not exist here.

The bursæ and periarthritic cellular tissue remain to be scrutinized. First, as to the bursæ: it must be remembered that the shoulder-joint is in relation with several tendons and one muscle, and that the muscle (deltoid) and most of the tendons are separated from the capsule by bursæ, several of which bursæ communicate with the articular cavity.

Nancrede⁹ gives a summary of the various constant and adventitious bursæ, and mentions as most constant and important those beneath the acromion and deltoid and beneath the subscapularis and the infraspinatus.

I do not find any reports of inflammation of the subscapularis and infraspinatus bursæ, though Nancrede refers to them as likely to become secondarily affected through their anatomical communication with the joint cavity. Inflammation of the subacromio-deltoid¹⁰ bursa is well known.

Jarjavay¹¹ studied this bursa upon the cadaver. Cutting through the deltoid at its attachment and turning it upward over the acromion and clavicle he found that as the arm was abducted the walls of the bursa were puckered up, forming a pad below the beak of the acromion; and that as the humerus became horizontal, the tuberosity glided beneath the acromion, pressing inwards the bursal folds. "If the walls are normal, this gliding is done without friction and without noise, but if the walls are thickened and the cavity crossed by fibrous septa, a 'jolting' (*soubresaut*) is made and a kind of cracking. This condition is often met with in workmen who habitually exercise their arms in laborious work,¹² and in them it is easy to produce

⁹ Nancrede: *Injuries and Diseases of Bursæ*; Ashhurst: *The International Encyclopedia of Surgery*, New York, 1882, vol. ii.

¹⁰ Some writers speak of this bursa as the subacromial, but the context shows that they also understand it to be prolonged under the deltoid; others, again, refer to it as the subdeltoid and sometimes do not refer to its subacromial connection; still others say "subacromial or subdeltoid." As both relations are important, the writer would suggest that the term *subacromio-deltoid bursa* would be comprehensively descriptive and unmistakable.

¹¹ Jarjavay: *Sur la luxation du tendon de la longue portion du muscle biceps huméral*, etc., *Gaz. Hebdomadaire*, 1867, 2 s., iv., p. 358.

¹² The writer has often noticed this crackling crepitus in persons who have never done any hard work, and not infrequently in children. Barwell (p. 420) says: "It is an important circumstance that movement produces in many hysterical joints a fine, slight crackling which might mislead diagnosis; it is to be remembered that certain joints of persons, between fifteen and eighteen, the age of greatest growth, habitually crepitate in this manner. A coarser crepitation may some-

⁷ Barwell: *Diseases of the Joints*, in Ashhurst: *The International Encyclopedia of Surgery*, New York, 1882, vol. iv., p. 261.

⁸ In answer to repeated and varied inquiries, the patient is sure there was never any swelling of the joint, no spasm of muscles, no stiffness, the pain has always been the same.

this noise by abducting the humerus. When the shoulder undergoes exaggerated movements of torsion, the walls of this bursa are contused or torn, leading to an inflammation with tumefaction of its walls, making movement of the arm painful, hence immobility, hence also the cracking, the 'jolting,' which is occasioned by the movements of elevation and abduction, and of rotation of the humerus when the latter is horizontal; and, finally, the sense of a reduction as if there had been something displaced in the shoulder."

(To be continued.)

CLIMATE OR ENVIRONMENT AS A FACTOR IN THE REPAIR OF NEURASTHENIA AND MELANCHOLIA.

BY JOHN MADISON TAYLOR, A.B., M.D., PHILADELPHIA.

THERE is a strong belief prevalent among the profession of medicine and the laity alike, that climate exerts a marked influence for good or ill upon persons suffering from brain-fag, nerve-tire and melancholia. It is my desire to call attention to the subject before this experienced body of widely scattered and acutely observing medical men, especially familiar with climate and its effects, which I hope will provoke a discussion and bear fruit now or a year hence, when I propose again to reopen the matter. If one or another climate does help or hinder these sufferers, it is important to know the fact and accumulate and sift the evidence; to note the effect of altitude, sea-level, heat and cold relations, humidity, winds, and the like, characteristics of soil, flora, and whatever factors go to make up that subtle entity, a suitable dwelling during special forms of debility.

The writing of climatologic experts has hitherto been directed almost exclusively to the needs of sufferers from pulmonary, asthmatic, rheumatic or other sensitive ailments. The martyrs to these ills have superadded not seldom the complicating factor of neurasthenia, and it would be instructive if these could be differentiated and considered separately. However this may be, one fact is thrust upon the attention of American physicians obtrusively: the increasing number and complexity of instances of exhaustion, with will loss or impairment, mental depression and other effects of modern hurry, strains, responsibility, coupled with excesses of various sorts, not always intrinsically reprehensible, oftentimes praiseworthy, accidental or inevitable. A large part of these persons refuse systematic medical treatment, but are quite willing to "try a change of climate," which they often prescribe for themselves; they act during their wanderings as they choose, seldom wisely, and return when it is convenient, or make such changes as fancy or whim may dictate. It is worse than unfortunate that the public are guided less than they were by medical advice in these matters, valuing the opinion of a presumably skilled and learned professional man less in matters of general conduct than the views of clergymen, who are so often valetudinarians trying a new region each summer, or the ideas of accidental acquaintances. They talk a vast deal of rubbish on their return about their experiences and conclusions. We medical men thus suffer in our dignity and influence, and the public

make a lot of blunders oftentimes most disastrous for themselves. However, it is our own fault largely, and this we should seek to remedy, first, by being at greater pains to know, and, secondly, by giving definite, clear and forceful reasons for our opinions. We really know very little of the climatic possibilities of America, and as to those of Europe we are guided chiefly by hearsay or ancient precedent. It is not permitted the average medical man to roam for his own instruction among health resorts, and when he turns to literature he is too likely to find interested plaudits based upon reasons more or less commercial. We then need, most conspicuously, formulated information as to our own climates. This knowledge is, however, growing steadily, thanks largely to the efforts of this Society. It would be greater if concerted effort in the search for, and interchange of, opinions were more systematic and frequent.

I personally have been fortunate in seeing a large number of health-resorts in four continents, and am thus enabled to form some opinion as to their charm and especial equipment. Also, I have been enabled to judge somewhat of their suitability to the class of cases under discussion, because my experience of these localities has been largely on account of certain sufferers from nervous disturbances with whom I was thus travelling. I offer here, for comparison with the views of others, a few conclusions from this and also a pretty large subsequent experience gained at second-hand from patients of my own, and also from the nurses or attendants, upon whose conclusions I am much more apt to depend. One fact stands out more boldly than any other. Environment is, for these folk, of far deeper influence than locality, and as the first factor is always much more controllable than the latter, upon it the medical adviser must chiefly depend in the majority of cases. Environment includes many important things, the first of which is suitable companionship, most often solved by a proper paid attendant, preferably a skilful and tactful nurse. With such a companion it is not necessary, often objectionable, to stir far from home. Plenty of places can be found within a few miles of one's own residence admirably adapted to all reasonable requirements. Then, if from home, there follow a number of desiderata connected with creature comforts which are often interpreted by the patient to mean palatial hotels of mammoth size, with a bewildering array rather than special suitability of dietary. However, even herein a judicious selection need not go amiss, the province again and duty of one other than the patient.

There are doubtless many advantages to be claimed for radical geographical changes, escape from a cold winter being one of the most conspicuous and popular. The warmth and sunlight of subtropical regions afford opportunity for outing which cannot be gainsaid, but it is a question whether the reversal of the seasons is so well for those who are lacking in vascular and nervous tone for whom cold, under suitable precautions, is an invaluable tonic. Indeed, I have repeatedly seen evil effects, lack of gain and changes for the worse, from the occasional excessive heat and emasculating softness of the sunny South. I accompanied a gentleman to the tropics, whose trouble was the result of simple protracted overstrain, who suffered intensely from the enervating qualities of the heat and lifeless air. A change to a cool hill country, where we kept busy and active in a simple physical way, wrought a

times be detected in old, long-standing cases of hysteric malady, more especially in such as have been treated as though affected with real disease."

notable improvement. And so it often is, the inaction of unseasonable heat, theoretically restful, is galling to an active mind and body, which require a change of form in the lines of normal impulses rather than a checking off of these, or an enforced inactivity induced by depressing heat, which so frequently occurs in sub-tropical winters. Again, it is a great evil for the physician to assume that because he personally happens to enjoy the seacoast, and himself sleeps well when there, that a man, all tingling with jaded and irritated nerves, and sleepless from worries and hyperemic brain-states, must also be similarly benefited. The small repeated noises which make up the roar of the sea are sometimes revolting to such sufferers. There is also another element in seashore air—the small repeated concussions on the eardrums caused by the ceaseless beat of air-waves; also a certain vibratile influence, due to the beat of the surf on the shore, which the patient also shares, possibly, by a species of bone-conduction to the brain. All these are small points, it may be, but in the aggregate most unpleasant. Many persons are persistently sleepless at the seaside; some, indeed, are never well when on the surface of the sea, though not actually nauseated. They suffer from sea dyspepsia. I have an intimate friend who was retired from the navy because of an unconquerable inability to digest while on board ship, although never seasick.

Mountains, again, are charming to see and invigorating to climb, but to remain long in high altitudes occasionally produces harmfulnesses, especially to those lacking in vascular tone. The nervous distress due to aerial rarefaction is recognized, though perhaps not yet fully understood. As a rule, it seems to me high altitudes aid apathetic states, and are liable to produce restlessness in irritable folk.

Let me call attention finally to the great unwisdom of allowing a sufferer from the effects of diseased impulses to rush helter-skelter from place to place, like the dove when she escaped from the ark, ever seeking rest, and finding none; or, *per contra*, the sufferer from will-loss who becomes apathetic or melancholic, choosing obstinately to stick in one spot into which he may drop by accident, declining to budge unless forcefully urged to do so on rational grounds or pure and simple domination.

NOTE.—It would aid the writer more materially to receive communications from those who have experience on this subject from which he may construct a paper to be read before the Climatological Society next year. Address Dr. J. M. Taylor, Bar Harbor, Me., or 1504 Pond Street, Philadelphia, Pa.

Clinical Department.

REMARKS ON THE TREATMENT OF TUBERCULOSIS BY THE ANTI-TUBERCLE SERUM.¹

BY GUY HINSDALE, A.M., M.D., PHILADELPHIA, PA.

It has been ascertained that if a living culture of tubercle bacilli is injected into the veins of very old mare mules, they will succumb to the disease in from the seventieth to the ninetieth day. Experience shows that if they pass over the ninetieth day they get well. By the one hundredth to the one hundred and tenth day the tubercle bacilli fade away, and even the

tubercular nodules become lost. Tuberculin is present up to the one hundred and fifteenth day; but by the one hundred and thirtieth to the one hundred and fortieth, the tuberculin is entirely absent, and the largest amounts of the anti-tuberculin are present. At the one hundred and thirtieth to the one hundred and fortieth day, there is no tuberculin reaction; but the serum has the highest protective and curative properties.

The ass and the mule bear the injection of the tubercular products with a remarkable immunity. As to inoculation beneath the skin, there is only slightly appreciable reaction, except with strong doses of an emulsion of these products. It is manifested by tension, heat and sensitiveness at the point of inoculation, during a period varying from four to six hours.

In intravenous inoculation by the auricular or jugular vein there is no microscopic phenomenon, local or general, except a slight reaction of 1° C., in case of abundant injection.

This immunity persists for inoculations more and more virulent and in greater quantity. The inoculations were repeated as many as six times on the same subjects, and at intervals, at first great and then shorter.

It has been found that the serum of the blood of the ass and mule, treated in this manner, is perfectly harmless for normal as well as tubercular animals; and that there is constant competency of this serum, presumed to be antitubercular, in antagonism to tuberculosis of human origin when administered in the case of the guinea-pig and rabbit.

The post-mortem examination of animals thus treated showed that in the different organs a barrier of fibrous tissue enveloped the tubercular granulations; the lymphatics in the neighborhood were hypertrophied and ganglions were numerous.

The serum of the ass and mule not subjected to treatment has a weaker antagonistic action than in the case where treatment has been used. That the action is strongest with the serum of animals treated at moderate intervals by feeble doses of tubercular emulsions at a high virulence.²

Boinet made experiments on guinea-pigs, in doses varying from six to sixteen centimetres. Most of the immunized animals remained immune. He advises, in the human subject, the use of two to four cubic centimetres of the serum in an injection; he has treated eight patients in this manner. In three cases of slow tuberculosis, apyretic with crackling, the results were quite favorable. A marked amelioration was noted in two cases of tuberculosis in the second stage.

The treatment is useless where cavities exist; it is injurious in acute attacks, with fever, hemoptysis, night-sweats and laryngeal complications.

Hericourt and Richet make what they term a "phymo-serum."³ They employed dogs and rabbits. The case which they report is as follows:

A woman of thirty-four, without hereditary history, became phthisical, following an injury to the lung. She had cough and occasional bloody expectorations, and chronic laryngitis. Emaciation and night-sweats present. The sputum was abundant and purulent, with enormous quantities of bacilli. Crepitant, sub-crepitant and moist râles at the apices, with dulness on percussion.

¹ Read at the meeting of the American Climatological Association, at Washington, D. C., May 5, 1897.

² Redon and Chenot: Soc. de Biol., June 29, 1895.

³ Comptes Rendus de la Société de Biologie, January 12, 1895.

On December 15th, she received one-tenth of a cubic centimetre of neo-serum; on the 18th, 20th and 27th, one cubic centimetre each day. On the 31st, two cubic centimetres. On January 4th she received two cubic centimetres, and on the 8th, three. On January 14th, bacilli were very rare. Great improvement followed this treatment.

Viquerat says that the anti-tuberculin has the power of preserving the life of a guinea-pig which has been inoculated with the tuberculin six weeks previously for a period of a year or more; and that it will cure a guinea-pig which has been infected three weeks previously.

The serum which I used was prepared under the direction of Prof. Joseph McFarland in the Biological Laboratory of the H. K. Mulford Company, Philadelphia. A donkey was first injected with mallein to exclude the presence of glands. He then received an injection of one cubic centimetre of tuberculin, and this dose was doubled every five or six days until he received 200 c.c. at a dose. Very little reaction followed. The temperature rose only one to one and a half degrees, and there was some slight local edema. After the maximum dose was given the animal was allowed to rest three weeks for complete elimination of tuberculin to take place. The animal was then bled, and the blood was allowed to stand in a refrigerator five or six days. The serum was then collected, and one-half per cent. of trikresol was added, to act as a preservative; it was then kept sealed in a cool place.

While it is too early to make any complete report of the clinical tests of this agent, I wish to record one case in which I have employed the serum, in the hope that it will encourage others to make trial of it.

The patient was a married woman of twenty-seven who had a cough in February, 1896, and began at that time to lose flesh and strength. My notes taken in March of that year are as follows: Left lung normal. Right lung: increased vocal fremitus but not marked; bronchial breathing posteriorly; slight impairment of the percussion not posteriorly; some râles at the apex. In April she weighed 120 pounds, and is losing flesh; coughs and has night-sweats. Right upper lobe consolidated. Bronchial breathing on both sides, especially the right. Increased vocal resonance.

In May, amphoric breathing on the right side; coughs badly, and has fever at night. In bed one week, and has had a hemorrhage. Is pregnant.

Confined January 1, 1897. The physical signs all point to well-established phthisis.

I chose this case as being a test of the efficacy of any treatment, and had the sputum examined, which resulted in the discovery of a large quantity of tubercle bacilli.

January 16th. Temperature 98.5°. Injected five minims of the serum.

January 17th. Temperature 98.5°. Injected 10 minims; on the 18th, 20th, 22d and 24th, 15 minims; on the 29th, 30 minims; on the 31st, 40 minims.

March 2d. Injected 40 minims; on the 9th, 20 minims.

March 25th. Weight 127 pounds. Has had some soreness below the left apex and in the back.

There has been no rise of temperature and no unpleasant effects of any kind. All the injections were made in the left arm near the insertion of the deltoid, after carefully cleansing the part. There has been general improvement in all respects. The bacterio-

logical examination on March 9th and 15th showed absence of tubercle bacilli.

Examined May 2, 1897. Percussion note clear all over the chest, front and back; breath sounds clear; no râles. The only abnormal sign is a slightly increased vocal resonance over the right apex. The patient is steadily gaining weight and strength, and has little expectoration. The progress of the case will be reported to the Association next year.

THE USE OF TINCTURE OF IODINE IN CHRONIC TRACHOMA AND PANNUS.

BY WILLIAM E. BAXTER, M.D.,

Ophthalmologist to the Boston Dispensary.

SOME time ago the writer's attention was called to the use of the tincture of iodine, in ulcers and suppurative conditions of the cornea, such as are usually treated by the galvano-cautery; and since that time this method has been used exclusively in these conditions, as the iodine penetrates more thoroughly to the limits of the diseased tissue, is fully as effective as, and leaves less scar than, the galvano-cautery. After watching the action of iodine in clearing up the cornea in these cases, it occurred to the writer to use this agent in other troubles of the cornea; and so the following method of treating chronic trachoma and pannus resulted: the application of a moderate amount of equal parts of tincture of iodine and glycerine to the everted lids, then turning the lid back without removing the excess of the remedy.

This method is applicable to chronic cases, and under its use the granulations melt down, the mucous membrane resumes a normal appearance, and the cornea clears, better than under any other method that the writer has used.

The application is painful, and cocaine should first be used; the applications should be made as often as two or three times a week.

Medical Progress.

RECENT PROGRESS IN OBSTETRICS.

BY CHARLES W. TOWNSEND, M.D., BOSTON.

PUERPERAL FEVER IN PRIVATE PRACTICE IN ENGLAND.

DR. CHARLES J. CULLINGWORTH¹ presents some alarming statistics in his inaugural address before the Obstetrical Society of London showing conclusively that puerperal fever, far from having diminished in private practice in England and Wales, has considerably increased. He cites the percentage of deaths from puerperal fever from 1847 to 1895. In 1847 it was 1.5 per 1,000 births, remaining below 2. with only seven exceptions, until 1881. During and since that year, the mortality has varied from 2 to 3.3 per 1,000, the latter figure being reached in 1893. If, as he says, the figures err, they err in the direction of being below the truth, not in excess of it. In London the total death-rate from childbirth has considerably diminished. The diminution is due, however, not to any appreciable lowering of the mortality from puerperal fever, but to a lessened mortality from the acci-

¹ Lancet, March 6, 1897, p. 643.

dents of childbirth. In the provinces, the total death-rate remains practically unaltered; but whilst there has been a diminution in the mortality from the accidents of childbirth, the mortality from puerperal fever has increased to such an extent that, instead of being accountable for less than a third of the total mortality, it is now accountable for more than one-half. The prevalence of puerperal fever he shows to be dependent, not on the density of the population, but on the character of the medical attendance. In some districts ignorant midwives are largely employed, and often spread the disease broadcast.

Two maps of London are given: one showing the density of the population, the other the relative incidence of puerperal fever. The lack of correspondence in the two maps is very marked. Hampstead heads the list in the largest proportion of cases of puerperal fever, while St. Giles, Strand and St. Luke are at the other end of the list, and St. Martin in the Fields has reported no deaths from the disease from 1891 to 1895.

Why is it, he asks, that while puerperal fever has become a thing of the past in our lying-in hospitals, there has not been a corresponding diminution in private practice? It is because of the ignorance of midwives and the carelessness of medical men in antiseptic details, both of which should be remedied.

ANTISEPTIC MIDWIFERY IN THE LONDON LYING-IN HOSPITAL.

Dr. Clement Godson² in a valedictory address before the British Gynecological Society compares the results at the City of London Lying-in Hospital from the time he became connected with it in March, 1870, up to the end of April, 1886 (a period of 16 years), with that beginning July 1, 1886, when corrosive sublimate as the antiseptic came into use there, up to December 31, 1896 (a period of 10½ years). Early in 1870, out of 227 women delivered, 12 died, or 1 in 19. Notwithstanding many sanitary alterations in the building, frequent closures of the hospital were required from the increasing prevalence of puerperal fever. Thus, in the two years 1882 and 1883, the mortality was 1 in 23. On July 1, 1886, the hospital was reopened, corrosive sublimate being used as an antiseptic. The first 420 confinements took place without a death; and in the 10½ years since then, out of 4,608 deliveries only 11 deaths from all causes have occurred. In the last five years, out of 2,392 deliveries, no death from septicemia has occurred.

Thus it will be seen that architectural arrangements, drainage, ventilation, segregation and drugs had all been tried, and without success. Antiseptics alone had brought success.

SERUM TREATMENT OF PUERPERAL SEPSIS.

Barton Cooke Hirst³ reports three cases of puerperal sepsis treated by anti-streptococcic serum. The first case promptly recovered; the second case grew steadily worse, and died; and the third case showed alarming symptoms after each injection, but recovered. Hirst does not believe we are in a position to pronounce any judgment in this new treatment.

The following objections may be urged against the treatment with considerable force:

(1) The well-tried older plans of treatment will

result in a cure of about four-fifths of the cases; hence recovery may be attributed to the serum when it was really due to some other form of treatment.

(2) It is difficult to procure a thoroughly reliable preparation of the serum.

(3) The use of this remedy must be always more or less empirical, as there are a third or more of cases of puerperal sepsis in which there is a mixed infection, or in which the infective agent is not the streptococcus at all. A bacteriological examination of the uterine discharges is not enough to solve this question.

(4) The treatment is not entirely free from risk.

(5) There is some danger that too great reliance for a time might be placed upon this form of treatment to the neglect of older, better tried, and perhaps more successful plans.

(6) No one yet knows how this remedy acts; if it simply produces a hyperleucocytosis, there are other and simple agents which will have the same effect.

These objections, however, are not so weighty as to forbid his giving the method an extensive trial in the future.

Richard C. Norris⁴ reports a case of severe puerperal septicemia where thorough and repeated local and general treatment had no effect in checking the disease. Vomiting supervened. Profound depression and the peculiar appearance of grave septic absorption were present to make the outlook glowing. The temperature was 105.8° F., and the pulse 144. Ten cubic centimetres of Marmorek's anti-streptococcic serum were injected. The effect of the serum was very marked. Within twelve hours the temperature fell to 98° F., and the pulse to 96. The local changes in the cervix were most decided, the swelling and induration and pseudo-diphtheritic exudate almost wholly disappearing. Seven other injections were given and the patient in six days seemed to be getting well rapidly when she was attacked by facial erysipelas to which she was subject. In five days under the use of the serum the temperature and pulse again reached normal.

G. E. Shoemaker⁵ reports a case of puerperal septicemia following abortion, where the patient was not seen until she was in the last stages. Local treatment as well as an injection of ten cubic centimetres of Marmorek's anti-streptococcus serum were employed but death occurred in three days. Cultures from the autopsy showed no streptococci, but a pure culture of what proved to be probably the colon bacillus, was found in the infected corpus luteum.

Edward P. Davis⁶ reports a severe case of puerperal sepsis where the uterus was cleared of decomposed placental tissue by a curette, was douched and packed with iodoform gauze. The next morning the temperature had fallen somewhat, but the patient continued alarmingly weak. Marmorek's serum was injected with immediately favorable and remarkable results, and the patient went on to a complete recovery.

In two other cases the serum, as well as local and general treatment, was employed; but both patients died.

Dr. J. M. Baldy⁷ reports a case of puerperal sepsis, with lymphangitis and phlebitis, where the patient was not apparently critically ill. After the first injection

⁴ American Journal of Obstetrics, May, 1897, p. 629.

⁵ Loc. cit., p. 637.

⁶ Loc. cit., p. 642.

⁷ Loc. cit., p. 645.

² Lancet, January 13, 1887, p. 221.

³ American Journal of Obstetrics, May, 1897, p. 625.

tion of serum her temperature went above 106°, still higher after a second injection; and death occurred within a few hours.

Dr. John B. Shober⁸ presents an analysis of 21 cases of puerperal sepsis, collected from the *Lancet* and the *British Medical Journal* for 1896, treated with anti-streptococcic serum. In these there were 17 recoveries and four deaths, a mortality of 19.04 per cent. This is a decided improvement over the mortality reported by Charpentier of 42.5 per cent. in 40 cases.

He concludes, that, in order to obtain the best results, it is of prime importance to secure a reliable serum. The case should be one of unmixed infection, and the injections ought to be begun immediately upon the onset of symptoms. It is highly important to apply intra-uterine and vaginal medication in connection with serum treatment.

Walter Edmunds⁹ reports a case where it is his belief that the anti-streptococcus serum saved the patient's life. Here there was pus in the knee-joint, which proved to contain streptococci, and surgical treatment was not had recourse to till some time after the administration of the antitoxin, and great improvement had already occurred. Until the antitoxin was used the patient was so ill that it was thought doubtful whether she would recover.

DRESSING FOR THE UMBILICAL CORD.

Samuel W. Lambert¹⁰ reports an epidemic of umbilical sepsis in the new-born, occurring at the Nursery and Child's Hospital, New York. Out of 169 children born there during 1896, 18 had sepsis starting from the umbilicus, and five of these died. He concludes that the question of prophylaxis against infection of the navel depends on, first, the adoption of means to hasten the drying of the stump of the cord; second, the prevention of the access of bacteria to the umbilical ulcer. He believes that the importance of the first has been lost sight of. All drying powders and dressings which hinder the free access of air delay the process of mummification and increase the risk of sepsis. Experimentally he discovered that stearate of zinc powder permitted the cord to dry up quickest, and gauze was preferable to absorbent cotton.

THE DIAGNOSIS OF EARLY PREGNANCY.

Dr. Wm. T. Gardner¹¹ makes the following observations on the diagnosis of early pregnancy in 75 cases. The value of the sign of "morning sickness" he considers very much overestimated. A typical morning sickness is not infrequently met with in patients who have a uterine displacement or an extensive salpingitis. The breast signs are most constant and most reliable in those pregnant for the first time. The enlargement of the papillæ comes the earliest, and is the most constant and easily recognized. Enlargement and tenderness on pressure are very early and constant signs. The fat breast is large, soft and, even in primiparæ, is more or less pendulous, while the breast of early pregnancy is firm and stands out from the chest wall.

By the end of the third month milk is present in nearly all cases. Pigmentation of the areola

never entirely disappears and thus this sign is of very little value after the first pregnancy. The blue discoloration of the vagina he considers of great value in the later stages of gestation. In 75 cases under three months he detected it 15 times.

The velvety feel due to the superficial softening of the vaginal portion of the cervix he found in all of the 75 cases. A similar condition is, however, found in some of the inflammatory conditions of the uterus. In a very large percentage the uterus was found tilted forward. The most important of all signs in the early months, and one, without which he does not make a diagnosis, is the cystic feel of the uterus. Practically a cystic uterus is always a pregnant uterus. There is, however, one exception to this statement, — a cystic fibroid will give nearly the same sensation as a pregnant uterus. The variety of the cystic fibroid, its comparatively slow growth, and the absence of other signs of pregnancy make the diagnosis clear.

TREATMENT OF PLACENTA PREVIA BY CHAMPETIER DE RIBES' BAG.

Dr. G. F. Blacker,¹² in a paper on the use of this appliance, observed that in the more severe cases of hemorrhage from placenta previa, this bag might be employed in place of version, by introducing it into the amniotic cavity after rupture of the membrane. Used in this way, the bag acted both as a tampon in arresting the hemorrhage, by pressing the separated portion of the placenta firmly against the uterine wall, and also as a dilator of the cervical canal, and a very powerful stimulus to uterine contractions. He had treated five cases of placenta previa in this way, and had collected 17 other cases similarly treated. He showed that in only one case did severe hemorrhage occur after the introduction of the bag; that such hemorrhage might, as a rule, be readily controlled by traction upon the bag, that in none of the cases was any difficulty experienced in introducing the bag, nor was any preliminary dilatation of the cervix necessary; and that the average length of time required for the complete dilatation of the cervix after the introduction of the bag was five hours and ten minutes. Of the mothers all recovered but one that died of sepsis. Of the 22 children, 14 were born alive and 8 dead. Of the 14, 4 subsequently died, giving a total mortality of 54.5 per cent.

The advantages claimed for the bag were:

- (1) Ease and facility of introduction.
- (2) The certain arrest of the hemorrhage.
- (3) Any further hemorrhage controllable by traction upon the bag.
- (4) The bag and not the child's body dilates the cervical canal.
- (5) The ease of delivery after expulsion of the bag.
- (6) The fact that the bag is a very powerful stimulus to uterine action.
- (7) The lessened fetal mortality, as compared with the results obtained by version.

SUPERFETATION.

H. W. Mills¹³ reports a case of delivery of a sixteen weeks' fetus, together with a perfectly fresh healthy ovum of about seven weeks. The patient, forty-two years old, had had only one previous pregnancy, which resulted in an abortion at three months.

⁸ Loc. cit., May, 1897, p. 647.

¹³ Lancet, March 13, 1897, p. 736.

She had had three periodical discharges of blood during the present pregnancy.

ON THE ACTION OF ERGOT ON PREGNANT WOMEN.

Lombe Aithill,¹⁴ master of the Rotunda Hospital, Dublin, sums up his experience with ergot, which he gives in combination with strychnine, as follows:

(1) That when administered previous to the termination of pregnancy in the case of women in whom a tendency to post-partum hemorrhage is known to exist, it tends in a marked manner to prevent the occurrence of hemorrhage.

(2) That when so administered in ordinary doses, it does not produce any injurious effect on either mother or child, and that its exhibition seems to delay the commencement of labor in such cases.

(3) It tends to make the involution of the uterus more perfect, and lessens the chance of the occurrence of subsequent uterine troubles, many of which depend for their cause on imperfect involution of that organ.

(4) It will not bring on premature labor or induce abortion unless uterine action has previously been set going.

(5) In cases of threatened abortion its administration frequently seems to act as a uterine tonic, and in some cases tends to avert the danger of a miscarriage, provided the ovum be not blighted.

(6) That, if the ovum be blighted, and especially if it be detached, ergot usually hastens its expulsion.

MANAGEMENT OF TWIN LABORS.

Stephenson¹⁵ concludes that the life of the second child is greatly imperilled if the labor be prolonged over half an hour after the birth of the first child. The infant mortality of the second half-hour after the birth of the first child is four times greater than that of the first half-hour. In the cases he analyzes it is found that the mortality in the second-born of twins is large if the head presents. When the second child was either transverse or a footling, none were lost. In a word, the mortality for mothers and children will be rendered as little as possible if the second child is extracted immediately after the first is born.

THE RELATION OF ACETONE TO ECLAMPSIA.

Drs. J. A. Clark and T. L. Skelton¹⁶ report two instructive cases bearing on the etiology of eclampsia. In the first case severe eclampsia occurred where renal insufficiency did not exist. Renal inflammation showed itself at the same time that the premonitory signs of poisoning appeared, reached its height after the cessation of eclampsia, and then rapidly improved, thus indicating that the renal inflammation was secondary to, and caused by, the same poison that produced the eclampsia. In the second case there was a severe nephritis, evident renal insufficiency, but an active liver and no eclampsia, seeming to show that the kidney disease is not the cause of the eclampsia, but a result of the elimination of a poison. The writers find acetone in the urine in these cases, indicating abnormal decomposition of organized proteids.

In eclampsia, then, there is primarily the non-elimination of the products of retrograde carbohydrate metamorphosis, and these products undergo further decomposition with development of convulsive poisons and acetone. In non-nitrogenous elimination the waste

products from the fetus in addition to those of the mother are sufficient to irritate the liver cells, with the production of the peculiar fatty degeneration. When this irritation is sufficient to cause more or less complete non-elimination the waste products quickly accumulate and undergo those changes which result in eclamptic poison and acetone.

This theory accounts for the fact that the best results in treatment are obtained from hepatic stimulants and cholagogues. Carl Braun has for his routine treatment a pill of aloes and colocynth, from which he reports unusually good results. The poison originates partly in the fetus; how else can we explain the cessation of convulsions after the death of the fetus, even though retained in the uterus, or after delivery of the child. Those cases of eclampsia occurring during and shortly after labor are caused by the contraction of the uterus forcing suddenly from the uterine sinuses the blood, which is loaded with the result of tissue changes in the fetus, into the maternal circulation; inasmuch as the systematic examination for acetone has never been made, its exact relation to eclampsia and its prognostic importance have not been determined. Its relation to tissue changes is such that no examination of the urine of pregnant women is complete without an examination for acetone.

ACETONE IN THE URINE OF PREGNANT PATIENTS AS AN INDICATION OF FETAL DEATH.

Kuapp¹⁷ reports ten cases of fetal death in which acetone was found in the urine of the mother during and for three days following labor. Half of these cases were syphilitic, but the influence of syphilis on the presence of acetone is not known. Jaksch's method of testing for acetone was used.

MANUAL RECTIFICATION OF FAULTY HEAD POSITIONS.

Henry D. Fry¹⁸ comes to the following conclusions on this subject:

Occipito-posterior positions with slow engagement require rectification. First, try postural treatment; if unsuccessful, introduce the aseptic hand, raise the head, flex and turn the occiput to the front.

Brow and transverse presentations of the vertex at the brim are treated on the same principle. Face presentations at the brim must be changed by raising the head, pushing up the forehead and drawing down the occiput. If a occipito-anterior position, the head must be rotated after changing into a vertex presentation. Occipito-posterior and face presentations within the pelvis may often be treated in the same manner. By aid of anesthesia and posture the head may be raised sufficiently high to disengage it.

In favorable cases of occipito-posterior and face presentations efforts may be limited to secure extreme flexion in one case and extension in the other, until descent is completed. Rotation of the occiput or chin forward may then be accomplished.

SYMPHYSEOTOMY AT THE BAUDELLOCQUE CLINIC.

Pinard¹⁹ analyzes 95 cases of contracted pelvis occurring in this clinic during 1896, among which there were 68 spontaneous deliveries. Of the artificial deliveries there were two Cesarean sections followed by amputation of the uterus and appendages, one version, six forceps operations, four destructive operations

on dead children, and 14 symphyseotomies. The only two natural deaths occurred in the latter class, one from frank pneumonia, the other four days after delivery from streptococcus sepsis originating in the uterus not in the symphyseotomy wound.

There were no difficulties met in the operation, and no serious hemorrhage. He particularly recommends an instrument devised by Professor Farabeuf for separating the cut surfaces of the symphysis after the section. A considerable laceration of the vagina occurred in all cases that needed a secondary operation. In another case there was an abscess of the left labium majora following the operation.

As to the solidity of the symphysis afterwards, Pinard says there is absolutely nothing to be desired. All have returned to their occupations, some of them practising very fatiguing trades. He also speaks from an experience of 12 patients that have had symphyseotomy performed in two pregnancies, that the solidity of the pelvis is not compromised by succeeding pregnancy or repeated symphyseotomy. Of all the patients operated on in four years, four only present functional urinary troubles. Two in consequence of lesions of the urethra or of the bladder, and two without apparent lesions of the bladder or urethra, have incontinence of urine.

During this year five women on whom symphyseotomy had been previously performed again entered the clinic and gave birth to their children spontaneously; and he is disposed to admit, after weighing and measuring the children, that the increase in size of the pelvis due to the operation may not perhaps be only momentary.

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

PAUL THORNDIKE, M.D., SECRETARY.

MEETING of Friday, April 30, 1897, Dr. H. L. BURRELL in the chair.

DR. FRANK HARTLEY, of New York City, read, by invitation, a paper on

A NEW METHOD FOR THE REMOVAL OF DISEASED PROCESSES IN THE NECK POSTERIOR TO THE STERNO-MASTOID MUSCLE.¹

DR. G. H. MONKS: It is with very great interest that I have listened to the description and results of this new operation of Dr. Hartley's, for the removal of tumors of the neck. The plan which he has of laying bare the entire side of the neck, dividing the sterno-mastoid and removing the whole mass of diseased tissue from both triangles, and from the region under the sterno-mastoid, seems to be original. I have made a somewhat similar incision several times, but have made it rather as a matter of necessity in special cases, and have not felt that it was desirable to repeat it as a regular procedure. As for the incision, itself, the lines seem to correspond, as Dr. Hartley said, with Dr. Langer's lines of cleavage, and "Kocher's normal incision," so-called. Lifting up this flap on a hinge, as it were, enables one to see the whole field. I have several times divided the sterno-mastoid, and have al-

ways been much surprised to find that no paralysis resulted.

Dr. Hartley assures me that he has never had any trouble resulting from the division of this muscle in the slightest degree. I can hardly agree with the doctor as to the necessity of avoiding the small nerve twigs of which he has spoken. In fact, it seems to me there are only a few structures in the neck which need to be looked out for, and it is only rarely that the surgeon, who is familiar with his anatomy, wounds any of these structures. The internal jugular vein is the one important structure which is perhaps the most frequently injured. This may be torn or cut, but it is of no great consequence as the hemorrhage, though profuse, can be readily stopped, and a lateral ligature or suture be applied to the vein. This has occurred to me on two or three occasions. Once having divided a small branch of the vein, my assistant, in his haste to secure the bleeding point, grasped too much tissue in the hemastatic forceps, and then incautiously pulled upon these forceps tearing a large piece out of the vein. He had included a part of the internal jugular within the forceps without knowing it. It therefore seems to me very desirable that in these cases where there is a profuse hemorrhage, that one should, so far as possible, find the exact spot from which the blood escapes, and seize as little tissue as possible by the forceps.

The next structure most often in the way is the spinal accessory nerve. This I have never wounded accidentally, but have frequently come across it in a position where it might easily be wounded. The division of this nerve, however, would simply mean the paralysis of a part of the trapezius muscle. It should, of course, be sewn together at once. The phrenic, pneumogastric or the cervical sympathetic might be wounded, but only, I think, by a careless operator. One has also to look out for the thoracic duct on the left side which enters into the subclavian vein and the lymphatic duct on the right. I have never seen a case where either of these was wounded, although other surgeons have told me that they have seen the thoracic duct opened, an accident which was followed by an escape of white chyle into the wound, but no serious results followed. On the other hand, the books often speak of this accident as a very serious one, and one which is likely to be followed by a fatal termination.

In operating low down in the neck one should also not forget the proximity of the top of the pleura. The hemorrhage which comes from the wound in all these operations is, as a rule, not very profuse, and I think it is a good plan not to put in any ligatures at first, unless one is sure that pressure will not be sufficient. In this way, the number of ligatures left in the wound is reduced to a minimum. As for the scar which is left after these operations, accurate suturing is of great importance. Tension sutures are sometimes desirable.

Dr. Hartley has not told us about the kind of sutures which he uses, nor the methods of applying them, and I hope he will be good enough to do so. I think he must admit that the after-treatment is also of some importance — by the use of proper bandages, the accurate placing of a large and absorbent dressing with considerable pressure, and the necessity for rest general, as well as local, after the operation.

DR. MUMFORD: The paper read by Dr. Hartley is

¹ See page 469 of the Journal.

important because it puts before us in a logical and convincing way, the proper reasons for this method of operating. The thoroughness of his statements leaves unmentioned but one argument in favor of this procedure. It is conceded that the great objection to operating on tumors of the neck—and I refer especially to tuberculous glands—is the difficulty in obtaining a primary union, and, that failing, the trying experience of an exhausting, obstinate, suppurating wound. I regard the operative cicatrix so often alluded to by others as of very minor importance. In view, then, of the importance of obtaining a primary union, this large encircling incision is of the very greatest value, and for some years I have used it in suitable cases with advantage, in fact, by its use, the operation is subcutaneous. In all operations absolute skin disinfection is an impossibility, and when the underlying structures are of a disorganized pathogenic nature, a mixed infection is common when they are approached through an imperfectly disinfected skin.

By making our skin incision at a distance from the mass of disease to be removed, and then peeling back the flap with a fresh knife, there is practically no chance for a mixed infection from the cut skin, and the mass can be attacked freely in this large exposed field.

Healing of the replaced flaps also is more rapid, as the problem concerns only perfectly normal tissues; and underlying exudate does not press so directly upon the fresh scar. The line is small to a minimum and keloid is almost unknown.

DR. F. M. BRIGGS: The discussion has turned to the removal of cervical glands. As this is a subject to which I have given very careful attention and one which I have studied in detail, I wish to protest against this operation as a routine treatment. I think that such cases should be left alone until there is no further possibility of absorption. If they break down, they should be treated by the canula method which I have shown to be a satisfactory one, and one which leaves either no scar, or a minimum scar. Their removal is an operation which is undoubtedly indicated in certain cases, but one, that, in my opinion, is resorted to much more frequently than it should be. The lymphatic glands prevent further absorption. They do not infect. If the operation is called for, it should be a complete one; and as the reader has clearly demonstrated, the skin ought to be dissected back and the subcutaneous tissues divided in the most thorough manner, if these glands must be removed. But, I personally object, and think I have enough data to make this objection a valid one, to the indiscriminate operation for the removal of cervical glands.

DR. HARTLEY: This operation was not devised for cases which had not been previously given the usual treatment, both internal and local. Those cases of mixed infection resulting in abscesses confined to single glands or a number of glands (cold abscess), are often cured by either drainage or the injection of sterilized iodoform oil with or without a permanent drainage. The cases I selected as suitable for this operation were cases of caseous degeneration or abscess, or else cases of simple gland enlargement (without either caseous degeneration or abscess) in front of, beneath and behind the sterno-mastoid muscle. They were cases in which the disease could not be benefited by the treatment of one or two or a number of broken-down glands, but in which a cure could be obtained only by a complete enucleation of the entire mass, no matter whether that

mass contained sinuses or abscesses or whether it was made up of hypertrophic tubercular lymphadenomata. Surgeons see many of these cases entering a hospital, whereas the other class of cases rarely comes under their notice unless in dispensary treatment.

DR. J. H. WRIGHT showed, by means of the stereopticon, sections from a spinal cord in which an unusual tract of degeneration was present. This tract of degenerated nerve fibres was situated in the posterior column of one side of the cord and marked out the ascending path of the fibres of a degenerated posterior nerve root of the lumbar region. The case was one of metastatic carcinoma of the mamma, involving the sacrum and spinal column, which came to autopsy in the laboratory of the Massachusetts General Hospital. The patient had been operated upon by Dr. H. L. Burrell about two years previously. There was no local recurrence present at the time of death. The degeneration of the posterior root of the lumbar nerve was apparently due to its involvement in the new growth in the sacrum. The degenerated tract could be traced upward in the posterior column on the same side to the neighborhood of the eighth or ninth dorsal nerve root, where the cord showed extensive diffuse degenerative changes owing to pressure from the new growth in the spinal column. There was no evidence of a corresponding tract of degeneration extending downward in the posterior column below the entrance of the degenerated nerve root, as would be expected in the light of the present teaching of the finer anatomy of the spinal cord.

DR. E. H. BRADFORD of Boston read a paper on

DEFORMITIES OF THE FOOT IN ART,²

illustrated by the stereopticon.

AMERICAN DERMATOLOGICAL ASSOCIATION.

THE TWENTY-FIRST ANNUAL MEETING, HELD AT WASHINGTON, D. C., MAY 4-6, 1897.

FIRST DAY.

DR. JAMES C. WHITE, of Boston, opened the meeting with the

ANNUAL ADDRESS OF THE PRESIDENT,

in which the members were reminded that the Association had now been in existence for twenty years, and the work of this period was briefly reviewed.

It was claimed that the Association, through the efforts of its individual members, had contributed largely to the advances which have been made in this department. There had been read at the meetings and published 327 papers, while many important works on dermatology and several atlases by members had appeared and the data gathered were of inestimable value. Dermatology in this country can now be said to hold an independent position, and writings here can now be held to occupy a plane with those of all other countries.

The rôle of the parasite has been of late years enormously enlarged. Many dermatoses formerly confused have been given a position by themselves. New diseases have been discovered, while new methods of treatment have added to the number. Methods of cure do not, however, keep pace with the discovery and separation of individual diseases.

² To be published in a later number of the Journal.

It was suggested that the best interests of the Association called for change of time and place of meeting. The reasons for this included the present unfavorable time of meeting, necessitating a suspension of college work for a week in a very busy period of the year.

The first paper read was

A CONTRIBUTION TO THE STUDY OF BLEEDING STIGMATA,

by DR. JAMES NEVINS HYDE, of Chicago, who reported the case of an adult male subject who suffered from hemorrhages from the surface of the skin, apparently spontaneous in origin. Some of these bleedings had lasted for six months at a time. Eventually there was a shortage of 55 per cent. of hemoglobin and nearly 65 per cent. of erythrocytes. The author reviewed the literature collated under the titles bleeding or bloody stigmata, bloody sweat, hematisidrosis, Hautblutungen, hysterical stigmata, and ecstasy. There was no hemorrhage from mucous surfaces.

The paper showed that it was possible for a man up to the average in general health to develop a malarial cachexia and to show symptoms of pernicious anemia, with bleeding from a single point, and never from two points at the same time. Though dwelling in a region supposed to be free from malaria the presence of the plasmodium was shown without accompanying enlargement of the liver or spleen. There was no cycle shown in the appearance of the germ.

The case was regarded as unique.

The next paper was upon

HYSTERICAL DERMATO-NEUROSIS,

by DR. A. VAN HARLINGEN, of Philadelphia.

Four cases were reported, all occurring in young women. The lesions were bullous or excoriated after the bleb wall had been broken or rubbed off, or gangrenous. The face, chest and limbs were the regions affected. The subjects usually presented some manifestations of hysteria and were anemic.

He believed a definite process was operative, and that the term "neurotic excoriation" was too vague to cover the condition. He would also oppose the name "feigned or malingering eruption."

He referred to a previous paper on a similar subject recently presented by him before the College of Physicians of Philadelphia, and said that the present paper dealt with one variety of hysterical dermatoneurosis, the erythematous.

Erasmus Wilson had reported similar cases under the designation "neurotic excoriations."

Wilson's cases occurred chiefly in hysterical young girls. They were characterized by the outbreak of erythematous patches, with flaccid bullae, accompanied by marked sensations of burning, tingling and pain.

The question whether these eruptions were not of a fictitious character having been brought forward, Wilson had said that his own very decided opinion, founded upon a careful and anxious study of the affection, was that the eruption is not the product of malingering but that it is a well-defined form of cutaneous disease of neuropathic origin.

LINEAR NEVUS

was discussed by DR. P. A. MORROW, of New York, in a paper based upon two cases, of which colored drawings were shown, and concerning whose nature

and pathology remarks were made. The older names were objectionable in so far as they suggested a one-sidedness to the eruption, a constant nerve origin or a connection with ichthyosis.

In the instances reported, bands of verrucous raised masses extended in one from the nucha to the middle back upon one side of the spinal column and in the other from the tip of a finger over the palm, wrist and forearm to the elbow. One had existed seven and the other twelve years. There had been no signs of the affection in early childhood, though it is thought to be of congenital origin.

The histological report corresponded with that of the recognizing changes, including increase in the prickly cells, heaping up of the corneous cells, etc. The speaker thought there were several clinical varieties to be made out.

THE VARIOUS FORMS OF PITYRIASIS AND THEIR RELATION TO ERYTHEMA, ECZEMA AND PSORIASIS,

was the title of a paper read by DR. G. H. FOX, of New York, in which he took the ground that nomenclature might be simplified by including under some general and simple term like pityriasis a variety of ill-defined but similar scaly affections. He scarcely ever had occasion to use the term seborrhea, and such acute erythematous-squamous affections as occur in rings and rounded patches upon various regions of the body, some resembling eczema, some psoriasis, and some lichen, might well be brought into one general class. In the affections mentioned pityriasis rosea was included.

A large collection of photographs was exhibited upon the walls to demonstrate how closely allied clinically many of these affections are and how closely the whole group simulated the psoriasis group.

In the discussion the suggestion made in the paper was opposed on the ground that it would be a step backward.

Several similar affections have already been clearly differentiated, and thus appear on the verge of being separated. Of the former pityriasis rosea stands out by itself as presenting but little difficulty of diagnosis after one has become familiar with the type. Seborrheal eczema was also thought to be now a pretty clearly defined condition.

A DISCUSSION UPON THE X-RAYS

was participated in by DRs. GILCHRIST, BRONSON and others, illustrated by drawings of ulcers, dermatitis, periostitis, osteitis and other injuries produced by the rays now so frequently seen and reported. There is in some instances an indolent slough which does not separate for a long time. Subjects who manifest any idiosyncrasy in regard to the rays after the first exposure should be very cautiously subjected to further trial of the rays.

BLASTOMYCES.

DR. GILCHRIST exhibited microscopic specimens of blastomyces, now shown for the first time as causative agents in skin disease; also protozoa in the tissues, in caseous masses and in the stage of sporulation in cutaneous disease.

THE REPORT OF THE COMMITTEE ON STATISTICS

was made by DR. HYDE.

The returns from New York were especially meagre. Ten thousand cases were reported, a falling off of sev-

eral hundred from last year. Scabies was shown to be especially prevalent in Boston, so far as the report went.

SECOND DAY.

The officers elected for the ensuing year were as follows: President, Dr. J. N. Hyde, of Chicago; Vice-President, Dr. E. B. Bronson, of New York; Secretary, Dr. J. T. Bowen, of Boston.

New members elected were Dr. J. C. Johnston, of New York; Dr. F. H. Montgomery, of Chicago; and Dr. M. B. Hutchins, of Atlanta.

As the place of the next meeting, New York was chosen, and the time the first Tuesday in June.

The first paper of the morning session was

STRONG SOLUTIONS OF THE ICHTHYOL GROUP IN ACUTE AND CHRONIC INFLAMMATORY CONDITIONS OF THE SKIN,

by DR. H. G. KLOTZ, of New York.

The group of reduction agents, including thiol and tumenol, has usually been applied in weak solutions or combinations. The speaker has found that strong applications of this valuable class of remedies often present many advantages, even in acute conditions. They must, however, be most judiciously used and at proper intervals. They exert a decided contracting effect upon the blood-vessels and have a marked anti-parasitic influence. A point not hitherto brought out in connection with the use of ichthyol is that in a 50-per-cent. watery solution it dries rapidly upon the skin, making a protective covering without the addition of collodion or other substance to make a varnish. It had thus been found of value in acute forms of dermatitis, including that from poison-ivy, burns, freezing and traumatism. It had given good results in erysipelas, eczema and zoster; and it is thought that in dermatitis herpetiformis it will likewise be found of benefit, as well as in urticaria, dermatitis herpetiformis and the acute exanthemata.

As is well known, the chief use of ichthyol has been in those chronic states which are markedly increased in the cornification. Here often the effects of the drug are more marked if it is preceded by cauterization or strong stimulation.

In discussing Dr. Klotz's paper DR. BRONSON mentioned the fact that bichloride of mercury could be added to a watery solution of ichthyol in greater strength than it could be used in a simple solution in water. A 50-per-cent. ichthyol varnish was of great use. The groups shown in Dr. Fox's picture, being all of probably parasitic nature, would all have received benefit from this treatment.

DR. BUCKLEY spoke of the advantageous use of ichthyol internally in certain erythematous conditions.

DR. ALLEN considered that Dr. Jackson had done much to retard the free employment of ichthyol by members of the Association by his report upon the drug many years ago, in which he stated that it was of little use in dermatology. In fact, there is scarcely a drug to-day used by dermatologists of such wide application and usefulness.

THE NATURE OF THE XANTHOMATA,

was the title of a paper read by DR. S. POLLITZER, of New York.

The reader had undertaken a series of microscopic studies to determine the differences which might

exist histologically between the various xanthomas, concerning whose exact nature such diversity of opinion exists. Thirteen cases were studied by the reader, five of them being of xanthoma planum palpebrarum, four of xanthoma tuberosum, and four of so-called xanthoma diabetorum. The clinical grounds for separating xanthoma of the eyelids from xanthoma multiplex are that in the latter the nodules are round, firm, elevated papules, while the eyelid patches are soft plaques in the level of the skin. The latter, too, persist throughout life; while the multiplex form sooner or later undergoes involution. The multiplex form is rare; that of the lids common. The two forms are rarely associated in the same individual. That of the eyelids the reader claims is not a new growth, but, as his observations have led him to believe, a degeneration of pre-existing embryonally misplaced muscle-tissue. The so-called xanthoma cell is a fragmented muscle-fibre in a state of granulo-fatty degeneration with proliferation of the muscle-cell nuclei. The various stages of the change from normal muscle-fibre to xanthoma cell were shown in microscopic slides from which microphotographs were made and exhibited. This explanation harmonizes with a number of hitherto unexplained clinical and pathological facts, namely, the absence of clinical signs of tumor; its almost exclusive occurrence in the region of the face, where peculiar muscular conditions prevail; its hereditary nature; its usual development after middle life, when degenerative processes are apt to occur; the peculiar yellow pigment that is always present in muscles undergoing fatty degeneration, etc.

The structure of the eyelid xanthoma and xanthoma multiplex were shown to be essentially different. The latter forms a sharply circumscribed tumor in the cutis. It is an irritative, hyperplastic development of connective tissue whose cells produce fibrous tissue or undergo degeneration. In xanthoma diabetorum the process is more diffuse and the tendency toward fatty degeneration more marked than in the non-diabetic multiplex variety. In 85 per cent. of multiple xanthoma either diabetes or some severe liver lesion attended with jaundice was found. The author thinks it likely that further research may show that fibrous nodes and fusiform enlargements of tendons in chronic rheumatism should be classed along with the nodes of xanthoma. We would then have a large group characterized by toxemic conditions, in all of which irritative connective-tissue lesions occur in the skin and elsewhere. At one extreme of the group would stand fibrous nodes of rheumatism; at the other, the transient nodules of xanthoma diabetorum, while between them would stand the nodule of common xanthoma multiplex.

In the discussion upon Dr. Pollitzer's paper, DR. HYDE said that clinically he had seen eyelid xanthoma in a subject of diabetes. The term xanthoma diabetorum is objectionable. The glycosuria is often transient.

DR. JOHNSTON did not see how xanthoma of the lids could be classed with xanthoma diabetorum. Against the latter being a new growth is the fact that the lesions can disappear and exacerbate coincidentally with decrease or increase of the sugar in the urine.

DR. MORROW spoke of the tendency of recurrence after the removal of lesions by treatment. He believed there was a causal connection between the

presence of sugar and the development and exacerbations of the lesions.

DR. ALLEN said that in a paper presented last year he had advocated the use of the term glycosuric dermatoses instead of diabetic for these lesions since true diabetes was often not present.

DR. BOWEN said the theory of the xanthoma cells was a very plausible one. If transition forms could be shown, the reader's position would be strengthened.

DR. POLLITZER, in closing, said he would look upon glycosuria in the presence of xanthoma of the lids as a coincidence. He would regard the generalized form upon the hands and face as of the connective tissue variety, which disappears. He believed some toxemia was behind the sugar as a causative factor. Whether or not the process is inflammatory depends upon the definition of the term upon which pathologists in no wise agree. In the Cohnheim sense it is not clinically nor pathologically an inflammation. It is connective tissue proliferation. To this all will agree. The diabetic form differs from the tuberoso form, as Dr. Morrow claims, but the processes are similar.

DR. Shepherd's case, in which nodules of xanthoma disappeared promptly upon the removal of biliary calculi, is of much interest.

DR. WELCH, the President of the Congress, visited the Section, and in a brief address spoke of the great opportunities presented to the dermatologist for the study of general pathological conditions. Not only is the opportunity for securing material abundant, but the skin is so directly exposed to external injury, infection and to various stimuli that the inflammatory reactions can be observed clinically as well as histologically at every stage. He was pleased to observe that such excellent opportunities were not being wasted; and general pathology could confidently look to this department of science for most promising results in the future.

CONTRIBUTIONS TO THE ETIOLOGY OF CONGENITAL ICHTHYOSIS

was the title of the next paper, read by DR. J. M. WINFIELD, of Brooklyn.

In a case described there was absence of the thyroid gland and the presence of inflammatory changes in the derma suggestive of micro-organisms and such bodies were found in the lymph spaces. A bacterial irritation is capable of producing a seborrheal dermatitis, and the thyroid may have an inhibitory effect; and when the latter is absent it might account for the development of the ichthyotic changes. The mother after having three normal labors, bearing healthy infants, had two succeeding pregnancies which were attended with nervous shocks and excitement which resulted in the birth of ichthyotic children.

DR. HARTZELL thought it hardly possible that the theory of maternal impressions can apply to these cases, but the presence of micrococci must be regarded as accidental. The absence of thyroid was interesting but its exact etiological significance was difficult to state.

DR. GILCHRIST thought the arguments not very strong. Cocci of decomposition can be excluded because of the precautions taken in the examinations. If the thyroid alone is removed in the case of dogs without the para-thyroid gland being taken away at the same time, the same results do not follow as when

this is done. This fact might have a bearing on the case.

DR. BOWEN said such instances confirmed his opinion that two different processes have been described; one a keratoma, the other due to retention of the epitrachial membrane enveloping the child. The term keratosis was preferable to ichthyosis.

HEREDITARY AND CONTINUOUS SHEDDING OF THE FINGER-NAILS

was the next paper, in which DR. D. N. MONTGOMERY, of San Francisco, reported a clinical instance attended with the presence of albumin. In the shedding of nails in ataxia it is the toe-nails which are affected. In diabetes shedding is rare, though mentioned in the books.

In no case known to the reader has shedding been so continuous as in his own case now reported. The patient's mother and a maternal uncle had been similarly affected.

DR. JOHNSTON said, in discussing the paper, that there might be a granular degeneration in the matrix layer of the nail-bed.

DR. WHITE asked if there was trophic change in the hair, or if other members of the patient's family were thus affected. He referred to a photograph which he had exhibited, showing such combined trophic changes which had run through three generations.

DR. KLOTZ asked as to the condition of the teeth.

DR. MONTGOMERY said, in closing, that the theory of degeneration would not apply, since the nails were apparently healthy, being clear and transparent and were shed unchanged. The teeth and hair were good. While the mother and a maternal uncle had the same affection, the father's nails had been "crumbly," it was said.

DR. LUSTGARTEN suggested an analogy to epidermolysis bullosa, in which shedding of the nails occurs.

SYMMETRICAL ATROPHY OF THE SKIN

was the next paper, by DR. J. A. FORDYCE, of New York.

The case upon which it was based concerned a woman of forty years. Colored drawings were shown to illustrate the lesions and locations. These consisted of scaly patches followed by bullae upon the knees, ankle, foot and elbows. The general surface shows atrophic thinning. The first pathological change noted is capillary dilatation. The duration had been more lengthy in the cases hitherto reported than in this. It was thought to be allied to lupus erythematosus. There were evidences of vaso-motor disturbances but no organic affection of the nervous system could be detected.

DR. KLOTZ spoke of an instance which seemed to have a rheumatic origin.

DR. HYDE had never seen a similar case. Some of the appearances surely suggest lupus erythematosus.

DR. GILCHRIST said it had not been accepted by pathologists that lymphocytes leave the vessels. He thought idiopathic atrophy a good term for the affection.

DR. BRONSON thought it fair to surmise that this was an instance of the rare condition previously described. It differed in several particulars from the case described by himself, being more diffuse. He thought there might be a central spinal affection.

DR. DUHRING said he would regard the three or four cases of atrophic disease now described as identical. There are other diseases in which atrophy prevails but is preceded by inflammatory signs, as, for example, in striae atrophicæ and morphea. One case showing inflammatory symptoms at a given stage does not throw it out of the group. Later on, the inflammatory symptoms will probably all disappear. In classifying it the affection must be placed with the atrophies.

THIRD DAY.

SOME CASES OF FEIGNED ERUPTION

were reported in a paper read by DR. F. J. SHEPHERD, of Montreal.

Peculiar bullous, excoriated, ulcerated and gangrenous lesions were described, and photographs shown to illustrate cases not capable of classification under any of the recognized dermatoses. Some looked as though they might have been produced by burning the surface.

One case reported presented areas of dry gangrene upon the hands and forearms. After careful bandaging no more lesions appeared. The reader thought they had been produced by some heated disc of metal. In another, acid was thought the agent employed to cause lesions on the cheeks. Lesions upon the feet of a gangrenous nature in another case looked like those produced by a hot-water bottle in patients who were unconscious. The absence of motive should not preclude the diagnosis of feigned eruption.

DR. DUHRING thought we must have proof that an eruption is artificial before we can call it so. He had seen few instances of feigned eruption, and had proved that some so-called had been neurotic in origin.

DR. GRINDON spoke of artificial eruptions — not feigned, but produced by design.

DR. ALLEN spoke of the accidental effects of hot-water bottles.

DR. BRONSON spoke of a possible morbid susceptibility of the part; and he thought the reduced condition of the patient had much to do with the severity of the traumatism in hot-water-bag burns, for example. Similar lesions may not be due to design.

DR. WHITE said, in answer to Dr. Duhring, that circumstantial evidence should be admitted just as much as in a murder case. It would rarely occur that the patient could be detected in the act of inflicting personal injury. He referred to an instance of ulcerative dermatitis about the region of the mouth, evidently due to some application to remove hair, still no direct proof could be obtained.

DR. SHEPHERD said, in closing, that "eruptions probably feigned" would have been a better title for his paper.

(To be continued.)

INSANITY IN PRUSSIA is reported to be increasing so rapidly that the asylums are entirely inadequate to accommodate the large number of patients requiring treatment. In 1871 the total number of lunatics in Prussia was 55,063, in 1880 it had risen to 66,345, while in 1896 it had gone up to 82,850. The growth of insanity is more marked among men than among women. Of 100,000 Prussian males there are 278 insane, and of a like number of women, 243.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 21, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

LOWELL INSTITUTE LECTURES BY PROFESSORS DARWIN AND FOSTER.

THE simultaneous presence in Boston of two distinguished professors of the University of Cambridge, each speaking with the highest authority on his own special subject, is an event of no common interest in the educational history of Boston.

Prof. Geo. H. Darwin, a son of the great expounder of the theory of evolution in the organic world, himself a mathematician of the highest rank, is setting forth in a course of Lowell Lectures the theory of tidal movements, and drawing therefrom conclusions of the greatest importance in cosmical mechanics. Although this subject requires for its investigation the most refined methods of mathematical analysis, the results are presented in language free from technicalities and not requiring for its comprehension the special training of the physicist.

His colleague, Prof. Michael Foster, also speaking from the Lowell platform, is discussing a subject of more special interest to the members of the medical profession. "Some Features of Brain-Work" are presented by this well-known English physiologist in a course of six lectures, beginning October 18th. From the brief summary printed on the tickets, as well as from the success of the opening lecture, it is evident that the physiology of the nervous system in its unity as well as its complexity, as revealed by modern research, is to be sketched by a master hand.

Professor Foster requires no introduction to those members of the medical profession who have obtained their medical education within twenty years. In his text-book, published for the first time in 1877, the advanced student and the original investigator found not a collection of isolated and often conflicting statements, but a logical and careful presentation of evidence, with wise suggestions as to the direction in which truth was to be sought in those fields where investigations had yielded only uncertain results. In its successive editions the work has kept pace with the advance of physiology, and its author has shown us how in physiology,

as in other sciences, the "solid nucleus of acquired truth year by year grows larger at the expense of its envelope or zone of strife where truth and error mingle in conflict."

Professor Foster began his career as a physiologist in 1867, as lecturer on practical physiology in University College, London. In 1869 he was appointed professor in the same institution. In 1870 he became Prælector in Physiology at Trinity College, Cambridge, and in 1883 was appointed first professor of physiology in the University of Cambridge. Since 1881 he has held the position of Secretary of the Royal Society, and in this capacity has exerted a strong influence upon the development of science in England. He took a prominent part in the deliberations of the International Congress of 1896, in which it was decided that, beginning with the year 1900, a card catalogue of the scientific literature of the world shall be published under the auspices of the Royal Society, and when this great undertaking shall be inaugurated the result will be largely due to the energy and sagacity of Michael Foster.

Our profession is indeed to be congratulated on the opportunity afforded them by the Lowell Institute of meeting men so instrumental in determining the progress of contemporary science as Professors Darwin and Foster.

THE HEREDITY OF ACQUIRED CHARACTERISTICS.

THE theory of Weismann that acquired characteristics are not transmitted by heredity has not found favor with the medical profession. Apart from all speculations about body plasma, which is *individual* and modifiable, and germ plasma, which is *racial* and not modifiable—speculations which cannot be said to have a very substantial basis—the question to the medical man resolves itself into this: whether acquired peculiarities and morbid conditions are handed down to offspring. The physician who sees instances of congenital syphilis—one of the parents having been syphilitic—and congenital tuberculosis, neurasthenia, etc., derived from one or both parents who had acquired the morbidity, is likely to hold to the opposite of Weismann's contention. That certain nervous affections (as hysteria) acquired by the parent under circumstances of shock, great mental strain, etc., may be transmitted to one or more children is also a matter of frequent observation; finding its counterpart in experiments of Brown-Séquard, whereby guinea-pigs were rendered epileptic and transmitted to their young their epilepsy after certain injuries of the "epileptogenous zone."

Cesare Lombroso takes up the subject of the transmission of acquired characteristics in a late number of the *Forum*.¹ He remarks that the question is of the utmost importance not only in explaining the origin of zoölogical modifications in different species, but also in aiding us to decide whether we can profit

organically, so to speak, by the actions of our fathers, that is, whether the labor of the part can be accumulated and transformed into labor that may be called organic, or whether such labor must be wholly lost.

He alludes to the vast number of facts on record to prove that physical characteristics artificially acquired have been hereditarily transmitted. The biological history of the camel makes it wellnigh certain that the hump, which, as in the analogous tumors on porters' backs is only a collection of fat around a slight protuberance of the vertebrae, is a physical modification produced by burden-bearing, the wild llamas, ancestors of the camel, having absolutely no hump, while this hump is atrophied in the racing camel. The callosities of the knees and breasts, which arise in the camel from continual kneeling to receive its load, are acquired like the callosities of the human body, and though wanting in the camel's wild brethren, they are perfectly apparent in the young camel before he has begun to work.

Among the many examples of acquired psychical characteristics which the writer adduces is the following: Civilized man has acquired in the cerebral cortex—in a fold of the parietal lobe—the psychical centre of reading, which in certain maladies (in thrombosis and apoplexy) is paralyzed, causing the reading power to disappear. Now this centre has positively been acquired within historic time; it is certainly not found in men yet savage. The same may be said of the speech centre,—the third left frontal convolution,—since everything goes to prove that the first man had no language, just as the new-born child has no language, and the Hottentots and Weddahs have but very imperfect ones. The organ tends to become more and more differentiated in our modern civilization.

The above considerations, though fatal, in so far as they contain scientific fact, to Weismann's doctrine, that acquired faculties, etc., are not transmitted to offspring, will not to some readers carry the conviction which attends the demonstration in individual instances of the direct transmission of acquired characteristics. Weismann contends that influences which affect the somatic cells do not correspondingly affect the reproductive cells so that the modification or defect is entailed to progeny. But, going back to physical changes, does not the fact of hereditary syphilis prove such transmission? Here, apparently, is an external agent, the virus of syphilis, which has profoundly modified both germ cells and somatic cells in the parent and in the offspring. May not a thousand influences, of various orders, produce a similar effect? The syphilitic father cannot hope that in accordance with the Weismann doctrine, his unborn progeny may escape the malefic infection. The true doctrine of heredity lends no support to this view. That there is a direct transmission of moral as well as physical traits has been of common observation from antiquity.

"Scilicet expectas ut tradat mater honestos
Atque alios mores quam quos habet?"²

¹ Forum, October, 1897.

² Juvenal, Sat. vi, 239.

The doctrine of Weismann, lately so strongly assaulted by Herbert Spencer in the *Contemporary Review*, is so contrary to both physiological and pathological facts that we believe that it will be eventually abandoned by its author, as it is being generally discarded by scientific men everywhere.

The maternal influences affecting offspring are very subtle; a bad organic habit of the one may irretrievably blight the post-natal life of the other. Dr. Frank B. Earle recently reported a notable instance of the kind before the Chicago Medical Society. In the preceding December he attended at the birth of a ten-pound girl, whose mother, a morphinist, seemed specially solicitous regarding her babe. Inquiry revealed the fact that three children had died soon after birth, the first in two and a half days, and the third in four days. In this case, on the third day the child became sleepless, pale and prostrate; five minutes later died. The mother had taken eight to fourteen grains of morphine daily, commencing soon after marriage.⁸

Physiologists have observed that previous pregnancies have an influence upon offspring. Dr. Austin Flint remarks that this is well known to breeders of animals. "If pure-blooded mares or bitches have been once covered by an inferior male, in subsequent fecundations the young are likely to partake of the character of the first male, even if they be afterward bred with males of unimpeachable pedigree. What the mechanism of the influence of the first conception is it is impossible to say, but the fact is incontestable. The same influence is observed in the human subject,"⁴ Fookes of Fairfield, Wiltshire, England, has given instances of the same kind known to himself. Herbert Spencer, from a review of these and other facts with a like bearing, concludes that: "We must take it as a demonstrated fact that during gestation traits of constitution inherited from the father produce effects upon the constitution of the mother; and that these communicated effects are transmitted by her to subsequent offspring." "We are thus supplied with an absolute disproof of Weismann's doctrine that the reproductive cells are independent of and uninfluenced by the somatic cells; and there disappears absolutely the alleged obstacle to the transmission of acquired characters."⁵

MEDICAL NOTES.

UNIVERSITY OF TEXAS. — Dr. William S. Carter, demonstrator of physiology in the University of Pennsylvania, has been elected professor of physiology in the University of Texas.

TYPHUS FEVER AT SAN FRANCISCO. — A case of typhus fever was recently discovered at St. Luke's Hospital in San Francisco. The patient, a man aged twenty-three years, was removed to the pesthouse.

END OF THE SMALL-POX IN MONTREAL. — The health authorities of Montreal have declared that the small epidemic of small-pox, from which the city has suffered for some time, is now over, there having been no cases there for upwards of three weeks.

THE LIBRARY OF SIR MORELL MACKENZIE has been advertised for sale in a London auction room. Besides a large number of general works there are many authorities on his specialty. Among his own contributions to medical literature there are many copies of his "Growths in the Larynx" and "The Laryngoscope," both published in 1871, also of "Leprosy of the Air-Passages."

RULE MADE THAT MEDICAL SCHOOLS MUST TEACH IN ENGLISH. — We learn from the *Journal of the American Medical Association* that the quarterly meeting of the State Board of Health was held at the Great Northern Hotel, Chicago, October 5th. A resolution was adopted that after May, 1901, no school of medicine or midwifery would be recognized unless its instruction was given in the English language. A number of schools of midwifery in Chicago will be affected. After May 1, 1898, no candidate for license to practise medicine in the State will be examined unless he gives documentary evidence of a preliminary or basis education equivalent to that of a high school course.

YELLOW FEVER IN THE SOUTH. — The yellow-fever situation has not improved; and October 18th the number of deaths in New Orleans had reached 100. Somewhat less than 900 cases have been reported to the New Orleans Board of Health since the beginning of the epidemic in September. The disease has appeared at Baton Rouge, and at Montgomery, Ala. Dr. Guiteras is reported by the *Boston Herald* to have given his opinion with regard to the source of the epidemic as follows: "The source of this epidemic is, as usual, the island of Cuba. At least 90 per cent. of the cases of yellow fever imported into the United States from which epidemics have resulted have been introduced from Cuba. The last great epidemic was that of 1878. It cost this country many thousands of lives and \$200,000,000. That amount, added to what the present affliction will entail, would be more than enough to buy the whole island. A complete system of sanitation in Havana is the only means to prevent importing the disease into the United States. American methods of sanitation could eradicate it from Havana. The attitude of the Spanish government with regard to the malady has always been that of criminal indifference." With Havana as a constant and unregenerate source of infection, and the shotgun quarantine as a familiar and favorite means of protection, we do not seem to have made much real progress since the great epidemic of 1878. Fortunately November and colder weather are not far off. The general public at the South does not demand from the health-officer and the doctor the truth, but what it wants to hear; under these conditions there are doubtless those who have not the courage to tell the truth.

⁴ New York Independent, October 7, 1897 (article by Dr. J. B. Mattison).

⁵ Flint's Text-Book of Human Physiology, American Edition, 1888, p. 797.

⁶ Contemporary Review, May, 1893.

Trade from Northern cities to the South has of late been seriously interrupted.

THE MISSING LINK.—The party of scientists and antiquarians who were exploring the Rocky Mountains in the spring of the year 2000, mounted on their new '00 model bikes, suddenly heard a loud cry of triumph from the lips of Professor Rubbertire of the Smithsonian Institution, who was some distance ahead. Hastening forward, they found the professor standing by the side of the moldering remains of a wagon. In front of the decaying fragments lay the petrified remains of four extinct animals. "See!" said the professor, pointing to the animal to the right, nearest the wagon. "We have found the missing link between that noble machine, the bicycle, and the animal kingdom at last."—"What is it?" asked the excited group.—"That, gentlemen," said the professor, "is undoubtedly the fossil remains of a wheel horse."—*Detroit Free Press.*

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, October 20, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 48, scarlet fever 26, measles 3, typhoid fever 23.

THE STRAFFORD DISTRICT (N. H.) MEDICAL SOCIETY.—This medical society held its ninetyeth annual meeting at Dover, N. H., October 13th. Dr. A. C. Heffenger, of Portsmouth, was elected president.

A PROTEST OF THE NEWPORT SANITARY PROTECTIVE ASSOCIATION.—The Newport (R. I.) Sanitary Protective Association, at a recent meeting, protested against the manner in which the Newport City Council had filled the place of city physician recently made vacant by the death of the late Dr. Turner, alleging that the present incumbent is the only one of the twenty-five practitioners of medicine in Newport who has not a diploma from a reputable and legally chartered medical college. His legal status as a practitioner is alleged to depend upon a statement from the late Dr. Turner that he was engaged in the practice of the medical profession in Rhode Island prior to January 1, 1892.

NEW YORK.

YELLOW FEVER AND COMMERCE.—Three steamship lines running out of New York for New Orleans and Galveston are practically tied up, trade through the ports of the Gulf of Mexico having been paralyzed on account of yellow fever. It was the action on October 10th of the health authorities at interior ports supplied from the cities named, in prohibiting the reception or through transit of freight handled in those places, that caused the check to Southern commerce. The evil effects of the suspension are felt in heavy loss to shippers, carriers, merchants and customers; the loss of wages to sailors and longshoremen; higher prices to consumers for necessities, at points in the extreme South and the Southwest, and

temporary famine in such goods as are ordinarily shipped from the port of New York. It would be a loss to allow freight to accumulate at the quarantined ports, as country towns would refuse to take it at any future time.

LORD KELVIN'S VISIT TO COLUMBIA UNIVERSITY.—Lord Kelvin, the electrical expert and one of the most eminent of living English scientists, who arrived in this country in August last to attend the meeting at Toronto of the British Association for the Advancement of Science, sailed from New York on October 16th. A couple of days before his departure he paid a visit to the new buildings of Columbia University, through which he was escorted by Dr. Chandler and several members of the Faculty. He paid particular attention to the inspection of the scientific laboratories, which, although the apparatus is not yet complete, afforded him much interest, and expressed himself as greatly pleased with all the latest American appliances. "It is amazing," he said, "how much you Americans can accomplish in two short years. These buildings are marvellously constructed considering this brief space of time. I envy you that library. It is a strange, but true, fact that in Great Britain we could never have found such liberality for such a purpose."

THE COST OF INDISCRIMINATE CHARITY.—The Commissioners of the Department of Public Charities on October 11th adopted the report of Superintendent of the Poor, Bauer, on the result of his investigation of unworthy cases of charity. On March 26, 1896, the President of the Board directed Mr. Bauer to make a census of the different private institutions which were paid to take care of the city's poor, sick and needy. This was done in conformity with the rule established by the State Board of Charities, in accordance with the revised constitution of 1894. The report shows that \$1,313,491 has been expended on unworthy people, and the result will be a great saving to the city in the future. There were 26,561 individuals being supported. Of these Mr. Bauer has approved 13,276, and disapproved 13,285.

GYMNASIUMS IN THE PUBLIC PARKS.—A well-attended and enthusiastic meeting was recently held at Terrace Garden in favor of free gymnasiums in the public parks and the opening of more play-grounds for the children of the city. The practical spirit of the meeting was shown by its adoption of the plan of beginning the good work with a gymnasium in the new East River Park, and attention was called to the success which Boston has met with in establishing such gymnasiums, as pointing the way to a similar success in New York. All that is needed is official action in response to the strong and unquestioned popular demand.

A CASE OF QUADRUPLETS.—The wife of a motorman on the Troy City Railroad has had four children at a birth. Two of them were males and two females, and the average weight of the infants was six and one-

half pounds. The family resides at Albion, a suburb of Troy, and there are four other children, the oldest being a girl of sixteen and the youngest a boy of five.

DEATH OF DR. BLOODGOOD.—Dr. William E. Bloodgood, a retired physician, died at his residence in West 89th Street, New York, on October 10th, in the seventy-fifth year of his age. He was a graduate of the Medical Department of the University of the City of New York, and for a number of years was a prominent practitioner. Later, however, he gave up the profession and engaged in business.

DEATH OF DR. JAMES P. DALY.—Dr. James P. Daly, a Democratic candidate for coroner in the Borough of the Bronx at the approaching Greater New York election, died of apoplexy on October 15th; and the immediate cause of the attack is said to have been mental strain and overwork in the campaign. On the night preceding his death he addressed two political meetings, and the first symptom of illness appeared just after the conclusion of his second speech. Dr. Daly was a graduate of Bellevue Hospital Medical College, in the year 1886, and was a well-known practitioner in the annexed district of the city.

Miscellaneous.

MEDICAL RESPONSIBILITY FOR THE ABUSE OF MEDICAL CHARITY.

It is perhaps well to remind the medical profession that at least a part of the blame for the abuse of medical charity, the results of which are so disastrous alike to the public and the profession, is to be placed on their own shoulders. At a discussion on the subject held at the recent meeting of the New York State Medical Association, Mr. J. Harsen Rhoades made some pertinent remarks on this subject:

"I shall criticise your own profession rather sharply," he said, "but I wish it understood that I do it in the kindest spirit. You must recall that we laymen connected with charitable institutions must rely upon your recommendation largely in passing upon applicants to the medical staff. Most charitable institutions are too poor to establish a bureau to examine applicants.

"But the first great cause of the abuse of medical charity, I take it, is in the great multiplication of medical works of this character. There are too many hospitals, too many dispensaries, too many private institutions. Their number should be reduced. Dispensaries should not be allowed to accumulate.

"The next great cause of the abuses complained of is in the ambition of young medical men to attach themselves to medical charities already in existence, or to found new ones in connection with church charities, or independently, upon which they hope to build reputation for themselves, and out of which they expect individually to earn a living and establish a practice.

"Then there is the difficulty of determining who are poor and who are able to pay and the natural repugnance to close inquiry through fear of driving away those really entitled to aid, for it is the honest poor who suffer in silence and who possess an honorable pride which prevents a disclosure of their true condition. In this connection must be mentioned the secret willingness of many young practitioners to conceal facts which come to their knowledge

showing a patient's ability to pay, in the hope of securing such patient for private practice.

"The remedy seems to me, to lie in careful selection of young physicians for service in medical institutions and hospitals, and business principles applied in the profession; to dismiss or compel the resignation of all men appointed who prove careless, incompetent or self-seeking; and this is not now, nor has it ever been done, on the part of the medical profession.

"There is also need of the passage of a law which shall compel all charitable institutions of every kind to establish a clearance bureau, which can be easily done in connection with the Charity Organization Society, each sharing in the expense of maintaining such bureau and in proportion to the number of patients recorded against each. Such a law should compel all institutions to send weekly a list of all patients applying for relief, with their residences and all known facts. These names should be filed, tabulated and investigated by the clearance bureau, and the result sent to each institution. It is my honest belief that such a bureau, once in operation, would disclose an amount of fraud on the part of thousands and tens of thousands who now receive alms or help of various kinds that would be appalling."

THE PRICE OF BREAD IN ITALY, AND THE HEALTH OF THE POOR.

A CORRESPONDENT of the *Lancet*, writing from Rome, makes the following statement:

The dearness of bread has been agitating nearly every commune, from the Alps to Etna, bringing the proletariat and the poor into sharp collision with the bakers, throwing the bakers themselves "upon strike," and sending deputations from both interests—the consumers and producers—to magistrates, members of Parliament, and even the Prime Minister, the Marquess Di Rudini himself, without, however, as far as one can see, eliciting any hope of a way out of the imbroglio. Local circumstances intervened to modify the situation, which may roughly be described as this: the poor cannot afford to pay 40 centimes (4d.) for the *pagnotta* (loaf), and the bakers cannot afford to sell it at less unless the flour is supplied them at a figure below that at which the *dazio consumo*, or octroi duty, maintains it. What is occurring here occurs, plus "local color," all throughout the kingdom. The Syndic invites the *Associazione dei Negozianti Fornai* (Association of Shop-keeping, as distinguished from *lavoranti*, journeyman bakers), to offer bread for sale at 40 centimes for the better quality and 38 or 35 centimes for the inferior. The *Associazione* replies, with flour at its present price, *Non possumus*. A threat on the part of the Communal Administration to impose *prezzi coercitivi* (compulsory prices) on the bakers is met with a defiant, "You had better try." At Venice the journeyman bakers go out on strike, and the *Municipio* (town council) orders two hundred *quintali* (hundredweight) of bread from Milan to keep the "Queen of the Adriatic" from starving; but the strikers have the grim satisfaction of seeing the said municipality constrained to sell it at 30 centimes the kilogramme, a significant commentary on the threat of *prezzi coercitivi*. Meanwhile the lack of bread is bringing other ailments to the front, and the potato—in Italy a rather slighted esculent—is having its turn of popularity. Edibles of even humbler sustaining power are also invoked, with the result that "fungi" of more than suspected quality are multiplying the cases, already all too frequent, of "mushroom poisoning."

The crisis through which Italy is now passing is very grave. Malnutrition is one of the many curses of her laboring poor: prolific of stunted stature, impaired muscular power, and generally of the diseased developments fraught with evil augury of her future. Vainly do her medical philanthropists, like Dr. Angelo Celli, professor of hygiene in our medical school, tax their ingenuity to invent a more nutritive dough than that employed by the baking interest.

The crushing *dazio consumo* lays its paralyzing finger on all such efforts, and forces men like Professor Celli and forty more of the same profession to court a seat in Parliament in order to cut at the root of the evil by fiscal amelioration and financial reform. Some twenty of these medical candidates were returned for as many constituencies at the general election in March last, and nearly all of them sit on the Extreme Left. And *quid mirum?* They are medical philanthropists first and political legislators afterwards; and their first thought is to raise the submerged masses from the slough of insanitation, with its attendant following of disease, crime and anarchic conspiracy, and place them on the footing promised them when "Italy, one and independent," was substituted for "Italy, a geographical expression."

A few figures will show what fearful abuses philanthropists like Dr. Celli and Dr. Colajanni are laboring to remove, and agitating the public and Parliament to consider. In Naples alone malnutrition in 1873 caused 131 deaths, *con vizi di conformazione congeniti* (congenitally abnormal conformation); and in 1896 the number had risen to 240. In the same city, in 1873, there were 1,216 deaths from tuberculosis in its various forms, and in 1896 they rose to 1,812. Increase of population does not explain this evil increment, which, as Dr. Colajanni remarks, is *graduale costante*. The Di Rudini Government will soon have to face a reassembled Parliament; and one of its first duties will be to consider the ill-nourished, badly-housed, hygienically-neglected poor—to leave the “Dark Continent” to take care of itself and to brighten that still darker region around it—the true “Italia Irredenta”—which seethes, suffers and succumbs.

THE AMERICAN JOURNAL OF PHYSIOLOGY.

THE number of investigations in physiology and its allied sciences now made in this country is grown so large that the present means of publication are no longer sufficient. Physiologists can no longer print in foreign countries, often in foreign languages, or in general medical journals, without stunting a growth, which, unchecked, will come to be a gratification to every American, and a wholesome influence in American medicine. To meet the needs of investigators in physiology, physiological chemistry, physiological pharmacology, bio-chemistry and certain other branches of biology, a special journal will be published, the first number appearing in January, 1898. The *American Journal of Physiology*, as the new publication will be called, will contain in each volume about five hundred pages, divided into parts or numbers, to be issued whenever material is received. It is expected that not more than one volume a year will be printed. The *Journal* will be edited by H. P. Bowditch, M.D., Boston; R. H. Chittenden, M.D., New Haven; W. H. Howell, M.D., Baltimore; F. S. Lee, M.D., New York; Jacques Loeb, M.D., Chicago; W. P. Lombard, M.D., Ann Arbor; and W. T. Porter, M.D., Boston.

It is not to be supposed that a journal devoted solely to the publication of original researches in physiology will ever do more than pay for its paper and printing, and it is probable that some years must pass before the new enterprise will cease to be a financial burden on a small number of investigators. Yet the need of such a publication is undoubted. The aid of all friends of learning is asked until the journal shall be established on a self-supporting basis. The subscription price, which is five dollars per volume, should be sent to W. T. Porter, M.D., 688 Boylston Street, Boston, Mass.

METEOROLOGICAL RECORD

For the week ending October 9th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Baro-	Thermom-		Relative		Direction		Velocity		We'th'r.		Rainfall in inches.

Deaths reported 2,357; under five years of age 737; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping cough, erysipelas, and fevers) 314, consumption 280, acute lung diseases 237, diarrheal diseases 115, diphtheria and croup 97, typhoid fever 45, whooping-cough 31, scarlet fever, cerebro-spinal meningitis and malarial fever 7 each, erysipelas 2.

From whooping-cough Baltimore 11, New York 9, Philadelphia 4, St. Louis 3, Cincinnati 2, Pittsburg and Providence 1 each. From measles New York 2. From scarlet fever New York 3, Providence 2, Philadelphia and Baltimore 1 each. From cerebro-spinal meningitis New York and Worcester 3 each, Washington 1. From malarial fever Philadelphia, St. Louis and Nashville 2 each, Boston 1. From erysipelas New York 2.

In the thirty-three greater towns of England and Wales with

an estimated population of 10,992,524, for the week ending October 2d, the death-rate was 16.8. Deaths reported 3,538, diarrhea 229, diphtheria 67, fever 61, measles 60, scarlet fever 51, whooping-cough 46.

The death-rates ranged from 11.7 in Cardiff to 23.7 in Liverpool; Birmingham 17.1, Bradford 17.1, Croydon 12.0, Gateshead 20.1, Huddersfield 13.9, Leeds 18.2, Leicester 13.3, London 15.3, Manchester 21.3, Newcastle-on-Tyne 21.6, Nottingham 16.6, Portsmouth 12.9, Salford 20.3, Sunderland 17.6, Swansea 13.0.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 9, 1897, TO OCTOBER 15, 1897.

The leave of absence granted CAPTAIN ASHTON B. HEYL, assistant surgeon, Fort Riley, Kan., is extended two months.

Leave of absence for one month is granted FIRST-LIEUT. JAMES S. WILSON, assistant surgeon, Camp Eagle Pass, Tex.

Leave of absence for one month is granted CAPTAIN W. E. PURVIANCE, assistant surgeon, Fort Columbus, N. Y.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE TWO WEEKS ENDING OCTOBER 16, 1897.

J. C. WISE, medical inspector; F. A. HESLER, passed assistant surgeon; R. K. SMITH, assistant surgeon, detached from the "Philadelphia" and ordered to the "Baltimore."

N. L. BATES, medical director, detached from the Museum of Hygiene and ordered to duty as chief of the Bureau of Medicine and Surgery.

J. R. TRYON, medical director, detached from the Bureau of Medicine and Surgery and ordered to New York as general inspector of United States naval hospitals.

H. J. BABIN, medical inspector, ordered as president of the Naval Examining Board, New York, October 9th.

C. H. WHITE, medical director, detached as president of Naval Examining Board, New York, October 9th, and ordered to Washington in charge of Naval Museum of Hygiene.

J. C. PRYOR, assistant surgeon, detached from the Naval Hospital, Mare Island, and ordered to the "Adams."

A. FARENHOLT, assistant surgeon, detached from the "Vermont" and ordered to New York Navy Yard.

C. G. HERNDON, surgeon, ordered on temporary duty at the Naval Museum of Hygiene.

W. B. GROVE, assistant surgeon, detached from Naval Laboratory, New York, and ordered to Mare Island Hospital.

C. P. BAGG, passed assistant surgeon, detached from the "Marion" and ordered to the "Adams."

M. K. JOHNSON, assistant surgeon, detached from the "New York" and ordered to duty with the "Vicksburg."

R. SPEAR, assistant surgeon, detached from the Naval Laboratory, New York, and ordered to the "New York."

C. BIDDLE, surgeon, detached from Marine Hospital, San Francisco, ordered to Washington in charge of patient, then report at the Navy Department.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE TWO WEEKS ENDING OCTOBER 9, 1897.

KALLOCH, P. C., surgeon. To proceed to McComb, Miss., for special duty. October 2, 1897.

WASDIN, EUGENE, passed assistant surgeon. Relieved from duty at Ocean Springs, Miss., and directed to proceed to New Orleans, La., and report to Surgeon H. E. CARTER for duty. October 4, 1897.

MAGRUDER, G. M., passed assistant surgeon. To proceed to Sabine Pass, Tex., for special duty. October 3, 1897. To proceed to Houston, Tex., and await orders. October 9, 1897.

COBB, J. O., passed assistant surgeon. Relieved from duty at Cairo, Ill., and directed to proceed to Jackson, Miss. September 27, 1897. To proceed to Fontainebleau, Miss., for duty. October 9, 1897.

GEDDINGS, H. D., passed assistant surgeon. To proceed to New Orleans, La., and report to Surgeon H. E. CARTER for duty. September 27, 1897.

CLARK, TALIAFERO, assistant surgeon. To proceed to Cairo, Ill., for temporary duty. October 2, 1897. Granted leave of absence for two days. October 4, 1897.

PROMOTION.

PARKER C. KALLOCH, passed assistant surgeon, commissioned as surgeon, September 22, 1897.

CASUALTY.

W. D. BRATTON, passed assistant surgeon, died at Sabine Pass, Tex., October 2, 1897, of injuries contracted in line of duty.

RESIGNATION.

DR. GUSTAV LIEBMANN, has resigned his position in the College of Physicians and Surgeons of Boston as Professor of Diseases of the Digestive Organs.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about one hundred and eighty dollars, will be made on July 14, 1898, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered.

Essays intended for competition may be upon any subject in medicine, but cannot have been published, and must be received by the Secretary of the College on or before May 1, 1898.

Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author.

It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned upon application within three months after the award.

The Alvarenga Prize for 1897 has been awarded to Dr. Joseph Collins, of New York, for his essay entitled: "Aphasia."

THOMAS R. NEILSON, *Secretary*.

RECENT DEATHS.

SURGEON-GENERAL NEWTON L. BATES, of the U. S. Navy, died at Washington, on October 18th. He was appointed surgeon-general about two weeks ago, to succeed Surgeon-General Tryon, and was obliged, on account of the illness which finally resulted in his death, to take the oath of office in bed. He entered the navy from New York State in June, 1861, and prior to his appointment as surgeon-general was a medical director with the relative rank of captain, and was on duty at the Naval Museum of Hygiene in Washington.

WILLIAM D. BRATTON, Passed Assistant Surgeon, died, at Sabine Pass, Texas, on the 2d instant, under peculiarly distressing circumstances.

In the pressing need of medical officers for active work during the present yellow-fever epidemic in the South, Passed Assistant Surgeon Bratton, though an invalid, and, therefore, on waiting orders, promptly volunteered his services to meet the emergency, and the tender was accepted in the spirit in which it was made. He was ordered to Sabine Pass to assume charge of service matters relating to the quarantine service at that port, where he arrived and reported himself on duty the 28th ultimo. On the 1st instant he had been superintending the disinfection of a vessel; and returning to the ship to reassure himself upon the work done, he fell through a ventilating hole, striking his head on an iron knee, producing concussion of the brain. He remained undiscovered for several hours, and when found was unconscious, and remained so until death occurred, eighteen hours after the unfortunate accident.

William Du Bose Bratton was born in Fairfield County, South Carolina, June 23, 1860, the son of General John Bratton, of Winnsboro, in that State. He was graduated at the Medical College of South Carolina, March 1, 1884, and for the year following was house-surgeon at the Charleston City Hospital.

He was commissioned as assistant surgeon April 1, 1885. He was commissioned a passed assistant surgeon April 2, 1888, and again assigned to duty as medical officer on the revenue cutter *Bear* for service in Alaskan waters. In May, 1889, he was ordered to duty in command of the Service at Portland, Ore., where he remained two years, and was then assigned to duty at Chicago, Ill. In 1893, he was placed in command of the Service at Buffalo, N. Y., where he remained till January 9, 1894.

In the fall of 1893, he first became aware of a condition of his health which gradually disclosed a tuberculous character, and after the Bureau had been officially informed of it, he was sent to Wilmington, N. C., for its favorable climate, where he remained several months, doing meanwhile temporary service at Delaware Breakwater Quarantine, but later he was placed on "waiting orders" (January 1, 1895), taking up his residence in Arizona, and finally in New Mexico, to obtain the advantages of the southwestern arid region. After a two years' residence there, he reported, in March, 1897, his gradual return to a state of health, which justified him in asking for an early restoration to active duty; but further delay was advised in order that he might have the benefit of a longer residence and, if possible, a permanent cure.

During the period of "waiting orders," he became much interested in the climatic treatment of consumptives, and wrote several reports on the arid region of the Southwest as the best locality for such work, recommending the establishment of a sanitarium in that section for the treatment of patients of this Service suffering from the disease.

Original Articles.

ON THE BACTERIOLOGICAL EXAMINATION OF THE STOOLS IN TYPHOID FEVER, AND ITS VALUE IN DIAGNOSIS.¹

BY MARK W. RICHARDSON, M.D., BOSTON,
From the Laboratory of the Massachusetts General Hospital, Boston, Mass.

THE bacteriological history of typhoid fever begins properly with the year 1880. Previous to that time, though much work had been done upon this disease by Klein, Klebs, Birsch-Hirschfeld and others, and that, too, with the object of finding, if possible, an organism specific for the malady, yet little had been accomplished to clear up satisfactorily the etiology of typhoid fever.

In those days, of course, the science of bacteriology was in its infancy, and the search for a disease-germ was carried on under conditions infinitely more difficult, and with methods immeasurably more crude than those now employed. Practically, all our elaborate culture methods were still to be discovered, and we find the first bacteriological work of Klein, Klebs, Birsch-Hirschfeld, Eberth and Koch upon typhoid confined almost entirely to the search for micro-organisms in stained sections of typhoidal tissues.

Up to 1880, then, nothing conclusive had been determined. Elaborate studies of intestinal lesions, mesenteric glands, the spleen, kidneys and liver had demonstrated often, to be sure, the presence in these organs of various bacteria, mainly cocci, but the results of these investigations had been very inconstant, and did not allow the formation of any conclusions as to the relation of the organisms to the disease process.

In 1880, Eberth,² in a most painstaking series of observations, demonstrated in the organs of typhoid cadavers with great constancy the presence of collections of short, stout bacilli, with rounded ends. These observations were confirmed almost immediately by Koch,³ who, working entirely independently, had arrived at very similar conclusions.

The next advance was made by Gaffky,⁴ who first obtained the new organism in pure culture, and subjected its characteristics to thorough study.

The claims of Eberth, Koch and Gaffky, that in this new bacillus the cause of typhoid fever had been found, have been borne out by the experience of the past fifteen years, but not without opposition; for, with the improvement in bacteriological technique, several other organisms very similar to the typhoid have been discovered, to identify which a considerable number of differential tests have been found to be essential. Of these pseudo-typhoid organisms the bacillus coli communis has been the most troublesome; indeed, Lösenner⁵ states that, up to 1894, no less than 689 methods had been suggested for the differentiation of the typhoid and the colon bacillus alone. Lösenner concludes that an organism, in order to be proved the typhoid bacillus, must satisfy the following ten conditions:

1. The organism must show, without liquefaction, a characteristic growth upon gelatin.
2. Must vary in size, and have marked motility.

3. Must have a large number of flagella (10-12-15).
4. Must decolorize by Gram's method of staining.
5. Must form no gas when grown in a medium containing grape, milk or muscle sugar.
6. Must cause no coagulation of sterilized milk.
7. Must produce no indol when grown in an albuminous medium.

8. Must produce, in neutral milk-serum, an acid reaction, never exceeding three per cent. of a deci-normal sodic-hydrate solution.

9. Must grow upon one-half of a potato in the same manner as a known typhoid organism on the other half.

10. Must show no growth upon Maassen's normal solution with addition of glycerin.

Then to these ten essentials we add perhaps the most important:

11. The organism must show the specific typhoid reaction when treated with typhoid serum.

Furthermore, Proskauer and Capaldi, in a recent publication, recommend the use of two test solutions devised by them.⁶ In Solution No. 1 the typhoid bacillus does not grow at all, whereas the colon bacillus not only grows but also produces an intense acid reaction. In Solution No. 2 both organisms grow; but, in this case, it is the typhoid which produces the acid reaction. I have applied this test to 16 typhoid and six colon cultures, and my results have been uniformly satisfactory.

Although the bacillus coli communis, with its many varieties, has been the chief bacterium to necessitate these differential tests, its manner of reaction to the various media differs markedly from that of the typhoid bacillus. It would not seem difficult, therefore, to consider them organisms differing utterly in nature. It is only when we study other bacilli of the same group, such as the bacillus fecalis alkaligenes, or the mouse-typhoid bacillus, organisms which combine, in most striking manner, the characteristics of both coli and typhoid, that we begin to doubt whether, after all, the typhoid bacillus is anything more than a modification of the colon bacillus, which, under favoring conditions, has changed its nature, and acquired a much increased virulence.

This problem has been solved, I think, by R. Pfeiffer's discovery⁷ of the specific serum reaction which takes place when a fluid culture of the typhoid bacillus is treated with the serum of a person sick with typhoid, or with the serum of an animal made artificially immune to typhoid. In this reaction, as is well known, the typhoid bacilli, which are ordinarily perfectly discrete, motile organisms, lose their motility, and become clumped together into larger or smaller aggregations. Under certain fixed conditions, it has been found that no organism but that of typhoid fever will react to typhoid serum. It would seem, therefore, that this specific reaction of the organism to the products of its own growth were sufficient evidence that it is a bacterium *sui generis*.

Having demonstrated the new organism with great constancy in the tissues of persons dead of typhoid fever, bacteriologists next turned their attention to the problem of isolating the typhoid bacillus from the fluids and excretions of the living body.

Gaffky⁸ made cultivations from typhoid stools upon ordinary gelatin, but the speedy liquefaction of his

medium by the other organisms present caused his experiments to fail.

In 1885, A. Pfeiffer⁹ announced that, by the use of an agar medium, he had been able to isolate from typhoid dejections a bacillus identical with that of Eberth.

In the same year, Simonds¹⁰ cultivated upon gelatin the typhoid bacillus from the stool of a patient at the sixteenth day of the disease.

In 1889, Karlinski¹¹ examined the stools of 21 typhoid patients with positive results in all. The organisms never appeared before the ninth day, and in three cases the bacilli were obtained first upon the 21st day.

In 1890, Karlinski¹² said that out of 44 cases, in which the symptoms had been those of typhoid, and in which the typhoid bacilli had been found in the stools, the organisms were found also in the urine in 21. Further, the presence of the bacilli in the urine was always associated with albuminuria. Karlinski succeeded in cultivating bacilli from the urine in one case as early as the third day of the disease.

In 1891, Karlinski¹³ reported several atypical typhoid cases in which, at autopsy, no intestinal lesions were found, but in which typhoid bacilli had been cultivated from the blood. Furthermore, typhoid bacilli were found in the blood, rose-spots and spleen, by Seitz,¹⁴ Klein,¹⁵ Neuhaus¹⁶ and Rutimayer.¹⁷

From the observations of the above-mentioned writers, and especially from those of Karlinski, it would appear that the detection of typhoid bacilli in any suspected material must be a very simple matter. When, however, we learn that, in proving their cultures, these observers used practically but three differential methods: the hanging drop, the growth on gelatin, and especially the absence of visible growth upon potato, we see that the value of their work can be but very little; for we now know that these few test-conditions are fully satisfied by several other organisms. It is, therefore, more than probable that the organisms isolated by Karlinski and others were, in the great majority of cases, not typhoid bacilli at all, but other bacilli of the same group, probably varieties of the colon bacillus.

In the examination of stools for typhoid bacilli the chief difficulties have arisen from the presence of other varieties of bacteria. These have been a disturbing element, first, because their colonies often resembled markedly those of typhoid, and, secondly, because they, in their growth, often liquefied the gelatin before the typhoid colonies got a chance to grow. This latter difficulty could be obviated, to be sure, by the use of an agar medium, but the procedure still remained largely one of chance, and it was necessary to pick up and verify many colonies at random in the hope that one or more would prove to be typhoid.

It was essential, therefore, to devise some medium upon which either typhoid bacilli alone would grow, or upon which they could be distinguished easily even in the presence of other organisms. To this end Chantemesse and Widal¹⁸ added to ordinary gelatin carbolic acid in the strength of one-fourth per cent. By this

means the growth of bacteria other than typhoid was said to be inhibited.

Thoinot¹⁹ applied the same principle by adding to 500 c. c. of suspected water 20 drops of carbolic acid. In this case, also, all bacteria except typhoid were said to be inhibited in their growth.

Holz²⁰ could confirm only partially the results of Chantemesse, Widal and Thoinot. Holz conceived the idea of combining the advantages of potato and gelatin in one medium. His gelatin was made up with a watery extract of potato, and given such an acidity that 10 c. c. would be neutralized by from 2.4 to 3.2 c. c. of a deci-normal sodic-hydrate solution. This acidity in itself prevented the growth of a number of organisms, and this inhibitory power was still further increased by the addition of .03 per cent. of carbolic acid. Upon this medium the growth of the typhoid bacilli was said to be characteristic, the colonies, and especially those upon the surface, being easily distinguished as small, clear, oval and transparent.

Although the potato gelatin of Holz marked a distinct advance in differential media, it seems to have found comparatively little favor, for, in 1895, we find Wathelet²¹ still working with ordinary gelatin. Wathelet examined about six stools in each of 12 typhoid cases; 600 different colonies were picked up and verified, and only 10 of these proved to be typhoid. These 10 colonies came from four cases, and never in any case were the specific organisms found in more than in one stool. How Wathelet proved his cultures is not stated. It is probable, however, that modern differential methods were used, an assumption which would explain, in large part, the discrepancy between his results and those of writers in the eighties, when misplaced confidence in potato cultures undoubtedly caused most serious mistakes.

It seems clear, therefore, that, up to 1895, the bacteriological examination of the stools in typhoid fever could have had but little real value as a diagnostic procedure.

In 1895, the subject was again taken up, and this time by Elsner.²² Elsner considered the potato gelatin of Holz the best medium devised up to that time. The appearance of the typhoid colonies was not always characteristic, however, especially when the carbolic acid was added.

Elsner, in his work, first experimented with infusions of hay, beets, straw and grass, but could not improve upon the potato extract. Then he made a long search for a substitute for carbolic acid. A great variety of substances were tried, such as naphthol, balsams, oils, alkaloids, glycogen, indol, scatol, urea, and many chemical salts and combinations. The substance finally hit upon was the iodide of potash in the strength of one per cent.

The formula for this medium, as given by Elsner, was very brief and somewhat unsatisfactory. I will, therefore, give it more in detail as carried out by myself.

1. (a) Pare carefully and cut into small pieces half a kilogramme of small potatoes. (Small potatoes are less acid and thus better for our purpose.) Or better, grate the potatoes to a fine pulp. (b) Add a litre of water and let stand twenty-four hours in a cool place. Or, instead, the mixture may be boiled for one and a

half hours. In the latter case, after boiling, make up to one litre the loss of water by evaporation.

2. Mash thoroughly, and strain through a fine cloth.

3. Boil with 10 per cent. or 15 per cent. gelatin.

4. Clear with egg.

5. Filter first through cotton, then through paper.

6. Test the acidity with deci-normal sodic-hydrate solution. If 10 c. c. are neutralized by from 1.5. to 2.5 c. c. of the sodic-hydrate solution, the medium is sufficiently correct as to acidity. If it takes more than 2.5 c. c. to neutralize 10 c. c. of the medium, then the acidity must be reduced by the addition of normal sodic-hydrate solution.

7. Add K. I., one per cent.: (a) to the medium as a whole, or (b) to the individual tubes as used. Use a solution of K. I. so made that one cubic centimetre is equivalent to one gramme of the salt.

Gelatin made up in this way gave, in most instances, satisfaction. Several times, however, for some reason still unknown, the medium failed to allow the typhoid bacilli to grow upon it. The fault probably lay in some variation in the potatoes used.

Upon this medium typhoid and colon-bacilli were practically the only organisms to grow. Rarely proteus and other forms were seen. Moreover, the growth of the typhoid and colon bacilli was perfectly characteristic. In twenty-four hours, at the room temperature, only colon colonies were visible, and these appeared as gray-brown, round, and coarsely granular. The typhoid colonies, on the other hand, appeared first after the lapse of forty-eight hours, and were characterized by their small size, pallor, translucency, and fine granulation. They were also described as resembling drops of dew.

Elsner experimented with 30 typhoid and colon cultures, and never failed to differentiate them easily. He also diluted the typhoid bacilli with water up to 1:8,000,000,000, and could still demonstrate their presence. Further, he examined the feces of 17 typhoid patients, with 15 positive results. Each organism was proved as to its identity by all modern methods, including Pfeiffer's serum test. In several cases the organisms were isolated as early as the seventh day, and, in one case, as late as the sixth week. Since the publication of Elsner's article his method has been used by a considerable number of other observers.

Brieger²³ examined the stools of 10 typhoid cases, all with positive results. He further observed that, as a case became afebrile, the bacilli disappeared largely from the stools. This was not always the case, however, for, in one instance upon the second, and in another upon the 38th day, of convalescence, the organisms were still present. In Brieger's opinion, if the bacilli persist, we should fear a relapse.

Lazarus²⁴ demonstrated repeatedly typhoid organisms in five cases examined between the first and third weeks. In one convalescent case the examination of the stools was positive 41 days after the temperature had reached the normal point.

Chantemesse²⁵ examined 13 cases, all with positive results. Eight cases were positive on the seventh day, one on the 26th day, the other four coming between these two dates.

Pollac²⁶ searched 62 stools in 20 cases. Bacilli

were found as early as the seventh day, and as late as the 30th day, also twice during relapse. In 30 normal stools no bacilli were found. One case was especially interesting and instructive, inasmuch as it came to autopsy and no typhoid lesions were found. Further investigation showed that the bacillus isolated had not been the typhoid bacillus at all, but the bacillus fecalis alkaligenes of Petruschky.²⁷ This organism resembles markedly that of typhoid, but it can now be easily differentiated by its failure to react to typhoid serum, as well as by its characteristic of producing an alkaline and not an acid reaction when grown in proper media.

Mills²⁸ examined one stool in each of seven cases, of which six were typical typhoids, while one simulated an appendicitis. Positive results were obtained in two cases—the so-called appendicitis upon the tenth day, and a typhoid late in the disease.

Courmont²⁹ investigated 9 typhoids and 11 other cases. Two typhoids gave positive results, the rest were negative. The number of stools examined in each case was not stated.

Finally, according to Remlinger and Schneider³⁰ typhoid bacilli were found by the Elsner method in the stools of 5 out of 10 non-typhoidal patients; in 9 out of 37 samples of well and spring water; and in 7 out of 13 samples of dust. The stools were those of (1) a case of leukemia with fever, (2) a case of miliary tuberculosis without intestinal symptoms, (3) a case of intestinal disturbance previous to an acute dysentery, (4) two cases of chronic malaria with no intestinal symptoms. In the case of the water and the dust, the organisms were found irrespective of the presence of a typhoid epidemic in the locality. These results are, of course, very remarkable. I think, however, until they are confirmed by other observers, they should be received with great reserve.

Although, at the time of its publication, the method of Elsner marked a great advance as a diagnostic procedure in typhoid fever, its value has been recently completely overshadowed by the specific serum reaction discovered by Pfeiffer and perfected by Widal.

My own investigations were undertaken primarily to test the practicability of the Elsner method as such. Later my object was to compare it with the serum test—to see whether there might not be cases characterized by no serum reaction, but in which bacilli could be demonstrated in the stools. Finally, I wished to test, if possible, the value of the assertions of Remlinger and Schneider as to the ubiquity of the typhoid bacillus.

Before enumerating my results I will state that the latter part of my experiments were carried out upon an agar medium devised by Capaldi.³¹

This medium is made up as follows:

Aq. dest.	1000.0
Witte's peptone	20.0
Gelatin	10.0
Mannit (or grape sugar)	10.0
Na. Cl.	5.0
Potassium chloride	5.0

Boil and filter. Add two per cent. agar. Make alkaline with 10 c. c. of a normal sodic-hydrate solution. Boil, filter and sterilize. In eighteen hours the typhoid colonies are seen as small, round, colorless

and transparent, in contrast to the larger, more opaque, brownish colon colonies. I have never had any difficulty in making up this medium, and my results with it have been at least as good as, if not superior to, those with the potato gelatin. Its advantages are:

1. Liquefaction is avoided.
2. Colonies are much larger, and thus more easily picked up. With the gelatin the typhoid colonies were often so small that it was impossible to make inoculations from them.

3. Plates are ready for examination in eighteen hours rather than in forty-eight or seventy-two hours.

The only disadvantage is that colonies of the bacillus pyocyaneus, or of the streptococcus, often resemble markedly those of typhoid. The only difference in procedure is that, with the agar the plates are first poured and hardened, the suspected material being spread upon their surface, whereas, with the gelatin the material and media are thoroughly mixed before the plates are poured. Although I have made use of two methods in my work, my results, for the sake of simplicity, will be considered together.

In the course of my investigations there were examined 109 stools in the cases of 49 individuals. Of these 49 cases, 13 were typical typhoids in the febrile stage, and in these 13 cases 55 stools were examined.

The isolation of the typhoid bacillus was accomplished in 10 out of the 13 febrile cases, in 19 out of the 55 stools. In one case the bacilli were found on what was said to be the fifth day; but the history was somewhat indefinite, and the disease was probably farther advanced. Two cases were positive on the 11th day. In the other seven cases the typhoid organisms were first discovered on the 12th, 20th, 23d, 27th, 28th, 29th and 36th days respectively. Seven out of the 10 cases were positive upon the first examination. How much sooner the organisms might have been found had the stools been received earlier it is, of course, impossible to say. In the three other positive febrile cases the bacilli were isolated only after several examinations on the 20th, 27th and 28th days.

In proving the typhoid cultures thus obtained the following methods were used:

1. Hanging drop, for size, shape and motility.
2. Growth on gelatin stab and slant.
3. Growth on bouillon.
4. Growth on sugar agar. No production of gas.
5. Growth on peptone solution. No production of indol.
6. Growth on potato. No visible growth.
7. Growth on litmus-milk. No coagulation. Very slight production of acidity.
8. Two test solutions of Capaldi and Proskauer.
9. Reaction to typhoid serum.

Of the negative febrile cases, three in number, one was unsatisfactory because the stools could be examined but once, and that on the sixth day of the disease. The other two cases were typical typhoids, and one went through a relapse as well. Although six stools in one case and eight in the other were searched, and that too, by both methods (Elsner and Capaldi), I was never able to isolate the typhoid bacillus.

All these 13 cases gave well-marked serum reactions at least two days before the organisms could be recovered from the stools. We see, therefore, that, as far as this series of cases goes, the serum test proved itself, in all ways, much superior as a diagnostic aid. There have been a number of cases reported,

however, such as those of Biggs and Park,⁸² Breuer,⁸³ Thoinot,⁸⁴ and Achard⁸⁵ in which the serum reaction did not come until very late in the disease — till convalescence began, or perhaps till a relapse occurred. In such cases it would seem as if a bacteriological examination of the stools would be of great value, for the appearance of the bacilli in the dejections of the second week is a quite common occurrence. In fact, Kolle⁸⁶ reports two cases which illustrate this point, in which the serum reaction was obtained first on the 16th and 17th days, but where the bacilli were cultivated on the 10th and 11th days.

To continue with my own cases: two stools in two cases of doubtful typhoid were examined with negative results. These two cases never presented any serum reaction, and were practically convalescent when investigated.

Twenty-three stools of 13 convalescent cases gave but one positive result, and that one day after the fever had disappeared. In one of these cases the search was kept up till the 24th day, but the results were all negative.

Seventeen stools of 17 non-typhoidal patients were all negative. Included in this series were cases of grippe, pneumonia, sepsis, meningitis, otitis media, endocarditis, gonorrheal rheumatism and neurasthenia.

Furthermore, the intestinal contents of 12 individuals were secured at autopsy and examined. This series of observations was undertaken in order that, in case of a positive result, there might be no doubt as to the diagnosis. The pathological examination in these cases showed them to be absolutely non-typhoidal in character, and bacteriological cultivation never revealed any typhoidal bacilli.

From the foregoing, it will be seen that the dejections of 29 non-typhoidal individuals showed no typhoid bacilli. Moreover, when we add to this number 47 similar stools examined by Pollac, Chantemesse and Courmont, we have a total of 76 with not a single positive result.

This experience is certainly very different from that of Remlinger and Schneider, who found specific bacilli in 50 per cent. of the non-typhoidal stools investigated. The only case supporting Remlinger and Schneider which I could find was one referred to by Chantemesse as occurring in a person whose occupation was that of caring for typhoid patients.

CONCLUSIONS.

1. The isolation of typhoid bacilli from the dejections of persons sick with typhoid fever is, in the great majority of cases, a practicable procedure.
2. With the appearance of convalescence the organisms disappear rapidly from the stools. They may persist, however, for several weeks. This fact is important as regards disinfection.
3. The value of the serum test is, in most instances, greater, by reason of its simplicity and its earlier appearance. In those cases, however, in which the specific blood changes necessary for the serum reaction do not appear till late in the disease, till convalescence or till the occurrence of a relapse — in such instances the bacteriological examination of the stools can be of great value.

4. The results of Remlinger and Schneider, who declare the typhoid bacillus to be a ubiquitous organism, could not be confirmed by the writer.

In closing, I wish to express my thanks to those physicians of Boston and vicinity who have, in so many ways, materially assisted me in my work. I am especially indebted in this regard to Dr. J. H. Wright, Director of the Pathological Laboratory at the Massachusetts General Hospital, and to Drs. Pegram and Low, house physicians at the Children's Hospital.

SOME CASES OF CYSTITIS.¹

BY EDGAR GARCEAU, M.D., BOSTON,

Surgeon to Out-Patients, Free Hospital for Women; Lecturer on Gynecology in Tufts Medical School.

IN general terms, the curable affections are those which are superficial in character, while those resisting treatment are the cases of long-standing cystitis in which the inflammation has involved the interstitial tissue and muscles. In the latter cases local treatment is often of little avail. At cystotomies undertaken for the cure of these cases one never fails to note a great increase in thickness of the bladder wall; it is apparent from this that injections and medicines taken internally must have very little curative effect since their action is exerted only upon the mucous membrane of the bladder. The only treatment thus far which gives relief and sometimes cures is cystotomy; but the disagreeable features of this operation are so marked that one hesitates before recommending it. In the superficial forms of inflammation the advantage given by the cystoscope is that the lesions can be treated locally and that the applications can be made directly and exclusively to the diseased areas leaving the rest of the bladder intact; much stronger stimulating applications can therefore be made, which in many instances excite a healthy regenerative action and so effect a rapid cure.

The various diseases of the bladder can therefore be treated intelligently and with an appreciation which sight only can give. Before the advent of the cystoscope it was customary to diagnose and treat as "cystitis" cases in which the cardinal symptoms of inflammation of the bladder were present, associated with the presence of pus in the urine. Necessarily no clinical attempt could be made to determine the extent and seat of the lesion. For instance, a case of nodular cystitis may give rise to exactly the same train of symptoms as a single solitary ulcer, or as a chronic interstitial cystitis; yet the treatment is radically different in each. This being the case, it seems justifiable to subject to cystoscopic examination women who have suffered from cystitis for an appreciable length of time, reserving for the classical treatment solely those cases of acute cystitis which are so readily and easily cured by simple means.

Lest it should be thought that a cystoscopic examination involves an excessive amount of suffering, it may be said here that this is not the case. With a No. 8 (millimetre) cystoscope and a good light the female bladder may be inspected with ease and satisfaction, all parts being brought under the eye and submitted to actual inspection. With this small-sized cystoscope previous dilation of the urethra,

really the most painful part of cystoscopic examinations, is quite unnecessary in the great majority of women. The examination, in the knee-chest posture, may be made practically painless if one or two crystals of pure cocaine are inserted in the meatus urinarius and left there a few moments before the cystoscope is introduced. The author has found this to be the best method of cocaineizing the meatus. But after the first examination, it will be possible to dispense with cocaineization, for the passage of the instrument causes no more pain than the passage of the female catheter.

Treatment of vesical lesions can be carried on through the small-sized cystoscope quite as well as through a larger one. The cases which follow have been selected with a view of demonstrating the necessity of cystoscopic examination.

CASE I. Nodular cystitis.

Mrs. H. A., a woman forty-seven years old, was seen April 1, 1897, for the first time. Her urinary symptoms began last September, and were sudden in their onset. She thinks she "caught cold." She passed urine very frequently, and had a good deal of tenesmus. This lasted three weeks, and then there was a respite for a while. She had another attack in December, and others at intervals until the time when first seen. Then she was urinating every few moments with much "needle-like" pain and great tenesmus. She got up five or six times a night. The general health under these circumstances was very poor and she had emaciated rapidly. There was a history of phthisis in two paternal uncles.

The cystoscope showed the following: Urethra and vesical neck somewhat redder than normal; bladder slightly redder than normal. A small patch of enlarged lymphoid nodules, circular in outline, one centimetre in diameter, slightly elevated above the surface, deep red in color, of velvety appearance, was seen in the left hemisphere, in the posterior wall, just above the trigonum. A similar smaller patch was seen in a corresponding situation in the right hemisphere. There was no enlargement of either kidney on external examination, and no other sign of renal involvement. Her previous childbirths had stretched the meatus urinarius so that it was quite patulous, and this patulous condition of the meatus made it probable that the infection was an ascending one rather than a descending one. Still, in order to ascertain the condition of the kidneys with reference to a possible purulent affection in one or both, especially as there was a phthisical history, the ureters were both catheterized. The urine drawn exhibited the following characteristics:

RIGHT URETER.—Nine and one-half cubic centimetres in seven minutes. Urea, 1.13 per cent. Bloody (trauma). Faintly acid. One-eighth to one-quarter per cent. of albumin. Much sediment; chiefly blood; many small caudate cells; small and medium round cells, free and in clumps; rather numerous hyaline and granular casts, some with fat adherent; few leucocytes, free and in an occasional small clump.

LEFT URETER.—Eight cubic centimetres in seven minutes. Urea, 1.39 per cent. Normal color. Very acid. Trace of albumin. Much sediment; many small caudate epithelia; round epithelia; occasional leucocyte; rarely brown granular cast of large diameter; occasional hyaline casts, some with fat adherent.

BLADDER URINE.—Urea, 2.52 per cent. Normal color. Very acid. Trace of albumin. Considerable sediment: normal blood; squamous epithelia; many hyaline casts, rarely one with renal epithelium adherent, some with fat adherent; few renal epithelia; some pus; numerous round epithelia, free and in clumps.

This examination showed that there was no suppurating process going on in the kidneys. The casts

¹ Read, by invitation, before the Obstetrical Society of Boston, April 20, 1897.

and other elements were accounted for by passive congestion due to a cardiac complication.

As an experiment, the treatment of this case was entirely local in nature, no drugs having been given internally. The treatment began by touching the patches with nitrate of silver powder collected on the end of a wet probe; care was taken to make the application accurately so as not to touch the surrounding mucous membrane. The relief was immediate and marked. She at once urinated only six or seven times a day, and got up twice at night. Three days later the patches were burned with a fine galvano-cautery needle. Two days after this she was urinating four times a day and did not have to get up at night at all. The patches exhibited a healthy aspect and were diminishing in size. Six months later she was still well.

This case is a typical one of the class of cases first described by Alexander² and by him called "nodular cystitis." In this form of cystitis the inflammation affects the lymphoid nodules, which are found in the majority of healthy bladders. These nodules are of small size, but when inflamed they become enlarged and rise above the surface of the mucous membrane of the bladder. In the inflamed state, the nodule attains the size of a sago grain. The nodules have a disposition to become inflamed in certain localities, and this leads to the formation of patches which are made up of many nodules closely packed together: occasionally they may be seen scattered about here and there individually inflamed. Alexander thinks that this form of cystitis possesses no characteristic features which entitle it to be classed as a special disease etiologically considered; he thinks it simply an infection of the lymphoid nodules of the bladder, as distinct from a diffuse inflammation affecting the mucous membrane as a whole.

CASE II. Acute cystitis, ulceration of the urethra; Bartholinitis; cystotomy.

Mrs. X was forty-eight years old. For many years she had suffered from a fibroid which had been kept in check by appropriate treatment. Her urinary symptoms began four weeks before she was first seen by the author. The usual symptoms of cystitis were present: frequent painful micturition and tenesmus. At one period she was urinating every few minutes, but lately the pain attending the act of micturition was so intense that the desire to urinate was controlled so that she could limit the number of urinations to once in two hours; when she did urinate, however, she suffered intense agony in the urethra, and the pain lasted an hour afterwards. The right vulvo-vaginal gland was swollen, and pus could be squeezed from it.

There was a question of periurethral abscess, inasmuch as a considerable amount of pus could be squeezed from the urethra at one time. The meatus was patulous. In order to determine the nature of the lesion ether was given. The urethra was much thickened, but through the cystoscope no opening of an abscess could be detected with a probe; there was, furthermore, no undue thickening at any one point. But at the vesical orifice were three very small ulcers with grayish bases; and there was another one a little lower down towards the meatus, larger in extent. They were all cauterized with a hot probe. The bladder was intensely injected, and presented the appearance of active inflammation of a mucous membrane. No ulcerations were seen in the bladder.

The day after this treatment she was still suffering great pain on urination, and an attempt was made to make an application of iodoform powder to the irritable ulcers; but it was so painful that repetition of the procedure was impossible. Inasmuch as she was exhausted by her long agony, and inasmuch as local treatment was impracticable, it seemed best to drain the bladder by cystotomy, in order to prevent the urine from passing over the irritable ulcers. This was done accordingly. Complete relief followed. The vulvo-vaginal gland was dissected out and removed at the same sitting, and the urethral ulcers cured. When the inflammation has subsided under the influence of hot boracic acid douches and internal diluents the artificial opening will be closed.

This case takes its interest from the fact that cystotomy was done for an acute affection. Urethral ulcers can generally be treated satisfactorily by local applications. In this case the general inflammation of the bladder and urethra was so severe that the symptoms strictly referable to the ulcers were thereby greatly intensified. The patient was a sensible woman, not neurotic in the least, and capable of enduring great pain without much complaint. Her sufferings were extreme, and demanded relief imperatively.

CASE III. Cystitis, with superficial ulceration.

Mrs. H. was a woman twenty-nine years old, who had had three children and three miscarriages. Since the last child was born, four years before examination, she had been ill. At that time a catheter had been used for retention, and she had had more or less trouble with the bladder ever since. There were periods of repose during which she suffered but little; but at other times she was greatly annoyed. When first seen, last September, she was obliged to urinate every ten or fifteen minutes; and so great was the vesical irritability that if she could not urinate when she wished to there was incontinence. At the menstrual periods her sufferings were aggravated.

Pelvic examination disclosed a large, tender right ovary, and a similar condition on the left side. The uterus was large and heavy, and there was a discharge exuding from the os. The cervix was lacerated. The cystoscope showed a bladder which was slightly injected throughout, and here and there were several small yellow areas, about half a centimetre in diameter, which appeared to be superficial ulcers. The vesical neck, trigonum and urethra were all very much injected.

The treatment began by touching the yellow spots with a ten-per-cent. solution of nitrate of silver, and likewise painting the trigonum, vesical neck and urethra with the same solution. Appropriate treatment for the pelvic condition was also instituted. The topical applications were repeated three or four times at intervals of a few days, and at the end of that time there was marked improvement. She was then urinating every hour only, and got up twice at night; the incontinence happened only twice a day. The next time the cystoscope was introduced the ulcerations were all touched with solid nitrate of silver stick. This treatment cured her, for when she was seen the next time, seven days later, she announced that she was well. Urination was only four times a day, and she slept all night without waking. There was no pain and no incontinence.

In December she was operated on at the Free Hospital for Women, and had the cervix repaired and a

² Journal of Cutaneous and Genito-Urinary Diseases, July, 1893.

cureting done. When seen again, the latter part of January, she was quite comfortable. The urination was normal, and her pelvic symptoms were much relieved.

The special feature of this case was the rapid relief given by cauterizing the ulcers.

CASE IV. Ulceration of the vesical neck.

Mrs. C. was first seen in August, 1896. She gave a history of some previous bladder trouble, and there was also a history of a miscarriage which had caused a double salpingo-ovaritis; but the latter affection was in the chronic stage and gave little trouble. The principal complaint was with the bladder. She was urinating every little while night and day; and the pain both during and after the act was most severe. It was described as knife-like, or needle-like. This description suggested either fissure of the neck of the bladder or ulcer of the urethra.

On cystoscopic examination a smaller ulcer pointing towards the right ureter was found just inside the sphincter vesicæ, about one and a half centimetres long and two millimetres wide. It had a zone of hyperemia around it. The trigonum was injected, and the rest of the bladder was also somewhat red. The ulcer was touched with pure nitrate of silver. Thirteen days later she reported herself well. There was no pain on micturition; she urinated only two or three times a day, and not at all at night. This relief seemed so rapid that it excited some suspicion as to whether the patient's veracity could be relied upon; but this suspicion was set aside when she came again two weeks later with a history of further trouble with the bladder. She said she had experienced so much relief from the last application that she wished to have it repeated. This was done, and she had no further trouble. Seen three weeks afterwards, she reported herself well.

CASE V. Secondary carcinoma of the trigonum.

Mrs. H., a woman forty-five years old, had been troubled more or less for several months with frequency of micturition. But her principal trouble, cancer of the uterus and vagina, had given rise to such severe symptoms that the vesical irritation was not thought much of. At the operation for removal of the cancerous growth — cureting — a cystoscopic examination was made in order to cauterize, if it seemed desirable to do so. The bladder-wall was markedly infiltrated on the side of the vagina. Through the cystoscope several irregular nodules were seen projecting up on the surface of the trigonum, and at the summit of the most prominent of these nodules was a small red spot where the disease was just breaking through. The rest of the bladder was normal in appearance. The red spots were touched with nitrate of silver. Three weeks later she was having no trouble with the bladder. Urination was every six hours, including the night. The relief will doubtless be only temporary.

THE COST OF YELLOW FEVER. — According to the *New York Herald*, it is estimated that the loss to business men in New Orleans alone will amount to \$25,000,000, while the losses in other directions and the cost of maintaining the quarantine will run the total up to \$38,000,000. Most of this loss is the result of the unreasonable excitement of the neighboring towns and villages, which have shut off all supplies from New Orleans, paralyzing business in that city.

THE DIAGNOSIS OF SOME COMMON INJURIES IN THE SHOULDER REGION.¹

BY AGNES C. VIETOR, M.D., BOSTON, MASS.,

Acting House-Surgeon, New England Hospital, Boston; Late Instructor in Physical Diagnosis and Surgery, Woman's Medical College of the New York Infirmary, etc.

(Concluded from No. 17, p. 415.)

THIS brings us to the last of the anatomical elements outside the shoulder-joint — the periarticular cellular tissue. This is merely the loose connective tissue which fills in the interstices which would otherwise be left among the more highly specialized tissues already enumerated.

Gibney¹⁸ describes a primary inflammation of this tissue which he prefers to call a periarthrititis.

Naurede mentions a primary inflammation which he more exactly calls *periarthritic cellulitis*: its pathology is similar to that of cellulitis in other regions, and it yields similar symptoms, only modified according to the neighboring tissues.

Duplay¹⁴ quotes the conclusions of Jarjavay as to the occurrence of subacromio-deltoid bursitis. He says he has several times verified the accuracy of Jarjavay's description, but he claims that all of Jarjavay's cases were acute, succeeding immediately or almost immediately to the trauma. He then calls attention to what he claims is a chronic type, which he names *scapulo-humeral periarthrititis*. He was able to hold an autopsy on one of his patients, but an analysis of the findings which he reports, shows that in this case, which the author calls one of periarthrititis,¹⁶ the lesions demonstrated may be considered as five: (1) chronic subacromio-deltoid bursitis and subdeltoid cellulitis, with obliteration of bursa and formation of connective-tissue adhesions between the deltoid and humerus; (2) chronic inflammation of the capsule (most marked in lower portion) leading to thickening; (3) periarticular cellulitis, internal to the joint, leading to the formation of fibrous connective tissue; (4) congestion of ulnar and internal cutaneous nerves; (5) atrophy of deltoid. Examination of the biceps is not reported, although the author explains the semiflexion of the forearm and the pain in the elbow and coracoid process by assuming the existence of adhesions between the deltoid and biceps. Examination of the circumflex nerve is omitted, also, though in his further remarks on the case, the author assumes that the pain upon pressure is due to a neuritis of the circumflex nerve, the result of compression and traction exercised by the adhesions.

It must also be noted that the injury was not a simple traumatism of the shoulder but was complicated by a dislocation of the humerus, and it is impossible to say how many of the pathological findings above reported were due to this dislocation.¹⁶

¹ Read before the Section on General Surgery of the New York Academy of Medicine, May 11, 1896.

¹⁸ Gibney: *Periarthritis*, New York Medical Journal, 1880, xxxi, p. 449.

¹⁴ Duplay: *De la Péri-arthrite Scapulo-humérale et des Raideurs Qui en sont la Conséquence*, Arch. Gen. de Méd., 1872, 6 s., xx, 2.

¹⁶ "This periarthrititis, localized more particularly in the subacromio-bursa and in the subdeltoid cellular tissue, determines thickening and induration of the cellular tissue and of the walls of the bursa, the formation of adhesions and of fibrous bands which impede or completely prevent the gliding of the upper extremity of the humerus beneath the coraco-acromial vault and the under surface of the deltoid."

¹⁶ It is interesting to note the condition of the subacromio-deltoid bursa in seven cases of extensive injury of the shoulder-joint, with probable dislocation of the humerus, reported in detail by John Gregory Smith (London Medical Gazette, 1834, xiv). In three of these cases, it is simply noted that the bursa communicated with the joint; in three, the bursa was said to be enlarged and its walls thickened; in one, no mention of bursa was made.

Nevertheless, most stress is rightfully laid by the author upon this case because it is the only one in which an autopsy could be held. He reports five cases of simple contusion followed by similar symptoms, and these he claims are also due to a similar pathological condition, having for origin a traumatic inflammation of the periarticular tissues.

It seems a just criticism to object to the use of the term *peri-arthritis* for a group of lesions several of which it is already possible to diagnosticate separately; and, again, to suggest that the question is not only as to the existence of a peri-arthritis in a case complicated by a dislocation, but whether it is correct to attribute the same pathological changes to similar symptoms when the provoking causes are radically different in extent and complexity, and when such symptoms might result from other lesions.¹⁷ Even in this first case of Duplay's, it is legitimate to ask whether the thickening of the capsule may not have been an important factor in the ankylosis, and whether passive motion, gymnastics, cataplasms, douches and massage may not have been effectual in stretching a thickened capsule as well as in stretching and rupturing adhesions.¹⁸

It cannot be regarded, then, as a fully established fact that, in the absence of a predisposing cause, slight injuries will provoke a connective-tissue inflammation of such magnitude. It is, however, very well established that slight injuries will provoke a synovitis (and this may expend its chief activity on the surroundings of the joint, according to Barwell) or a nerve lesion.

One is forcibly impressed, on reading Duplay's paper, with the fact that the study is incomplete in that while symptoms are present pointing directly to nerve involvement, no examination of the nerves is made, and that while a muscular atrophy is mentioned in every case, no data are given for determining whether this is a simple or a degenerative atrophy.

Desplats¹⁹ was not satisfied that a scapulo-humeral "peri-arthritis" would account for the muscular atrophy in Duplay's cases, especially in regions as remote from the articulation as the forearm and hand. He reports two cases which he diagnosticates as "rheumatism," in which the shoulder symptoms were similar to those described by Duplay under the heading of "peri-arthritis." In both, Desplats found sensitiveness of the brachial plexus, and in one of them the deltoid showed a diminished response to the faradic current, while the posterior deltoid gave no response whatever to it. He also noted trophic changes in the skin and subcutaneous areolar tissue.

With this review of the possibilities, I wish to point out that the symptoms which our patient presents do not correspond exactly with those of any of the groups above mentioned, but that they do present points of similarity with all of them; and, further, that it is not necessary to assume the existence, as a separate lesion, of any of these inflammatory conditions.

We note first of all that the symptoms of a traumatism of the brachial plexus are clear and unmistakable. Nothing else will satisfactorily account for the nerve and muscle symptoms already enumerated, when taken in connection with the history. I would suggest that the shoulder symptoms are the result of a trophic change due to injury of the circumflex nerve which already shows such marked disturbance in its sensory and motor branches. It will be remembered that the circumflex nerve supplies not only the shoulder-joint but also all the tissues from the joint outward to, and including, the integument.

It is well recognized that structural changes in the joints occur in association with, or as a consequence of, nerve lesions. Charcot²⁰ describes them in cerebral, spinal and peripheral lesions.

S. Weir Mitchell²¹ calls attention to the fact that his father, Prof. J. K. Mitchell, in 1831, described joint lesions following spinal injuries, occurring below the point of spinal affection. He continues: "Of all the various forms of mischief wrought by nerve wounds, most intractable and disabling are curious inflammatory states of joints to which we were the first to call attention." Again, he says, "It is quite clear that injuries of the spine, diseases of this organ and of the brain, and wounds or any form of lesion of nerves are capable of developing in the joints inflammatory conditions, usually subacute, and which so precisely resemble rheumatic arthritis in their symptoms and results that no clinical skill can discriminate between the two.

Bowlby²² says: "It has been my fortune to observe for some years past, and to keep constantly under my notice, a large number of cases of nerve injury of most varied kinds, yet in none of them have I seen any joint affections so extremely acute and painful as those described by S. Weir Mitchell. On the other hand, I think that arthritic lesions of a less severe and more chronic kind are amongst the most common results of nerve injury."

The apparent discrepancy existing between the joint symptoms described by Weir Mitchell and by Bowlby is removed when one recalls the various articular and periarticular tissues already enumerated, and remembers that all these tissues are usually supplied by the same nerve; and, further, that the trophic manifestations of a nerve lesion vary greatly—as to the particular tissue affected, the area of distribution, the kind of trophic change and its extent. Thus, it would seem from Weir Mitchell's description that in the cases to which he there refers, the synovial membrane was affected in its cavity as well as in its deeper, more extra-articular relations. Bowlby's description, on the contrary, gives no suggestion of synovial change, unless it might be in the direction of atrophy. The case I have reported, this evening, and others to which I will refer later, seem to have points in common with both Weir Mitchell's and Bowlby's, but to correspond with neither. However, they are, I believe, only different manifestations of the same cause.

I have not found cases like mine described, but the literature is full of expressions which would indicate that every writer on the subject of joint or nerve lesions has frequently met with analogous con-

¹⁷ As Richet says (*Des Opérations Applicables aux Ankyloses*, Paris, 1850): "Ankylosis is not a disease; it is an organic condition which follows a disease; it is stamped with no peculiar character when the affection which has given birth to it has disappeared. It is only a vicious cicatrice."

¹⁸ Berne (*Traitement des Péri-arthrites Scapulo-humérales par le Massage Méthodique*, L'Union Méd., 1897, 3 s., xlv, p. 151) recapitulates Duplay's article and reports eight similar cases, with results which closely parallel those of Duplay. Berne, however, used only massage, saying, "Massage is the most potent and the surest means of cure applicable to peri-arthritis."

ditions in other localities — and perhaps in the same, also.²³

Unfortunately, so few post-mortem examinations have been made that we are as yet unable to decide what are the joint changes occurring in these cases. Some periarticular changes usually accompany intra-articular lesions of any duration, but extra-articular changes may exist alone and may exactly simulate intra-articular disabilities. While Duplay's case can not be regarded as conclusive because of its complication with dislocation and because of the non-examination of the circumflex nerve and its distribution, nevertheless, one must remember its many points of correspondence with the case of this patient and of others which I shall report; and while the partial ankylosis could be explained by contraction of the capsule,²⁴ or other trophic joint changes in the area of distribution of the circumflex nerve, hindering the descent of the humeral head, it would be equally well explained by trophic changes in the area of distribution of the circumflex nerve to the subdeltoid areolar and periarticular tissues, hindering the ascent of the greater tuberosity.

The diagnosis, then, which I offer in this case is a traumatism of the brachial plexus, leading to muscular paralysis and atrophy; and partial ankylosis of the shoulder, from trophic changes in the area of distribution of the circumflex nerve, somewhere within the abduction curve. Reasoning from analogy of reported cases and from anatomy, these changes would probably be located either in the capsule (lower part?) or in the subacromio-deltoid areolar tissue — although intra-articular changes cannot be excluded.

The next is a more interesting patient in that she came under observation the day after the accident, and in that various manifestations of the nerve lesion appeared one after the other.

CASE III. A woman, fifty-six years old, housewife. Yesterday, she fell down several steps; catching at the knob of the door, as she began to fall, she says she "stretched" the left arm. She complains of pain when moving the humerus in any way, as well as of spontaneous pain in the shoulder-joint and in the deltoid and biceps region.

Physical Examination. — Comparison made with right side. Left arm hangs at the side, flexed at the elbow, patient supporting the forearm with the right hand. She says she supports it because it hurts more at the shoulder when she lets it hang. Deltoid region looks flatter, the muscular markings being obliterated. Ecchymoses over the deltoid, a little above the insertion, and over the lower third of the biceps. Tenderness on pressure above and in front of the shoulder-joint and over the ecchymoses. Deltoid feels softer than normal. No anesthesia, but the patient seems a little slow in localizing impressions. No atrophy is perceptible.

Nicalse: Injuries and Diseases of Nerves: Ashurst, International Encyclopedia of Surgery, New York, 1882, vol. iii, p. 570.

²⁴ In this connection, Dr. Mary Putnam Jacobi says: "It is well known that during the trophic lesions of inflammation, the elements of tissues revert to their youthful, embryonic form. Further, that a special characteristic of young fibrous tissue is its marked tendency to retract, as is shown in the fibrous tissue of cicatrices. We may be therefore justified in asking whether the trophic lesion of the fibrous capsule, due to the injury of its nerve, may not determine a reversion towards an earlier, more youthful structure, characterized by the special aptitude for retraction which we observe in cicatricial tissue."²⁵

Voluntary Movements. — Abduction only to about 10° (about the degree of abduction possessed by the supraspinatus). No flexion or anterior abduction; slight extension and slight posterior abduction; rotation is incomplete, both internal and external.

Flexion of forearm on arm only a little beyond a right angle. The forearm is held flexed simply to permit the patient to support the arm and so ease the pain in the shoulder (due to contusion and to the weight of the arm now unsupported by the relaxed deltoid). It is readily extended when the arm is supported so that no movement is communicated to the shoulder, and so that the arm does not drag upon it. When the forearm is extended, pronation and supination are incomplete; when it is flexed and the elbow supported, pronation and supination are complete.

Passive Movements. — All can be made, but with great difficulty on account of the pain referred especially to the shoulder-joint.

Electrical Examination. — Same responses on both sides to both faradic and galvanic currents in nerves and muscles; on the left side, the passage of the current through the nerves and the contraction of the muscles around the shoulder-joint caused pain.

To economize space, the further course of the case will be briefly summarized here.²⁵

Beginning with a paralysis of the deltoid, which was complete when seen the next day, a partial paralysis of the biceps, and a pronounced contusion which obscured the field of activity of the shoulder muscles, it seemed that the extent of the mischief was declared. Under absolute rest in a shoulder splint, the case ran a promising course. As the effects of the contusion passed off, the power of the deltoid appeared to return. Remembering what Weir Mitchell says of contusion of nerves — "in graver lesions, sensory and motor power are usually both lost at first, even if a bullet merely grazes the nerve, so that at the outset one can not know whether the nerve is divided or merely stunned. It is common to see function return after what seemed a serious loss" — I hoped to see the improvement continue. But the appearance of changed quantitative and qualitative electrical reaction in nerve and muscle and commencing atrophy of the muscle showed the damage to the circumflex nerve was intrinsic.

As the effects of the contusion still further decreased, movements in general became freer, pain lessened till it became a negative matter, lingering strongest in the region of the contusion over the lower third of the biceps but remaining somewhat in the deltoid region and the shoulder, especially when movement was attempted.

At the end of the third week, the biceps showed increased weakness and some decided electrical change in both nerve and muscle reactions, and commencing atrophy of the muscle. Next, a quantitative change appeared in the triceps and supinator.

Then, suddenly, at about the end of the fourth week after the injury, all the former symptoms returned but many times more pronounced. The pain was intense, making the patient groan aloud, and it extended over the whole scapula and arm, in the shoulder-joint and down the dorsum of the forearm. Deltoid abduction was entirely lost; all other movements were diminished. In addition, when abduction was made passively, the

²⁵ The detailed report will appear in the Transactions of the New York Academy of Medicine, 1896.

scapula, for the first time, began to rotate when the humerus was at about 60°. The electrical changes in the deltoid became more marked; they remained the same or slightly increased in the biceps, triceps and supinator, while similar changes appeared in the supraspinatus, infraspinatus and teres major and minor (?).

I do not see any possible diagnosis to be made here other than a traumatism of the circumflex and musculocutaneous nerves, followed by an "ascending neuritis" to contiguous branches of the brachial plexus. Such a course as from the circumflex along the posterior cord to the musculo-spiral (triceps and supinator), then to the lower subscapular (teres major — the teres minor being involved by extension along the posterior division of the circumflex); and again from the musculo-cutaneous along the outer cord to where the suprascapular nerve (supraspinatus and infraspinatus) is given off, would seem a possible route.

The joint lesion is difficult to explain, but it seems to me to be similar to the one in Case I, and I am inclined to offer the same hypothesis: that is, a trophic change in the area of distribution of the circumflex nerve, somewhere in the abduction curve already described. According to this hypothesis, if the affection of the suprascapular nerve should extend to its articular branch, we might expect further changes in the joint; and yet, as I shall show in other cases, not every case of circumflex injury causes ankylosis. Similarly, not every case of nerve lesion causes other trophic manifestations. We have yet to discover the laws governing the development of the different trophic manifestations, just as we have yet to discover the law governing "ascending neuritis."

CONCLUSIONS.

Looking back over this report, it is evident that as a result of injury, often apparently slight, pain and impairment of motion in the shoulder region are common consequences; that these symptoms may be due to lesions in any one or more of the tissues in this locality; that the pathology of these lesions is obscure but undoubtedly complex and varied; and that hence we are not yet in a position to make many exact inferences, but from the foregoing cases the following conclusions seem justifiable:

(1) That traumatism of the brachial plexus in the region of the shoulder is of common occurrence, since, without any selection of patients, there came to me in an ordinary general surgical clinic, 10 cases within four months.

(2) That it is easy to overlook the nerve lesion, since in many instances the muscular paralysis is not marked, is often insignificant, and is masked by the pain which is apt to be the prominent symptom, and to which the motor impairment is usually attributed.

(3) That in a certain proportion of these cases a more or less marked ankylosis of the shoulder-joint supervenes, the disability being most marked in the field of abduction. In these cases, there are found distinct evidences of affection of the circumflex nerve in its sensory and motor branches, and the presumption appears to be well-founded that this ankylosis is due to a trophic change in the distribution of this nerve to the joint or to the extra-articular tissues under its control, these lying largely, if not entirely, in the abduction curve described. The resulting lesion has been shown in the cases of other nerves to be changes in the

interior of the joint, contraction of the capsule, or conversion into contractile tissue of fibrous tissue; all changes such as would lead more or less in the direction of ankylosis.

No especial difference in the ankylosis was observed when affection of the suprascapular nerve was added to that of the circumflex.

(4) A noticeable point is the practical absence of a predisposing history (although, of course, such accidents might occur as readily to neurotic as to other patients). These patients were all hard-working people, in average health and with negative family and personal histories, unless otherwise noted. All were emphatic in declaring themselves perfectly well except for the shoulder trouble. The emphasis was so noticeable as to suggest a psychic concentration and to seem almost a feature of the nervous affection.

(5) In *all* cases of injury in the shoulder region, the nerves and muscles should be systematically examined by the faradic and galvanic currents, not only at the time of the first examination and diagnosis but at each subsequent examination and dressing. In this way only would it be possible to tell whether there is a nerve injury, either alone or complicating injuries of other tissues.

(6) Especially in all cases where pain is located in the shoulder, and where the temptation is to make a diagnosis of sprain, or peri-arthritis, or rheumatism, should the circumflex and suprascapular nerves be examined, as well as the muscles to which they are distributed. These nerves supply the shoulder-joint, and in three of the cases in this report an abnormal connection between the scapula and humerus was present, while at the same time a lesion was demonstrable in the muscular distribution of one or both of these nerves; and in ten of the cases, pain was felt in the shoulder, while a lesion was demonstrable in the muscular distribution of one or both of the nerves supplying the joint.

(7) A prominent characteristic of these cases is the wide range of electrical reactions found. These reactions are perfectly distinct and well marked when sought for carefully, but it can readily be seen that they might easily be overlooked in a perfunctory examination. A reference to the reports will show that a typical RD, as described by Erb, was seldom present, and even when found only portions of the muscles usually gave such a response; rarely was an entire muscle so affected. It will readily be seen that these cases would remain undiagnosed by observers who would have in mind only the typical RD. But Erb, himself, calls attention to the great range of variability in the nerve and muscle reactions, extending from the normal formula to the complete RD; and this is a matter of common experience to all who devote any care to testing these tissues.

In closing, the writer desires to express her thanks to Dr. Van Arsdale for the opportunity to study these cases, and for his kindness and courtesy in providing her with every facility for such study.

THE DENSITY OF POPULATION IN GREAT CITIES.
— "For thirty-two acres in New York City there are 986.4 people to the acre. The nearest approach to this congested condition is a little spot in Bombay, where there are 759.66 to the acre. The densest London district has only 365.3 people to the acre."

Clinical Department.

SOME CASES OF URETHRAL POLYPUS.¹

BY EDW. REYNOLDS, M.D.

THE female urethra is very rarely the seat of any diseases other than caruncle of the meatus and passing gonococcal inflammations. Its examination is, in consequence, too often neglected; but I have thought that brief notes of these two cases might be of interest in emphasis of the point that in examining the urinary apparatus of women we ought not to fix our attention upon the bladder and ureters to the exclusion of the urethra, which ought, on the other hand, to be carefully looked over as a routine step in the first examination of every case.

CASE I. H. N., bookkeeper, twenty-five years old, came to the Boston City Hospital on December 24, 1896, with the following history: Having always had good local health, she was attacked five months ago during her convalescence from a severe typhoid by frequent and painful micturition, accompanied by a frequent involuntary escape of a few drops of urine. On examination with the cystoscope, a reddened and eroded stripe was seen to extend across the trigonal region from the mouth of one ureter to the other. This is an appearance which might readily be excited by the passage of an acid and exorciating urine for some little length of time, and which would ordinarily disappear after a time under diuretics, or more rapidly after one or two local treatments accompanied by diuretics. I accordingly spotted this reddened stripe lightly with the solid nitrate of silver, and, I may add, afterwards prescribed diuretics, regulation of the diet, etc.

I had supposed that this would have ended the interest of the case, but while watching the appearance of the urethra during the withdrawal of the cystoscope, as is my custom, my attention was caught by an unusual projection which was visible for a moment when the end of the cystoscope was about one-third of an inch outside of the vesical end of the urethra, and which disappeared almost instantly. After re-introducing and withdrawing the cystoscope several times, I finally caught across its edge a delicate papilla-like polypus which was about three-eighths of an inch long, cylindrical in shape, and perhaps hardly more than a thirty-second of an inch in diameter. In order to test its importance as a source of symptoms, I refrained from disturbing it at that sitting. The patient returned five days later reporting but little change in her symptomatology. On examination with the cystoscope the redness of the bladder had greatly decreased, and I thought no other treatment of the bladder necessary, at all events at that time; but again catching the little polypus over the edge of the cystoscope, I pressed it against the edge of the instrument by means of absorbent cotton and readily separated it, apparently at its junction with the mucous membrane; the base was then touched with the solid nitrate of silver.

The patient did not return to the hospital until about a month ago, when she stated that all pain had ceased. In place of urinating about once an hour and twice at night, she now habitually went two hours in the daytime and was not obliged to rise at night at all. She was still at times obliged to urinate as often as

once an hour by day, a frequency which was apparently due to some slight irritation of the left ureter, but a large part of the frequency and all of her tendency to an involuntary escape of urine was apparently due to this insignificant polypus. She was again treated by canterization of the mucous membrane in the neighborhood of the left ureteral orifice and was directed to continue medicinal and hygienic treatment. I have not had any recent opportunity of examining her, but I yesterday received a report to the effect that she now urinates only once in four hours, but has still some slight discomfort for a few minutes afterwards which, however, she does not think worth treating for.

CASE II. Mrs. F., forty-four years old, was seen by me in consultation with Dr. Hedenburg, of Medford, in August, 1897. She was then confined to her bed altogether because she had found that when she was in bed she was able to refrain from urinating for as long sometimes as half an hour, while if she tried to keep about urination was almost constant. Under rest in bed she was improving somewhat at the time I saw her. The history was that twenty years before, after the birth of her first child, she was afflicted by painful micturition, following an extreme distention of the bladder due to her physician's anxiety to avoid the use of a catheter. This lasted only two weeks but some frequency had always persisted and during the last five years she had urinated, as a rule, every twenty minutes in the daytime, and had risen many times each night. Some eight ounces of urine were shown me which had been allowed to stand for several hours, and which contained about an inch of pus at the bottom of an eight-ounce bottle. It was cloudy, slightly alkaline, but not offensive. On microscopical examination, the pus was found to be mingled with phosphates and mucus, and as it did not seem promising, was not examined further. On vaginal examination, the vesical end of the left ureter was found to be enlarged and tender. On examination of the bladder, its mucous membrane was found to be essentially normal, except for a red spot around the left ureteral orifice, which was itself much swollen and pointing. The mucous membrane in this neighborhood was touched up with the solid nitrate of silver, care being taken to avoid the ureteral orifice. The patient was put upon small doses of corrosive sublimate in pill form, large amounts of water, and a carefully regulated diet.

Five days later she reported great improvement, urinating much less frequently, and only twice at night. The ureteral orifice had a much more healthy appearance, but it was now noticed that the circular appearance which the urethral orifice normally shows as it closes over the end of the cystoscope was marred by the projection into it of two fang-like processes from the left posterior quarter. These were red and angry-looking, and were lightly touched with nitrate of silver. Two days later they were retouched.

Owing to my absence from the city, the patient was not seen nor treated again for about six weeks. She then reported that she urinated only every three hours, and for the first time in years was able to walk about freely. She also stated that she now realized the absence of an uncomfortable feeling (she was inclined to call it pain) under the left false ribs, the existence of which she had been unconscious of at her former visit. She was advised to continue the medical and hygienic treatment, but was not examined locally.

¹ Read before the Obstetrical Society of Boston, April 20, 1897.

Five weeks later she reappeared, stating that she had urinated but once in three hours and seldom more than once at night until within the last few days, when she had been afflicted by an urgent and almost constant desire. She had been for two weeks without the bichloride, which had apparently been the cause of rectal tenesmus and bleeding. The left ureter was still slightly tender, but was not so much swollen as formerly. She was put upon five grains of iodide of potash and the elixir buchu et potassi citratis three times a day, but was not examined by the cystoscope at this visit. A week later her symptoms were unaltered. Her bladder was now examined and a red and slightly elevated patch just above the left ureter was touched with nitrate of silver, as were also the fringes about the internal orifice of the urethra. Within a fortnight, that is, by November 17th, the frequency had been reduced to but once at night and to from two to three hours during the day with entire comfort during the intervals. At this time the fringes were represented by short stumps, and during the next six weeks these were cauterized weekly, showing unfortunately an obstinate tendency to reappear.

Since then she has visited me about monthly. The fringes have several times been just perceptible as slight elevations of the mucous membrane, and have then been re-cauterized, the return of symptoms being always strictly coincident with the reappearance of the polyp. The bladder has only twice been the site of slight redness about the left ureteral orifice. There is still a ureteritis, for which the patient is likely to remain under medical treatment for a long time to come, but for several months now she has habitually been able to abstain from urinating for about four hours in the daytime, and during all that time has been disturbed at night on only one single occasion.

These cases, in addition to the interest which so little known a condition of the urethra may excite, seem to me admirable illustrations of the most frequent class of cases which I meet among the urinary affections of women, that is, frequent and painful micturition, which is dependent at bottom, upon an inflammation of the ureter and pelvis of one kidney, but which is rapidly and easily relieved from a symptomatic point of view by a very few topical treatments of the bladder, the improvement being, however, only temporary unless the essential and underlying condition is steadily combated by medical and hygienic methods.

A CASE OF SEPTIC PYELITIS FOLLOWING CYSTITIS, AS A COMPLICATION OF THE PUERPERIUM.¹

BY HENRY EHRLICH, M.D.

THE patient was Mrs. J. J., age thirty-five.

Family history good, with the exception that her mother died of phthisis.

Previous History.—Has had no recent acute illness, and no inflammatory pelvic disturbance. Had a retroversion of the uterus treated a few years ago by Dr. F. W. Johnson, from which she recovered.

A year ago, while pregnant five months, a miscarriage was induced by her attendant, through an error in diagnosis, and during the convalescence she developed a slight vesical catarrh, which disappeared under

appropriate treatment in a short time. This was the first time that she had ever been troubled by any disease of the urinary organs.

She became pregnant for a second time in April, 1896, and her condition during her pregnancy was good; there were no uncomfortable symptoms attributed to the bladder at any time.

She was taken in labor January 18, 1897. Position of child O. D. P. After a tedious labor of eighteen hours she was delivered with forceps. A slight rupture of the perineum was immediately sutured, and it readily united.

Her convalescence for ten days was uneventful. There was no rise of temperature above 99.5° F., and the pulse averaged 74.

On the morning of the eleventh day the patient began to complain of discomfort in the pubic region, and of painful and frequent micturition. This was followed at night by a chill. Temperature 103.5° F., pulse 110, and a sharp pain in the left loin and back.

I saw her the next morning; and on a careful physical examination of the chest nothing abnormal was found in the heart or lungs. Tenderness on pressure was very acute in the left loin over the region of the kidney, and there was an area of hyperesthesia over the lower left chest, including the lower dorsal and upper lumbar vertebrae.

An examination of the pelvic organs at this time showed complete involution of the vagina and uterus and no evidence of genital sepsis anywhere. There was a considerable but painless distention of the abdomen. The urine at this time was pale and cloudy, with acid reaction; specific gravity 1.015. It showed one-eighth per cent. of albumin; and a microscopic examination of the sediment showed a moderate excess of white corpuscles, some blood, and an excess of bladder epithelium.

Calomel and seidlitz powders were at once administered, and they produced copious evacuations from the bowels. Benzoate soda and quinine, a milk diet, and an occasional morphia suppository to control the tenesmus, constituted the treatment at this time; and it was followed by an amelioration of the bladder symptoms. But her general condition seemed to grow worse. There were occasional chills, with erratic flights of temperature to 105° F., and the patient showed evidence of intense septic infection.

On February 4th the pain was still severe in the left loin; there was great restlessness, and hiccough was noted. Pulse 110, temperature 105.2° F.

An examination of the urine showed the quantity in twenty-four hours to be 26 ounces, specific gravity, 1.018, acid reaction; one-fourth per cent. albumin, and in the sediment an abundance of pus, some blood, bladder epithelium, numerous caudate cells from the pelvis of the kidney, and hyaline and granular casts of large diameter were found.

A diagnosis of acute pyelitis following cystitis was made at this time, which was concurred in by Dr. C. W. Townsend, who saw her with me.

On February 5th the patient began to have frequent loose movements, numbering as many as fifteen in the twenty-four hours; this continued for three days, and was not interfered with. The temperature from that time on began to descend, the general condition to improve, and the secretion of urine to increase till 48 ounces were being passed in the twenty-four hours.

On February 8, 1897, the pain in the left loin be

¹ Read, by invitation, before the Obstetrical Society of Boston, April 20, 1897.

gan to disappear; but in the afternoon there was a sharp pain in the right side complained of, in the region of the nipple. The temperature again rose, and on auscultation a pleural friction rub was discovered. This subsided under the local application of an ice-bag. No demonstrable effusion resulted.

The subsequent course of the case was one of gradual improvement. For nine days the temperature rose from one to two degrees at night, and was normal in the morning.

On February 25th a pustular eruption appeared on the trunk and limbs, but under treatment with antiseptic baths, disappeared in the course of a fortnight.

April 10th. Patient is now up and about, has gained in flesh and color, and her strength has improved during the use of appropriate tonics. The urine has now a specific gravity of 1.015, acid reaction; sediment slight in amount, an occasional pus cell and bladder epithelium.

The treatment consisted of fifteen-grain doses of sodium benzoate every three hours, five-grains capsule quinine every three hours, morphia suppositories occasionally for the pain and tenesmus, cold baths as required. Later, the benzoate of soda was replaced by a capsule of boric acid, 15 grains every six hours. From 30 to 40 grains of quinine was administered daily for 21 days. The food consisted of milk and broths. An ounce of whiskey was given every two hours for 10 days, and then gradually reduced.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

REGULAR meeting, April 20, 1897, the President, DR. FRANCIS H. DAVENPORT, in the chair.

DR. EDGAR GARCEAU reported, by invitation,

SOME CASES OF CYSTITIS FROM A CYSTOSCOPIC POINT OF VIEW.¹

DR. HENRY EHRLICH, by invitation, reported

A CASE OF PUERPERAL PYELO-NEPHRITIS.²

DR. EDWARD REYNOLDS reported

SOME CASES OF URETHRAL POLYPUS.³

DR. G. J. ENGLEMAN believed that the local, direct application by means of the cystoscope was of great value where there were small growths or distinct ulcerations.

DR. G. W. KAAH was much gratified to see such good results reported from the use of such small instruments as shown by Dr. Garceau. The large instruments are if possible to be avoided as they cause so much pain.

DR. C. W. TOWNSEND said the case reported by Dr. Ehrlich was of great interest as showing entirely satisfactory results from internal medication in diseases of the pelvis, ureter and bladder. In this case local treatment by means of the cystoscope and ureteral catheter would undoubtedly have caused so much pain and nervous excitement that more harm than good would have resulted.

DR. F. H. DAVENPORT said that, as a rule, he had found that polypi in the urethra gave use to symptoms unless they were in the form of sensitive caruncles.

DR. EDW. REYNOLDS said that nothing works so well in the bladder as nitrate of silver. He is now trying formalin. The handle for the cystoscope showed by Dr. Garceau is certainly most convenient. The smaller the instrument the better. He generally used Nos. 8 or 10; but when there is much to be done, it is well to dilate to No. 13. He has never seen any ill results from cocaine as a local application to relieve pain in these cases.

AMERICAN DERMATOLOGICAL ASSOCIATION.

THE TWENTY-FIRST ANNUAL MEETING, HELD AT WASHINGTON, D. C., MAY 4-6, 1897.

(Concluded from No. 17, p. 426.)

ELEVEN CASES OF POROKERATOSIS (MIBELLI) OR HYPERKERATOSIS EXCENTRICA (RESPIGHI) IN ONE FAMILY,

was the title of a paper by DR. T. C. GILCHRIST, of Baltimore.

Two patients, father and son, were shown at the meeting. They presented lesions upon the hands, feet, legs, wrists and forearms. In the son, now aged twenty-one years, the affection had begun at the age of five, upon the neck, nose, chin and ears. The lesions are very slow in development and spread. The eleven cases are found distributed over four generations. The father's grandmother and one of her brothers had it, as well as the father's brother. Three brothers and a sister of the young man showed characteristic lesions beginning between the fifth and ninth year of age. The sister's two children, a son and daughter, showed the first signs at the age of seven and nine respectively. The reader had examined eight of these subjects personally, and found the father's statement as to identity correct.

The eruption consists of lesions of various sizes and forms. There are two varieties: the smallest, chiefly on the face, consists of minute (one-half to one millimetre in diameter) dirty-brown, semiglobular elevations of horny nature. They grow very gradually; and when they reach the size of a small pin-head (one to two millimetres) the centre sinks in and a peripheral horny ridge is formed. Coursing along the ridge is a minute groove. As extension occurs, the centre of the patch takes on an atrophic though callous appearance. The largest patches are about split-pea size. These lesions return after using the cautery, but not after excision.

Microscopic examination showed that the disease begins as a marked hyperkeratosis of the sweat pores and upper portion of the duct, or of the opening of the sebaceous gland, or of two adjoining openings of both glands. This was followed in some instances by dilatation of the sweat duct and gland beneath, followed by atrophy of the glomerulus. Sections from some of the oldest lesions presented a picture almost like that of psorospermiosis follicularis vegetans (Darier).

Only one case has hitherto been reported outside of Italy, that recently published in the *Cutaneous Journal* by Dr. Hutchins, of Atlanta. The Italian observers have not considered the affection hereditary, but the present series points strongly in that direction.

The reader proposed the name *porokeratosis excentrica*, the first referring to the chief pathological fac-

tor, and the last to a very striking clinical feature, that is, the manner of peripheral extension.

A SCALE OF MEASUREMENTS FOR THE ACCURATE AND UNIFORM DESCRIPTION OF CUTANEOUS LESIONS

was presented by DR. C. W. ALLEN, of New York.

The scale proposed is constructed upon a unit of a quarter-millimetre, which corresponds to the diameter of the smallest lesions of the skin. The numbers range from one to five hundred. Within a circle representing the highest figure are included a series of smaller circles of definite dimension corresponding to the various coins, fruits, seeds, grains, etc., now employed in such an inaccurate, unsatisfactory and unscientific way to denote the size of lesions, plaques, tumors, etc.

The scale numbers can be reduced to millimetres, if desired, by dividing by four. Thus, No. 40 is ten millimetres or one centimetre in diameter. The term *tetmil* is proposed to designate the unit. It is especially in the smaller sizes that accuracy is often of the utmost importance in describing the primary lesions of a disease.

After some discussion, in which it was admitted by all that some more satisfactory plan than the one hitherto followed would be desirable, it was voted to refer the scheme to the Committee on Nomenclature, with a view of introducing it at the next International Dermatological Congress.

A PECULIAR AFFECTION OF THE HAIR FOLLICLE.

This paper was read by DR. JOSEPH GRINDON, of St. Louis, describing a chronic inflammation of the hair follicle, with extension of a portion of the root-sheath *en masse*. This cast-off filum remained closely attached around the hair shaft, being carried up in the growth of the hair, and succeeding extensions forming head-like masses threaded upon the hair in a way to closely resemble nits. There is slight redness about the follicle's mouth; and a slight alopecia results, which is, however, curable. The masses are grayish-white, and bear a close resemblance to the ova of the pediculus capitis. Hence the importance of accurate diagnosis. The masses are found to be made up of cells from both layers of the internal root-sheath surrounded by amorphous detritus and sebum. Trichorrhexis nodosa, monilethrix, piedra, lepothrix and such clinical curiosities as Hodara's and Giovannini's diseases are likewise simulated.

DR. HYDE said the observation here recorded would seem to necessitate a new classification of the diseases of the hair.

IMPETIGO HERPETIFORMIS

was discussed in a paper by DR. M. B. HARTZELL, of Philadelphia, based upon an instance recently observed.

The patient was nearly eighty years of age, and presented upon her abdomen and afterward upon her face, neck and extremities crops of pustules more or less grouped, becoming crusted over and showing military pustules about the margins of the plaques as the central part dried. Death occurred after a train of severe symptoms and several recurrences.

IMPETIGO HERPETIFORMIS, OR DERMATITIS HERPETIFORMIS

was the title of the next paper, by DR. J. A. FORDYCE.

The subject in the case reported, of which colored

drawings and microscopic slides were shown, was a male, in whom groups of vesicles occurred, becoming confluent over the legs and arms. Over the thighs and the abdomen large irregular plaques extended in a peripheral manner, slowly clearing up in the centre. With each new outbreak there was elevation of temperature. After several weeks the lesions slowly disappeared, leaving pigmented areas upon which new groups of vesico-pustules appeared. Papillomatous lesions formed in the axillary spaces. Albumin in small amount and some granular casts were present.

The blood and serum from the punctured vesicles contained large numbers of eosinophile cells. An acute inflammation of the derma and vesicles in the deep layers of the epiderm were disclosed by the microscope. The cell exudation contained many polynuclear leucocytes and eosinophile cells.

The eruption presenting features of both impetigo herpetiformis and Duhring's disease strengthened the speaker's opinion that both should be included in one and the same class.

A paper on

PSEUDO-LUPUS OF THE FACE DUE TO THE PRESENCE AND GROWTH OF BLASTOMYCES OR BUDDING ORGANISMS RESEMBLING YEAST PLANTS

was read by DR. T. C. GILCHRIST, of Baltimore.

The patient was a man of thirty-five years. The lesion began as a "pimple" behind the right ear, slowly increasing over a period of several years, leaving as it extended a linear atrophic scar. The cheek was involved, and in seven years had reached the region of the eyelid. Two years later the nose and opposite cheek became involved.

A second lesion on the hand required four years to cover the back of the member. There was no pain. The appearances were largely those of lupus vulgaris. Specimens were shown of the small bodies found in the military pustules; several grouped together. To discover them sections must be thin and treated with liquor potassæ, alone or with glycerine. They develop by budding, as in yeast, and mycelium also forms in cultures.

Inoculations gave nodules in the lungs of animals, from which pure cultures can be inoculated through a long series, always producing pseudo-tubercles, caseation and pustulation. The blastomyces is hence pyogenic, producing nodules and lesions similar to those of tuberculosis. The disease is named by the author "blastomycetic dermatitis." The bodies are doubly contoured.

DR. FORDYCE spoke of a case now under his observation, in which this might prove the true diagnosis, since until now a diagnosis could not be established.

DR. DUHRING spoke of the value of the microscope in studying such cases, and thought future study of supposed instances of tuberculosis of the skin might show them to be of the nature of the affection here described. The photograph shown represents the same condition as seen in some cases regarded as tuberculosis cutis.

DR. WHITE thought the reader's restriction of lupus verrucosus cutis to certain regions of the body was too limited. He related an instance now under his care in which the nodule occurred upon the sole and side of the foot. It had been acquired in early childhood and he thought the infection had been due to going bare.

foot about the house and grounds where a tuberculous parent had expectorated. He thought Dr. Gilchrist's case might have been a secondary inoculation in an instance of true tuberculosis of the skin.

DR. HYDE thought he had seen much the same appearances as presented in the photograph, and which he had looked upon as tuberculosis. He referred to a case of his own in which upon the ankle of an adult there was a patch of tuberculosis cutis.

DR. GRINDON and DR. KLOTZ joined the other members in congratulating Dr. Gilchrist on the great value of his paper to dermatology.

DR. BOWEN said we no longer had to stick to the old descriptions of Rheil and Paltauf. Plaques of typical tuberculosis verrucosa may be wholly dry and without pustules or vesicles. Dr. Gilchrist expressed his sense of honor in being elected a member of the Association. He had mentioned the occurrence of tuberculosis upon the feet. In the experiments both he and Dr. Stokes had been most careful to exclude tuberculosis which was done absolutely by inoculation experiments. Miliary abscesses are produced by the active budding process of the plant.

The last paper, entitled

LYMPHANGIOMA OF THE LABIA MAJORA,

by DR. WHITE, of Boston, concerned a young girl. The disease was of several years' duration. One papilomatous growth removed and examined showed tissue changes as illustrated by drawings and microscopic specimens. The diagnosis rested between lymphangioma and lymphangiectases. The speaker did not know how the question could be determined.

The conclusions were that it was lymphangioma superficiale.

THE PRESIDENT made a few remarks on retiring, dwelling upon the success of the meeting and its interesting features.

The successor to the chair, DR. HYDE, was then introduced, who thanked the members for the honor conferred.

THE NEW YORK ACADEMY OF MEDICINE. SECTION ON GENERAL MEDICINE.

STATED Meeting, October 19, 1897, LOUIS F. BISHOP, M.D., Chairman.

PROF. WILLIAM OSLER, of Johns Hopkins University, Baltimore, read a thoughtful, scholarly and attractively written address on

INTERNAL MEDICINE AS A VOCATION.

It was a plea for the medical consultants and a description of the methods believed by the author to be the most efficient in preparing the physician for a life-work of this character. It was often reiterated, he said, that the field of the pure physician in this country was becoming more and more restricted, but he contended that there was still an abundant opportunity for properly equipped men possessing the requisite qualifications of mind and temperament, and that each generation had to grow its own consultants.

After referring to such eminent examples as Hosack, Alonzo Clark, Austin Flint, Fordyce Barker and Alfred L. Loomis, who had passed away, he said that their works remained to testify to their ability, but what was really best in them had died with them. Wherewithal should a young man prepare himself for

following in their steps? The character of Lydgate, in "Middlemarch," might well serve for a model, though a less melancholy fate than his was to be hoped for. No more shining example could be desired than the late Austin Flint, and he would assume that the neophyte started out with the same advantages that he had. This was assuming a great deal, however, for he had had the benefit of the teachings of such men as Professors James Jackson and Jacob Bigelow, of Harvard, the influence of which extended throughout his entire professional career.

The young physician, having completed his service as hospital interne, the question arose, Should he go abroad for further study? This might, perhaps, be desirable, but was by no means necessary. Dr. Flint did not go to Europe, but made his reputation in Buffalo and Louisville before he came to New York. Still, a year or two's work in foreign hospitals and laboratories would be most helpful. Whether he went abroad or not, he should eschew all narrowness of spirit, and aim to cultivate broad and liberal views. Even a New Yorker could learn something at the Massachusetts General Hospital and Boston City Hospital, or at the Pennsylvania Hospital and the University of Pennsylvania. Sir Andrew Clark, in speaking to him of his own career, had divided the latter into three periods, namely, ten years for bread, ten years for bread and butter, and twenty years for cakes and ale.

The young man should have high aspirations, as well as breadth of view, and he should strive to embrace every opportunity which brought him in contact with the sick. To this end it would be well for him to secure a position at first as clinical assistant at a dispensary; though he should be careful to avoid everything like specialism. There were three branches which he might perhaps cultivate with the greatest advantage, organic chemistry, physiology and morbid anatomy. In the field of organic chemistry the outlook was never so bright, and in this country particularly there was great need of experts; but unless our young physician, by his previous studies, was already well up on the subject, it would be hardly worth while for him to devote to it the amount of time necessary to make him a master in this department. In that of physiology, experimental therapeutics offered great opportunity and inducements; but if our physician had to limit his studies, he should devote himself especially to morbid anatomy, and in this dry-bread period should see autopsies daily.

In ten years thus employed a serious man would pick up a very fine education, and would be fit to pass from the dispensary to the hospital ward. If he had not previously been abroad he should go now, and it would be an excellent thing for him to devote the summer semester for several years in succession to foreign study and observation. In the meanwhile how was he to live? On crumbs from the tables of those in the period of cakes and ale; from journal work, from students' fees and from work in schools. He should keep his emotions in ice, and shun the temptations of Circe and Amaryllis. Many of the best consultants in London had passed ten, fifteen and even twenty years in dispensary work before getting wards. Teaching was of incalculable value to our physicians, but it should be done in moderation. Too many quiz classes and too much journal work had ruined many excellent medical men. The young man should be ex-

ceedingly careful as to what he wrote. Let him take care of his education, and his reputation would take care of itself.

The bread-and-butter period was to most men more trying than the first stage of their career. The risks were now greater, and many drifted into the specialties or general practice, and many dropped out. It was a well-known fact that those devoting themselves to surgery, in which skilful young hands were as necessary as brains, attained success at a much earlier period than the disciples of internal medicine. At forty-five our Lydgate should have a rich store of knowledge at his command; but he would probably have very little money in the bank. A large city was not necessary for his development, but if he lived in a small place he should make periodical visits to one or more of the great medical centres. In this connection Dr. Osler spoke of the great waste of clinical material frequently seen in small hospitals in cities, and in the hospitals of smaller towns. In twenty years the studious physician could look to a good consulting practice in almost any town of forty or fifty thousand inhabitants.

Even the period of cakes and ale was not without its drawbacks, and the busy consultant, with the thousand and one calls upon his time, often found it pretty hard to keep abreast with the knowledge of the youngsters in the dry-bread stage. In the life of almost every physician there came a time when he was sure to dally with the Delilah of the Press.

Dr. Osler then referred to three well-known medical men who, he said, had been described as follows: the first was a great physician, but no humbug; the second was a great humbug, but no physician; and the third was both a great physician and a great humbug. The first was the most successful of the three, though probably not from a financial point of view.

DISCUSSION OF THE PAPER, WITH REMARKS UPON THE RELATION OF GENERAL MEDICINE TO THE SPECIALTIES.

Dr. WM. M. POLK said that no one could practise in any department without a knowledge of internal medicine. The surgeon and the specialist took up their work at the point where the internal medical man left off, and there was a community of interest between internal medicine and what might be called external medicine. The poorest surgeon was he who began professional work as a surgeon. If such a one had the knowledge to hold his hand, he could often accomplish much more by internal medicine than by surgical interference. As to how to make a good consultant, one of the first things was to know how to write, for the man who was most accomplished in this direction generally had the greatest reputation. In the hospital, however, it was often found to be the case that the man who might not know how to write knew best how to tell you what was the matter with the patient.

Alouzo Clark used to lay more stress on getting close to disease than on anything else. "If you have a ward with thirty patients," he would say, "don't try to find out all about every one of them; but select from them the most pressing and urgent ones, and study these two, three, four or five cases minutely." The increase of specialism he thought was the curse of modern medicine. The specialist was too apt to let his own narrow branch of study overshadow everything else, and this was doing great injury to the profession

and bringing it into contempt among laymen. No one could be a good specialist unless he was first a good general practitioner.

DR. ANDREW H. SMITH said that two different views had been presented by Dr. Osler and Dr. Polk. While the former had lauded the consultant, the latter had made a plea for the general practitioner with an eye to the main chance. Perhaps the best thing was a happy medium between the two. To prepare himself for being such a consultant as was described in the paper, a man would certainly require all the time mentioned, as he would have to become more or less expert in most of the specialties, as for instance, in the use of the ophthalmoscope, the laryngoscope, etc. Yet the late Dr. Flint had no knowledge of bacteriology or such instrument as the laryngoscope. It seemed to him, however, that unless a number of young men are to take the trouble to fit themselves in the manner advised by Dr. Osler, good consultants would soon be very scarce. We had numbers of very clever men in the profession, but very few who stood head and shoulders above the rest, like Dr. Flint, for example. When such men were found, they seemed to possess an intuitive quality of mind and a nicety of observation which took in more than any mere instrument of precision ever could.

When young physicians consulted him in reference to their life work, he was accustomed to tell them to see all the disease they could, and to make their study of every case that they undertook complete and exhaustive. Thorough and conscientious work of this kind would eventually lead to a successful career. There was a distinction between a good diagnostician and a good practitioner. Some men were so much interested in pathological conditions that they were more anxious to get an autopsy than that the patient should get well, and he had frequently met with consultants who were deeply interested in the diagnosis but perfectly indifferent as to the matter of treatment. Trousseau used to speak of what he called the "therapeutic instinct," and he himself had often had occasion to notice the remarkable fertility of resource possessed by certain successful practitioners in small districts.

DR. A. JACOB said that the class spoken of by Dr. Osler was a very small one, but there was also a large class who none the less had made internal medicine their vocation; though it could not be doubted that within the last few years, on account of the growth of specialism, the general practitioner had lost ground. After having spoken of the vast number of different specialists that we had now, including the "appendicitis man," the "stomach man," and the "hemorrhoidal specialist," he said that there seemed to be absolutely nothing left for the general practitioner. He believed, however, that specialism had about reached its height, that the present system would be remodelled, and that in the future we should have fewer specialties and better specialists. In truth, internal medicine, as a vocation, was the noblest of all, more particularly on account of its intimate relations with family life. The names of a past generation, like Bard and Mitchell and Hosack, were still household words, while the memory of the surgeons of the same period had disappeared. The practitioner of internal medicine, he thought, might well be designated as the statesman of the profession.

DR. OSLER closed the discussion. He thought that the plan adopted in London, where the young men

through their long years of dispensary service looked forward to becoming consultants, an excellent one. There was no reason why those aspiring to be consultants should not do some general practice, but, as in London, they should depend mainly for their equipment upon dispensary and hospital work. As to the necessity for such a young man's becoming expert in various specialties, referred to by Dr. Smith, the use of such instruments as the ophthalmoscope and the laryngoscope was now required in the course of study at all the best medical colleges, and there was no reason why he should not keep up his familiarity with them during his years of dry bread. While Dr. Flint might not have had a personal knowledge of bacteriology and other scientific subjects, he would venture to say that he always had about him young men who were thoroughly versed in them. What was always to him one of the most striking characteristics of this great teacher and consultant was his remarkable receptivity. Up to the day of his death he remained young in feeling, and he habitually kept himself in touch with the most advanced thought of the day.

In the mind of the consultant the matter of diagnosis was rightly regarded as the all-important consideration, since everything else depended upon it. This was well illustrated in three cases which he had seen within the last twenty-four hours. In the first, the patient was dying of pernicious anemia, a condition which had been previously mistaken for malarial cachexia. The second case was one of cancer of the stomach, where the diagnosis was of no value so far as the matter of treatment was concerned. The third was one of stone in the common duct, and in this instance hundreds of dollars might have been saved by an earlier recognition of the difficulty. The outcome of the case would depend very much on the surgeon to whom it was referred. The position of internal medicine in this country, he thought, would be better and better as an increased number of young men devoted themselves to clinical teaching.

Recent Literature.

The Diseases of Infancy and Childhood. By L. EMMETT HOLT, A.M., M.D., Professor of Diseases of Children in the New York Polyclinic. New York: D. Appleton & Co. 1897.

This is the latest and one of the most valuable additions to the now rapidly increasing list of works on Pediatrics by American authors. It is well arranged and well printed. The illustrations are, as a rule, of but moderate merit and the colored plates disappointing. It is, as a whole, clearly written, but the use of medical terms is often inexact. The most noteworthy feature of the book is the treatment, which is complete, minute and up to date. While recognizing the supreme importance of nursing and diet in the care of children, the author does not underestimate the value of drugs or hesitate to use them on their proper indications. We feel that this portion of the book will prove most valuable to both students and practitioners.

In a work of such exceptional and uniform merit it is difficult to find portions worthy of either special praise or condemnation. Some portions, however, seem worth individual consideration. The chapter on

the Peculiarities of Diseases in Children, especially the portion dealing with therapeutics, is unusually good. We had supposed, however, that the oil-skin jacket had passed away, together with the jacket-poultice, and that the value of inunctions of oil or cocoa-butter was far from proved. In the section on Diseases of the New-Born we find a new disease—"inanition fever."

The section on Nutrition is exceptionally good throughout. In his preface the author apologizes to a certain extent for the space devoted to this subject. We feel that this is uncalled for, however, and that even more space might well have been devoted to the subject. Even now we sometimes have to read between the lines to fully appreciate it. We feel, moreover, that more can be done in modifying the constituents of breast-milk than the author would lead us to believe. The classification of Derangements of Nutrition is original and well worth imitation in the future. We think, however, that the author has not sharply enough limited the term "marasmus," as he includes under it not only a disease, preferably known as "infantile atrophy," but also most secondary conditions of wasting. We feel, moreover, that infantile atrophy belongs more properly among diseases of the digestive tract.

We fail to see how the author can reconcile the classification of Diseases of the Digestive System adopted in this work with that to which he gave his approval as a member of the committee of the American Pediatric Society on the nomenclature of the diseases of the gastro-enteric tract in 1894, and which was adopted by the society. We think that a uniform nomenclature for these diseases is of the utmost importance, and that he has retarded the progress of our knowledge of them by not following the classification adopted by the national society. It seems to us, moreover, that, except in the names used, he has followed it in all essential particulars. We cannot see, however, why the disturbances resulting from improper food should be grouped under the head of chronic intestinal indigestion any more than elsewhere. With the exception of the classification, however, this section is most admirable and will well repay the most careful study. The treatment of these diseases is very good. We cannot agree with the author, however, that milk should not be given in the acute stage of gastro-enteric infection. We are glad to see that operation is favored in tubercular peritonitis, but are surprised that the tuberculin reaction is not mentioned as a means of diagnosis.

The section on Diseases of the Respiratory System is also of the greatest merit and shares the honors of the book with those on Nutrition and the Digestive Tract. We think, however, that catarrhal spasm of the larynx (spasmodic croup) is better considered as a variety of acute catarrhal laryngitis than as a separate disease. Under the term "asthma," the author, according to his own definition, includes many conditions which manifestly do not belong there. The article on Pneumonia is very good, and that on Broncho-Pneumonia is the best we have ever seen. We think the author makes a mistake in calling pneumonia with pleurisy "pleuro-pneumonia," and that such a term can only lead to confusion.

The section on the Diseases of the Blood, as well as the references to the blood throughout the work, are entirely inadequate, frequently misleading and often

erroneous. In the chapter on Malaria, moreover, the different forms of the malarial organism are not recognized, the difficulty of finding it is exaggerated, and the importance of its presence in diagnosis underestimated. The section on Diseases of the Lymph Nodes, on the contrary, is new in arrangement and exceptionally good.

The sections on Diseases of the Circulatory and of the Nervous Systems, as well as that on the Specific Infectious Diseases are uniformly good. Vaccinia is confused with vaccination, however, and we cannot subscribe to the statement that endocarditis is not common in scarlet fever. The article on Pseudo-Diphtheria is a new idea and, we think, a good one.

On the whole, the book is one of the best in English on Pediatrics, and is well worth perusal by all who are interested in this subject.

A Handbook of Medical Climatology, Embodying its Principles and Therapeutic Application, with Scientific Data of the Chief Health Resorts of the World. By S. EDWIN SOLLY, M.D., M.R.C.S., late President of the American Climatological Association. In one octavo volume of 470 pages, with engravings and colored plates. Philadelphia and New York: Lea Brothers & Co., Publishers. 1897.

It is strange, considering the important position as a therapeutic agent which climate has taken in the opinion of both the medical profession and the general public, that no systematic treatise on medical climatology has previously appeared. It has been left for Dr. Solly to collect the facts on which our knowledge must be based from the scattered sources which contain them, and from them to draw such deductions that, as he says, it is perhaps "hardly too much to say that it is possible to prescribe a climate with as much precision as a drug and with far greater effect in certain cases." A close study of the subject for thirty years has given the author a special fitness for the work and that he has done it well will be evident to any one who will give himself the pleasure of reading his interesting pages.

The subject-matter is divided into three sections, the first of which deals broadly with the principles of medical climatology and describes the close connection of this science with physics, meteorology, ethnology, geographical pathology, etc. The second treats of the therapeutics of climate in relation to disease, and phthisis being by far the most important from this standpoint naturally occupies most of the space. The various climatic factors which affect the prevalence of phthisis are described at length, as well as the relative prevalence of its different forms in reference to the selection of an appropriate climate for a developed case. The third section deals with special climates as typified in selected resorts, and contains a map of information as to their climate, elevation, population, drainage, etc., nowhere else obtainable in such condensed form, not the least important of which is a description of the accommodations and amusements provided for the invalid, on which his comfort and happiness (and indirectly his health) must depend.

The text is enriched by several finely executed maps. On laying down the book one is prepared to agree with the author that climatology is not the pure empiricism that many think, but is a science founded on natural laws and strengthened by rational experience.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 28, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

IS THE SYMPATHETIC SYSTEM THE SEAT OF THE EMOTIONS?

THE theory that the sympathetic ganglionic system is the physical basis of the emotional and specifically of the moral nature of man has been advocated with much ability by Dr. Maurice R. Bucke, of London, Ontario, who has made many contributions to modern psychology,¹ and whose paper on "Mental Evolution" at the meeting of the British Medical Association this autumn attracted much attention.

Bucke's contention is that the higher cerebral ganglia are the seats of the intellectual nature, and the sympathetic ganglia the seats of the emotions. In other words, the two groups of functions are distinct and have separate centres.

This view assumes that the emotions, love, fear, hate, etc., are simple and homogeneous, and that when elaborated in the sympathetic ganglia they have no admixture of concept or ideation, which are functions of the cerebrum. In fact, this author affirms that "any idea may exist without the coexistence of any emotional state"; and conversely, "any simple emotional state—faith, love, fear, hate—may exist without being associated with any idea." Is this true?

Is it not certain that in love and hate, trust and fear, which Dr. Bucke regards as the basis of the moral nature, the concept of the person or thing loved and hated (a cerebral fact) is an inseparable part of the emotion itself, just as, according to psychologists, the physical expression of the emotions is also an inseparable part? "A purely disembodied human emotion," says Professor James, "is a non-entity."²

In one respect Dr. Bucke's view that the sympathetic system is the seat of the emotions finds some countenance in Lange's theory³ founded on physiological experiments, that "the immediate physical expression of the emotion is a vaso-motor modification, and that the other physical manifestations are pro-

¹ See especially *Man's Moral Nature*, G. P. Putnam & Sons, New York.

² William James: *Psychology*, vol. ii, p. 452.

³ Lange: *Les Emotions, Etude Psycho-physiologique*, Paris, 1895, p. 93.

duced by the vaso-motor troubles — the modifications of the blood capacity of the different organs, the changes which are produced in the aspect of the organ and in its functions." This thought may not at first sight seem very clear, but he illustrates it in various ways. "Is it not possible," he asks, "that in sorrow the muscular enfeeblement is due to the anemia produced in the nervous system as well as in the skin and other organs by the constriction of the small arteries? And in rage, does not the uncontrollable force manifested have its source in the great afflux of blood which goes to the brain as well as to the skin and mucous membranes?"

However this may be (and doubtless these considerations are for the most part speculative), it remains certain that every emotion has an ideal side, and that if there are physical manifestations which originate in ganglia which belong to the sympathetic system, there are other equally notable manifestations which are properly ascribed to the cerebro-spinal system.

We may in this connection allude to the fact that in the light of evolutionary psychology, an emotion, of whatever nature (and the moral sentiment is included) is an exceedingly complex aggregate of feelings and associated ideas. Herbert Spencer calls emotions "presentative-representative feelings,"⁴ "in which a sensation, or group of sensations and ideas arouses a vast aggregation of represented sensations; partly of individual experience, but chiefly deeper than individual experience, and consequently indefinite." He cites as an example the emotion of terror: "Along with certain impressions made on the eyes and ears or both, are recalled in consciousness many of the pains to which such impressions have before been the antecedents; and when the relation between such impressions and such pains has been habitual in the race, the definite ideas of such pains which individual experience has given are accompanied by the indefinite pains that result from inherited experiences — vague feelings which we may call organic representations. In an infant crying at a strange sight or sound, while yet in the nurse's arms, we see these organic representations called into existence in the shape of dim discomfort to which individual experience has yet given no specific outlines." In this writer's "Data of Ethics," in the chapter entitled "Psychological View," he shows the application of this conception to man's moral nature which Dr. Bucke thinks has undergone [entire?] development during the last ten thousand years.⁵

It is, moreover, argued respecting the emotions that we *feel* that these have their seat not in the head but in the body, and the languages of all nations refer the emotions to the heart, in and about which organ are grouped some of the larger ganglionic masses of the great sympathetic.

This can hardly be regarded as a serious argument, since the indications which consciousness may give as to the seat of an emotion are very vague. Who can

tell by his feelings whether his hopes and fears begin in the cardiac plexus, solar plexus, or cortex cerebri? Consciousness may locate correctly a pain and even the hypochondriacal distress of certain abdominal diseases, but an emotion, in whatever part it may originate, is too rapidly diffused in its physical effects to admit of any strict localization.

Is there an "abdominal brain" (comprehending especially the solar and uterine plexuses) as some physiologists and notably Dr. Byrom Bramwell think, with a quasi consciousness and a mode of suffering of its own? We may speculate regarding this question, we cannot answer it, though the extent to which some persons are governed by the stomach or the uterus might indicate to others the truth of the affirmation.

The cerebral origin of many emotions seems evident, and in all (as stated above) the participation of sensory and ideational processes can be shown on analysis. Is emotion — or rather feeling — only another aspect of intellect, both being modes of a primary sentience as comparative psychology is said to teach?

It is noteworthy that writers on mental alienation class the affective insanities as *cerebropathies*, placing mania and melancholia, those emotional diseases *par excellence*, under the head of "General Ideational Insanity"; and that Maudsley, one of the most philosophical of writers, speaks of melancholia as a "neuralgia of the cortical conscious cells."

PROTECTION IN FRANCE AGAINST FOREIGN MEDICAL PRACTITIONERS.

As many of our readers already know, there has been a constantly increasing disposition in France towards "protection" as a politico-economical policy, and along with this an illiberal and ungenerous discrimination against the practice of medicine by foreigners. At present the head of the French Cabinet, M. Méline, is and has been for years the apostle *enragé* of "protection" in France. The present laws are practically prohibitory of medical practice by foreigners not already established, and if such regulations remain in force after the passing away of their fellow-countrymen now in practice, American and English travellers are going to find themselves in an awkward and disagreeable situation.

A correspondent, who personally has nothing to lose by the present situation, writes as follows:

You may possibly have heard that the French have been legislating recently in such a way against foreign doctors that, as their law now stands, it is *impossible* for a foreign doctor to come and practice in France. To do so he must first take the French B.A. degree, and then go through the five-year curriculum. This means that he must spend about seven years in France before being allowed to practise, and this no matter who he may be, how well known, or what positions he may have occupied.

You will see at a glance that this is practically a prohibitive law. Suppose, for instance, that your health broke down and you wished to come and practise in the south of France for the sake of the climate. It could not be done.

I consider this law, although as you will see *it favors me*, preventing other men from coming here, as so contemptible that

⁴ Classification of Feelings, in Illustrations of Progress, D. Appleton & Co., New York.

⁵ Montreal Essay on Mental Evolution.

I think the men at home ought to take some notice of it, by legislating against the foreigners who shut us out — French, Germans, Swiss, and (soon) the Italians — and also by not sending their patients to French practitioners here or in the South.

I think the action of the French authorities is one that is grossly unfair, and that in the long run, when the present men who are here die off, it is going to cause a great deal of annoyance and trouble to the travelling Americans. The Frenchmen never speak English, and you know that all their habits of hygiene and their care of the sick, as well as methods of treatment, differ widely from ours. The day will come, with the present law, when Americans will have no one to fall back on but these Frenchmen, who, whatever their merit may be, which I do not contest for a moment, will never get on well with Americans, and particularly with Americans ignorant of the French language. Fancy yourself, for instance, falling ill in Russia with no one but a Russian physician who didn't know English!

NARCOTISM AND ALCOHOLISM.

At a meeting of the New York Medico-Legal Society held October 19th, Dr. J. B. Mattison read a paper on "Narcotic Inebriety in America," in the course of which he said he was happy to make the announcement, based on extended observation, that the use of narcotics was on the wane in this country. In regard to opium inebriety he said that its decrease was mainly due to the substitution by physicians of codeine, phenacetine and electricity for morphia. At the same meeting Dr. Agnes Sparks, of Brooklyn, read a paper on "Alcoholism in Women." Alcoholism in women, she said, had heredity as its origin to a lesser degree than in men. Inebriety from a fondness for alcohol also obtained less often in women, and this neurosis therefore presented strongest proof that its origin lay in perturbed physical conditions. First in frequency was a condition due to lack of nutrition and wear and worry of domestic life and social demands. The other most common cause was pain and unrest incident to disorders of sex for which solace was sought in the anesthetic and paralyzing effects of alcohol. The treatment she advised was curative and preventive. The remedial agents of greatest value were strychnia, arsenic, electricity and hypnotism. At first it was often advisable to allow a certain amount of alcoholic stimulus, preferably given in milk; but this should be discontinued as soon as possible. She gave the first place to strychnia, hypodermically, administered daily. Hypnotism acted best in periodic cases, the *séances* being given between the drinking bouts. No case, she thought, should be deemed beyond hope until every aid that scientific treatment could now surely extend should prove of no avail; alcoholism being not only a curable but a preventable disease. In the discussion that followed the reading of the paper other physicians took a less hopeful view of the subject. Dr. Arthur C. Brush said that during the last few years he had noticed a considerable increase in drunkenness among women, and Dr. I. N. Quimby said that he had known and treated more than two hundred female inebriates, and had not been able in any way to reform more than ten per cent. of them, the results being less favorable than in the case of male drunkards.

MEDICAL NOTES.

DEFALCATION OF A HOSPITAL OFFICIAL. — It is reported that the secretary of a London hospital devoted to diseases of the chest, has disappeared leaving behind very large defalcations.

DR. VAN REYPEN APPOINTED SURGEON-GENERAL OF THE NAVY. — President McKinley has appointed William K. Van Reypen Surgeon-General of the United States Navy, to fill the vacancy caused by the death of the late Surgeon-General Newton L. Bates.

YELLOW FEVER NECESSITATES A CHANGE OF CAPITAL. — Owing to the prevalence of yellow fever in Montgomery, Ala., the State government has been removed to Birmingham. The governor and all of the State officers are transacting business from that point.

AN INTERNATIONAL LEPROSY SOCIETY. — At the International Conference on Leprosy, the sessions of which have just ended at Berlin, a commission was appointed to prepare plans for the formation of an International Leprosy Society. Professor Virchow is the president of the commission.

A MEDICAL MAN DIES UNDER CHLOROFORM ANESTHESIA. — Dr. Robert Smith, Medical Superintendent of the Dunston Asylum, Gateshead, England, died recently while under the influence of chloroform, in the Stockton and Thornaby Hospital. He was about to undergo an operation for fistula.

YELLOW FEVER IN THE SOUTH. — During the past week the yellow-fever situation in the South has not improved; and on Tuesday, October 26th, 50 cases and 5 deaths were reported in New Orleans. The cases are now widely diffused throughout that city, and are occurring in districts which have heretofore been healthy.

CONSUMPTIVES IN CALIFORNIA. — It is reported in the daily press that the State Board of Health of California has issued orders directing physicians in charge of asylums to segregate consumptives and report the number in each asylum. This is said to be preliminary to the enforcement of rules for segregating consumptives in all health resorts.

THE GERMAN PATHOLOGICAL SOCIETY. — At the recent meeting of the German Scientists and Physicians at Brunswick a new society was organized, to be known as the German Pathological Society. It is to hold its meetings each year in the same place and just after the sessions of the former society at the close of which it was organized this year. Professor Virchow is the president of the new society, and Professor von Recklinghausen its secretary.

SERUM DIAGNOSIS AND TYPHOID EPIDEMICS. — The determination of the question whether the cases of simple diarrhea which so often precede or accompany epidemics are perhaps unrecognized cases of typhoid and may in some cases be the original source of the epidemic is a legitimate and proper field for the employment of serum diagnosis. This test was applied in connection with the Maidstone epidemic

to eight cases of simple diarrhea by Surgeon Captain Smith, at the Pathological Laboratory of the Army Medical School at Netley, with the following conclusions:¹ these examinations as detailed show that it is unsafe, without a controlling bacteriological examination, to infer that cases of diarrhea which occur either before or in the course of epidemics of typhoid fever are in any way cause or consequence of the prevailing epidemic.

CARBOLIC ACID IN A CLARET BOTTLE.—At University College, London, recently two workmen drank carbolie acid which was supplied to their foreman from the college laboratory in a claret bottle without a label. They drank it supposing it to be claret, and one of them died in consequence. In the words of the *Medical Press and Circular*: "One does not expect recklessness of this kind in connection with a chemical laboratory, and it is to be hoped that the authorities responsible for the proper ordering of the seat of learning concerned will take immediate steps to reorganize the methods of their subordinate officials. Whereas from 1861 to 1864 only two persons died from accidental carbolie-acid poisoning, in London, yet from 1891 to 1894 no less than 129 persons met with a similar untimely end. That fact may be commended to the attention of the University College officials." How many deaths and accidents, here and abroad, will it take to make health authorities recognize that carbolie acid is a poison, and take appropriate action?

ULCERATIVE ENDOCARDITIS TREATED BY ANTISTREPTOCOCCIC SERUM.—Dr. J. W. Washbourn, Physician to the London Fever Hospital and Assistant Physician to Guy's Hospital, reports (*Lancet*, September 18th) a case diagnosed as ulcerative endocarditis successfully treated with antistreptococcic serum. He feels quite clear as to the fact that the pulmonary valve was affected, and that the diagnosis was justified. The result of the treatment was most striking and in Dr. Washbourn's opinion it saved the patient's life. The pyrexia ceased after the first fortnight. The injections were given daily in doses of twenty cubic centimetres for two months, when the patient was discharged from the hospital well, except for pulmonary regurgitation, and was seeking a situation a month later. The large amount of serum used is worthy of record. The treatment lasted nine weeks, during which time 1,030 cubic centimetres of serum were injected in 59 doses. The only ill-effect was a transient rash. Throughout the case the cardiac symptoms remained in the background, the infective process being the most prominent feature. The antistreptococcic serum was used because it was thought that the case was most probably one of streptococcic infection, although there was no bacteriological evidence of the presence of streptococci in the blood.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, October 27, 1897, there

¹ British Medical Journal, October 16, 1897.

were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 42, scarlet fever 26, measles 7, typhoid fever 13.

DEATH AT AN ADVANCED AGE.—Mr. Joseph Manuel died at Kennebunkport, Me., Friday, aged about one hundred years. He leaves a wife, to whom he had been married seventy-seven years.

A NEW "CONTAGIOUS HACK."—The city of Newton, Mass., has ordered a new ambulance for the transfer of patients suffering from contagious diseases, which is to be fitted with the best modern appliances for the comfort of the sick passengers. The old "contagious hack" which is now in use is said to have become too dilapidated for further service.

SUFFOLK DISTRICT MEDICAL SOCIETY. CENSORS' EXAMINATION.—The Censors of the Suffolk District Medical Society, officiating for the Society at large, will meet to examine candidates for admission to the Massachusetts Medical Society at 19 Boylston Place, on Thursday, November 11, 1897, at 2 p. m. Candidates must make personal application to the Secretary, and present their medical diploma, or its equivalent, at least three days before the examination. For further particulars apply, from 2 to 3 p. m., to John Dane, M.D., Secretary, 29 Marlborough Street, Boston.

THE MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH.—At the quarterly meeting of the Massachusetts Association of Boards of Health, held recently at the Parker House, President H. P. Walcott was the presiding officer and the subject of "The Prevention of the Pollution of Milk Supplies" was the chief topic under discussion. Prof. W. T. Sedgwick reported, for the Committee, rules for the protection of milk-supplies from pollution.

THE NAVAL SURGEONS' VISIT TO THE BOSTON CITY HOSPITAL.—Medical Inspector and Surgeon M. C. Dreunau of the White Squadron and the medical officers attached to the fleet visited the City Hospital during the recent stay of the warships in Boston harbor, and inspected the entire institution. They were received by President A. Shuman of the trustees, assisted by Dr. Rowe, superintendent of the hospital, and a committee of the visiting staff.

A COTTAGE HOSPITAL FOR LACONIA, N. H.—The trustees of the Laconia Cottage Hospital Association have decided to lease the Rhoda C. Ladd property for a cottage hospital for a term of five years. The Ladd estate was bequeathed to the city for a hospital several years ago, and this is the first action taken toward establishing the institution. The cottage hospital movement is merely preliminary to the establishment of a permanent hospital within a few years.

NEW YORK.

NEW YORK COUNTY MEDICAL ASSOCIATION.—At the first meeting, October 18th, after the summer vacation of the New York County Medical Associa-

tion, Dr. John Shrady read a memorial address on the life and character of the late Dr. J. Lewis Smith, and Dr. Austin Flint a similar address on the late Dr. William T. Lusk. At the same meeting Dr. Achilles Rose, who recently returned from a visit to Greece extending over several months and who published a valuable paper on Greek Anthropology in the *New York Medical Journal* of September 25th, made some interesting remarks on the present condition of that country, the prevailing misrepresentation in regard to its people, and the danger of its subjugation again to Turkish dominion.

ST. LUKE'S HOSPITAL.—The annual meeting of the Society of St. Luke's Hospital was held at the hospital buildings on October 18th. The report made by the Board of Managers showed that the death-rate from all causes for the year was 10.3 per cent. In the medical department 1,201 cases were treated, and 1,243 in the surgical department, exclusive of the out-patient department. The total expenses for the year were \$153,299, and the deficiency of income as against expenses for the year \$57,499. The report of the Building Committee stated that the cost of the buildings was \$1,749,605, which added to the cost of the land, \$530,000, brought the total outlay for the erection of the new St. Luke's Hospital up to the sum of \$2,279,605.

THE BOARD-OF-HEALTH LEPEERS.—Four of the five patients constituting the leper colony at the hospital for contagious diseases on North Brother Island recently left their quarters there, and the Board of Health has refused to take them back, on the ground that in this climate and under the conditions prevailing in New York City leprosy can no longer be regarded as a contagious disease. Two of the lepers are Chinese and the other two natives of the West Indies, and all of them have been on North Brother Island for over a year. At present three of the men are quartered in a tent on the grounds of Bellevue Hospital, and the fourth, a mulatto, is said to be stopping with his mother in a house on East Sixty-second Street. The Commissioners of Public Charities have decided that the lepers come within their jurisdiction, rather than that of the Health Department, and they will probably be permanently cared for on Blackwell's Island. A year ago, Dr. Roberts, Sanitary Superintendent, in a report on the leper colony in charge of the Board of Health, recommended the discharge of the patients; affirming that no harm could come to those who might be brought in contact with them, and expressing that it was an unjust and needless hardship to keep them prisoners in isolated confinement. On December 29th last a special committee on leprosy of the Medical Society of the County of New York, consisting of Drs. George B. Fowler, A. A. Smith, George H. Fox, E. R. Bronson and H. G. Piffard, made a report declaring that leprosy is not necessarily contagious and deprecating indiscriminate segregation. "It would appear," the report stated, "that other conditions than that of mere proximity are essential

before leprosy can be accounted a contagious disease. What these conditions are, whether they relate to location, soil, climate, food or mode of habits of life, is unknown; but with little doubt it is because of their absence that this and other similarly favored localities have thus far remained exempt from any prevalence of leprosy." The International Congress of Leprologists, which has lately held its meeting in Berlin, under the influence of Professor Hansen of Bergen, Norway, and against the views of Besnier, of Paris, affirmed the opinion that leprosy is contagious, though not hereditary, and that isolation is desirable and to be enforced by public authorities under certain conditions.

Miscellany.

LORD LONDONDERRY ADVOCATES DISEASE DISSEMINATION.

["Dairy farmers in this country have a genuine grievance in being compelled to produce milk and butter under the best sanitary conditions, and to compete in their own market with an unlimited quantity made in Denmark under no kind of sanitary conditions at all."]

"The above utterance is the calm, deliberate statement of a person who claims to rank as a statesman, who has been Viceroy of Ireland, is a territorial magnate, and has an important influence in the legislation of the United Kingdom. It is by Lord Londonderry, reported in the *Daily Graphic*, September 1st. We have heard and read many dangerous statements by men of supposed light and leading, but we doubt if even the worst minded and ignorant of politicians could sink to a deeper depth than this ex-viceroy and statesman has done in his speech at the Sedgefield Agricultural Show on August 31st. It is not a pleasant thought that any body of Englishmen can be found so servile as to refrain from discountenancing such an utterance because it comes from a lord.

"Put into plain English, what does Lord Londonderry complain of? He complains that the dairy farmer is compelled to preserve sanitary conditions in his business, that is, that he must no longer, as he did in the had old times, wash his pans in sewage-polluted water, have his sheds ankle deep in foul, reeking animal droppings, and send out milk loaded with deadly germs to the public, spreading suffering, disease and death broadcast. There is no article so liable to spread infection as milk is, and, even with the sanitary restrictions which Lord Londonderry considers 'a genuine grievance,' a great amount of disease is now disseminated by milk. Milk is the principal food of infants, but, outheroding Herod, Lord Londonderry would not only have infants doomed to typhoid, scarlatina, etc., but would give filth a free hand, and spread disease and death everywhere amongst adults, in order that his class—the landlords—may spend a little less in necessary public-health work, sewerage, drainage, pure water-supplies, and the like, and be enabled to screw more rent out of their tenants, who now have to spend some money which could be extorted as rent in sanitary improvements required for their own health and the safety of the public. Such opinions are worse than those of the most raving anarchist. Yet their author was on Tuesday posturing before the Duke and

Duchess of York in Ireland and proud of having entertained royalty nineteen times.

"He would be better if he entertained beliefs less like unto those of Swift's Yahoos, which were, after all, only the creation of a satirist, whilst Lord Londonderry's are the deliberate expressions of a person posing as a statesman, who has been Viceroy of Ireland. We hope, for the well-being of humanity, that even amongst lords this insanitary person will find no imitators and no followers." — *Food and Sanitation.*

SERUM DIAGNOSIS OF TYPHOID FEVER.

The following circular, addressed to the President of the Board of Health of the Province of Quebec has been issued by and received from Dr. Wyatt Johnston, Bacteriologist to the Board:

The simple technique recommended by this laboratory for the serum diagnosis of typhoid, by means of dried blood, has been found, after a year's trial, quite satisfactory for the practical work of diagnosis.

At the same time (as was recently explained by a Committee of the American Medical Association, of which I was a member), although for routine diagnostic work even the very simplest methods may give good practical results, yet for recording scientific observations quantitative methods should be selected. This is especially necessary in reporting exceptional cases at variance with the general results of others, or where the observations are made the basis of generalizations.

I have found that good uniform quantitative results can be readily obtained with the dry blood method by taking in the first instance drops of uniform size, collected by means of a wire loop (I use 20 gauge copper wire, two millimetres inside diameter), which is returned with the outfit and used subsequently to obtain dilutions of known strength. The method has been described more fully in a joint paper by myself and Dr. Harold Thomas before the British Medical Association at Montreal, on September 2, 1897.

For quantitative work, the blood is dried on an ordinary glass slide, or non-absorbent paper can be used if preferred. One of the outfits will be sent, when a quantitative estimation is desired, or to any who are practically interested in the matter. As already stated, I do not find quantitative work necessary for routine diagnosis, preferring to employ cultures having a sensitiveness so low as to give no reaction at all with non-typhoid.

In addition to the previous observations made by myself and Dr. D. D. McTaggart as to the use of attenuated cultures, I wish further to call attention to the importance of paying special care to the reaction of the test culture media. Bouillon cultures showing after twenty-four hours' growth of typhoid at 37° C., a slight uniform cloudiness only, and quite free from scum or sediment, offer the greatest security against pseudo-reactions. I find that such cultures can be obtained by using bouillon just on the verge of litmus acidity, giving no blue whatever to the red paper. From five per cent. to six per cent. of normal alkali are required to make this bouillon neutral to phenol phtalein.

Cultures which give a heavy bouillon growth are the ones which are most liable to give pseudo-reactions, that is, to clump in a deceptive manner spontaneously or with non-typhoid blood. If the culture is too acid the reaction may be defective. With a proper culture, I have never met with the typical reaction apart from typhoid fever. On the other hand, by employing certain incorrect methods of preparing the culture I can obtain at will very perplexing pseudo-reactions with a large proportion of non-typhoid bloods. This may be the explanation of a number of anomalous published results, though the difficulties can be also doubtless avoided by other means than those indicated here.

METEOROLOGICAL RECORD

For the week ending October 16th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Barometer	Thermometer.		Relative humidity.		Direction of wind.		Velocity of wind.		Weather.		Rainfall in inches.

Amesbury	10,320	—	—	—	—	—	—	—	

Deaths reported 2,851; under five years of age 974; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping cough, erysipelas, and fevers) 436; consumption 300; acute lung diseases 294; diphtheria and croup 116; typhoid fever 73; whooping-cough 16; malarial fever 15; scarlet fever 14; cerebro-spinal meningitis 12; measles 10.

From whooping-cough New York 7, Brooklyn 3, Chicago and Cincinnati 2 each, Baltimore and Brockton 1 each. From malarial fever St. Louis 11, Nashville and Charleston 2 each. From scarlet fever New York 7, Chicago 2, Brooklyn, Boston, Cincinnati, Cleveland and Cambridge 1 each. From cerebro-spinal meningitis New York 4, Boston 2, Washington, Providence, Worcester, Fall River, Lynn and Chelsea 1 each. From measles New York 5, Brooklyn and Providence 2 each, Chicago 1. From erysipelas New York and Chicago 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending October 9th, the death-rate was 16.2. Deaths reported 3,414, diarrhea 131, diphtheria 86, fever 73, measles 52, whooping-cough 47, scarlet fever 45.

The death-rates ranged from 26.2 in Bolton to 9.4 in Portsmouth; Birmingham 16.3, Bradford 14.4, Croydon 9.9, Gateshead 18.1, Hull 16.5, Leeds 18.2, Leicester 13.3, Liverpool 20.9, London 15.5, Manchester 21.7, Newcastle-on-Tyne 16.5, Nottingham 13.9, Sheffield 19.4, West Ham 16.0.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 16, 1897, TO OCTOBER 21, 1897.

CAPTAIN PETER R. EGAN, assistant surgeon, U. S. Army, is granted leave of absence for six months.

CAPTAIN J. D. POINDEXTER, assistant surgeon, U. S. Army, now on temporary duty in New York City, is ordered to Fort Hamilton, N. Y., for duty, when relieved from present duty by CAPTAIN WM. C. GORGAS, assistant surgeon, U. S. Army.

LIEUT. GUY C. M. GODFREY, assistant surgeon, U. S. Army, is relieved from further duty at Fort Yellowstone, Wyo., and is ordered to Fort Yates, N. D., for temporary duty.

CAPTAIN NORTON STRONG, assistant surgeon, U. S. Army, upon being relieved from duty as attending surgeon and examiner of recruits at Chicago, Ill., to await orders in that city for the convenience of the government.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, November 1st, at 8 o'clock. Dr. F. S. Watson will read a paper on: "Some Recollections of the Twelfth International Medical Congress at Moscow."

Dr. F. C. Cobb: "Acute Empyema of the Antrum of Highmore." Discussion by Drs. A. Coolidge, Jr., and J. P. Clark. JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION.—The Surgical Section will meet at the Medical Library, 19 Boylston Place on Wednesday evening, November 3d, at 8 o'clock.

The evening will be devoted to a consideration of "The Treatment of Tubercular Disease of Bones," as follows:

- (a) "The Pathology of the Disease in its Relation to Treatment," Dr. E. H. Nichols.
- (b) "The Operative Treatment," Dr. A. T. Cabot.
- (c) "The Non-operative Treatment," Dr. E. H. Bradford.

The presentation of specimens, apparatus, etc., of surgical interest is invited.

PAUL THORNDIKE, M.D., Secretary, 244 Marlborough St.

THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.—The address of the Secretary of this Association, Dr. James E. Pilcher, of the Army, has been changed from Columbus, O., to Fort Crook, Neb.

RECENT DEATHS.

JAMES SIMPSON, M.D., a prominent physician of San Francisco, Cal., died on October 22d, of pneumonia, aged seventy-one. Dr. Simpson was born in Calais, Me., in 1827. After his graduation from New York University, he entered the University of Edinburgh. After taking his degree he returned to Maine, and in 1852 went to San Francisco, where he settled after a period of practice in one of the California mining towns. He had served as president of the State Board of Health of California.

PROF. RUDOLPHE PIERRE HENRI HEIDENHAIN, incumbent of the Chair of Physiology at the University of Breslau, is dead. He was born in Marienwerder in 1834, and studied medicine and natural science at the Universities of Königsberg, Halle and Berlin, and experimental physiology under the direction of Professor Du Bois-Reymond.

THE INSANE POOR IN PRIVATE DWELLINGS IN MASSACHUSETTS.¹

BY SIR ARTHUR MITCHELL, K.C.B., M.D., LL.D.,
Ex-Commissioner in Lunacy of Scotland.

THE boarding out of the insane poor began in Massachusetts in August, 1885, under the provisions of an Act approved in that year.

The number of patients boarded out on the 30th of September of each of the eleven years 1886 to 1896 is as follows:

September 30, 1886	34
" 30, 1887	73
" 30, 1888	80
" 30, 1889	110
" 30, 1890	148
" 30, 1891	155
" 30, 1892	175
" 30, 1893	164
" 30, 1894	158
" 30, 1895	142
" 30, 1896	129

These figures show a slow but steady growth of the number of the boarded-out during the first seven years, but during the last four years there is a steady decline, though it is said that there has been "the same effort to place patients out." According to the Report, "the lack of material alone has prevented the advance of the system." There is room, however, for doubting the accuracy of this opinion. Other causes of failure have been in operation, and these must be considered in forming an estimate of the result of the experiment, which, as the Report says, we may fairly expect to be able to do from a knowledge of what has happened during the eleven years of its working.

The experiment has never been on anything but a quite insignificant scale; and this Report, in trying to form an estimate of its result, discloses many things which, to one long acquainted with boarding-out on a large scale in Scotland, seem to account for its having been a failure from the beginning. It is not in the light of the declining figures of the last four years that the experiment is regarded as a failure, because the slow growth of the first seven years quite as emphatically marks it as a failure. It may do good, and it cannot do harm, if a Scottish Ex-Commissioner in Lunacy, who is known to have given much attention to the question of boarding-out, makes a running comment on sixteen points in the Report, which seem to him to call for remark. Perhaps this can best be done by appending observations to short extracts from the Report. In order to make the reading easy the extract or extracts relating to each point, with a short heading, will be indented, and the remarks will immediately follow.

Difficulties in the way of the success of the experiment were to be looked for—were, indeed, inevitable; but it seems justifiable, as a general remark, to say that sometimes difficulties appear to have been created, and that at other times difficulties have been greatly magnified. As another general remark, it may be said that there has been a misunderstanding of the real purpose of the system, and this will be shown in the observations which follow.

A most important disclosure of the Report is that

¹ Remarks on what is said regarding the boarded-out insane in the Eighteenth Annual Report of the State Board of Lunacy and Charity, January, 1897.

the number of persons who desire to receive boarders is in excess of the supply. The inference is that there is no scarcity of guardians; and as it will be seen from what follows that it is regarded as plain that the views which have regulated the supply should be altered, there is no reason why the boarding-out of the insane poor in Massachusetts may not yet be a great success.

As regards lunatics in almshouses the need of fresh legislation is very plain and very urgent.

I. MENTAL AND BODILY CONDITION OF PATIENTS PLACED IN PRIVATE DWELLINGS.

(1) "Persons of the quiet and chronic class."

Page 84.

(2) "Chronic cases of good physical health and quiet and tidy habits." Page 85.

(3) "Entirely tractable." Page 86.

(4) "Simply requiring to be comfortably clothed, housed and fed." Page 86.

In Scotland patients provided for in private dwellings are certified to be (1) incurable, (2) harmless, and (3) not in need of such special nursing as cannot easily be found out of institutions. This is regarded as enough. As a permanent provision is contemplated, incurability is assumed to be a feature of the patient's condition. Of course, patients may sometimes be erroneously certified to be incurable, and recoveries among them may therefore occur. Transferences from asylum care to private care, made for the purpose of completing or confirming convalescence, are not regarded as a mode of providing for the insane, but as a means of treatment; they are of a temporary character and are called *Liberations on Probation*.

II. ADVANTAGES TO PATIENTS OF CARE IN PRIVATE DWELLINGS.

(1) The "patient enjoys home comforts and pleasures, and a measurable return to his former habits of life." Page 85.

(2) "The flickering remnants of mental activity are stimulated by the presence of old familiar habits, and the patient is happier than in the hospital." Page 85.

This accords exactly with forty years' Scottish experience. If it is true of any single patient that his happiness and enjoyment can be thus increased, the State has no right to deprive him of that blessing, even if it cost a little more, instead of a good deal less. *Admittedly*, some lunatics do enjoy life more out of asylums than in them—in their old familiar roughish environments than in the great formal day-rooms and dormitories of a public institution, with the irksome discipline and methods which must, and always do exist there. If there are, as is *admitted*, some patients who can be thus benefited, it becomes a duty to ascertain how many there are, and, with that in view, to ask ourselves whether long connection with asylums does not tend to make us bad judges of what patients among the incurable could with advantage live under private care in natural non-institutional surroundings.

III. CHARACTER OF FAMILIES IN WHICH PATIENTS SHOULD BE PLACED AND ASYLUM TRAINING OF GUARDIANS.

(1) "In families without young children, and one or both of whose heads have had hospital training." Page 85.

(2) "In families in which 'enough of the hospital system appears to help ordinary family government.'" Page 85.

In the experience of Scotland the presence of young children in the homes of the guardians is often a decided advantage to the patients. It is a common experience to find a boarded-out lunatic an excellent and trustworthy nurse.

Asylum-trained guardians do not ordinarily prove so satisfactory as persons who have no special training, but who have shown good common-sense and kind-heartedness in their relations to their children, relatives and neighbors. There is nothing which is so much disliked in Scotland as the appearance in the homes of the boarded-out of any trace of asylum methods of management. Every effort is made to render the life of such patients a true home and family life—the patients being as nearly as possible members of the family in which they live. This is generally found to be quite possible; and the patients share the interests, the pleasures and the sorrows of their guardians.

IV. DIFFICULTY IN SECURING WITHOUT DELAY IN CASE OF ILLNESS THE CARE WHICH CAN BE AT ONCE OBTAINED IN ASYLUMS.

(1) There is a "difficulty of securing in case of illness the same care that can be obtained without the slightest delay in the hospital." Page 88.

It is difficult to believe that this is seriously advanced as an obstacle in the way of boarding-out suitable patients.

The *care* referred to is evidently medical care. The guardians may fall ill as well as the boarders, and there would be no greater difficulty in obtaining the attention of a medical man in the one event than in the other. It is no hardship that the guardians and patients should be on an equality in this matter. A residence would not, of course, be chosen because it was far from a doctor, nor, when such a residence was selected as in many respects suitable, would a specially delicate patient be placed in it; but, in a general sense, there is nothing in the condition of suitable patients to prevent their living in the circumstances in which people of their class usually live.

V. RISK OF GUARDIANS DOING THEIR WORK FOR THE SAKE OF GAIN.

(1) There is a risk that persons will "take patients for the sake of gain." Page 86.

(2) In agreeing to receive boarders "the motive of personal gain necessarily exists to some extent." Page 87.

No one could have expected that persons would receive insane boarders into their families without the hope of some advantage from doing so. Indeed, they ought not to do so without that hope. They ought to be sufficiently remunerated. Proper payment tends to secure good work in this as in other things. It is not a work of charity, though kindness should appear in it, and be required. The word *gain* has associations which give it an unpleasant ring; but the motive of gain or advantage is quite a proper motive, and in good administration there is no difficulty in preventing abuses and excessive gains.

VI. RISKS TO THE YOUNG PERSONS FROM ASSOCIATION WITH THE INSANE.

(1) "The companionship of a person afflicted with insanity is extremely unsuitable for young and unformed minds, and is sometimes even attended with dangerous results." Page 86.

(2) "The influence on children is far from good." Page 89.

No evidence of such injurious influence has presented itself in Scotland. It must be remembered that the insane, who are under private care, are believed to be incurable and harmless, and are often feeble in body as well as in mind. They are objects of sympathy, and the young, as well as the old, are led to treat them with kindness and consideration. In this direction there is an educational advantage to the young from having two or three imbeciles boarded in a village, in whose well-being the State shows an active and kindly interest. The real nature of the sad condition of such persons comes to be understood, and sentiments like the following become more common:

"An is there ane amang ye, but your best wi' them wad share? Ye mauna scaith the feckless, they're God's peculiar care."

It is difficult to disprove an assertion like that contained in these quotations. It is mere assertion, however, and on its side is unsupported by proof; and, so far as the experience of forty years' work in Scotland goes, there is no evidence of any such injury to the young.

VII. THE RISK OF OVERWORKING PATIENTS IN PRIVATE DWELLINGS.

(1) There is a "danger that too much work may be imposed" on them. Page 87.

(2) There is a risk of the "imposition of tasks too severe for strength." Page 87.

Of course, such a danger must exist. The risk, however, is not great. And it will not be difficult under a good administration to make arrangements which will render the risk exceedingly small. The existence of this, as of any other risk, ought not to be ignored, but it will not be found to be of such magnitude as to constitute any obstacle to the development of the system of boarding-out the incurable and harmless insane poor with guardians or care-takers selected from the people either of New England or of Old Scotland.

VIII. PATIENTS IN FAMILIES LOSE THE AMUSEMENTS OF PATIENTS IN ASYLUMS.

(1) "Patients in families are necessarily deprived of almost all the advantages of social life, the amusements and entertainments which form so large a feature of the ordinary hospital routine." Page 87.

The dances, theatrical performances, concerts, and games of asylum life become proper, or rather necessary, as a relief to the dull monotony and *routine* of that life, and are needed for patients, officers and attendants alike. But going back to family life is a going back to true social pleasures and enjoyments. These are longed for by asylum inmates just in proportion to the power they have of longing for anything. No sane person would exchange them for asylum dances and concerts. The thousand and one familiar things constantly going on around patients in families constitute a far greater source of enjoyment than the scenic and got-up entertainments of asylums, and fill their lives with truer delights. Of course, all this involves the ability to give to boarded-out patients a life closely approaching to real family life, that is, the ability to place them with guardians or care-takers who will make them as far as possible members of their families. That this is possible has been abun-

dantly proved, and the happiness of many of the insane poor has in that way been much increased.

IX. PRIVATE CARE BEST SUITED FOR CONVALESCENTS.

(1) Care in private dwellings "seems to apply most happily to those who are on the road to recovery"; they are "convalescent homes for them"; "several patients entirely recovered in this way, whose recovery would have been doubtful, or very much delayed, had they remained in the hospital." Page 88.

(2) "Convalescent cases receive the most benefit" under private care; "for them the system is best suited." Page 89.

There is a complete misunderstanding here of what is properly enough called the *system* of boarding-out. It is a method of providing for the care of the incurable and harmless, and it concerns itself with arrangements and conditions which are expected to be lasting.

Of course, recoveries are often hastened and confirmed by removing patients, who are improving, from asylums to care in their own homes or in the homes of persons not related to them, and every good Lunacy Law should make it easy to liberate patients on probation for some definite period with this good end in view.

But it is an altogether different feature of the lunacy administration of a country which proposes to provide for a considerable number of harmless and incurable lunatics in private dwellings, instead of leaving them in asylums.

The number of pauper lunatics in Scotland satisfactorily provided for in private dwellings is 23 per cent. of all the pauper lunatics in the country. Scotland is nearly twice as populous as Massachusetts, and the proportion of the insane to the population is nearly the same.

In further reference to this point, it seems proper to ask whether convalescent insane patients are more fit than others to be exposed to the risks of being under the care of persons without hospital training, of being without the means of instantly having a doctor, of being kept for gain, of being overworked, etc., and also, whether they would not injure young persons associating with them, and would not suffer from the loss of hospital entertainments and hospital social life.

X. STRAIN ON GUARDIANS OF ATTENDANCE ON PATIENTS BOARDED WITH THEM.

(1) The guardians or care-takers may tire "of the strain which this constant and unremitting attendance occasions." Page 86.

(2) "They can never leave home together without first securing some reliable neighbor to take charge in their absence." Page 86.

If suitable patients are selected for care in private dwellings there will not be any such "constant and unremitting attendance" as to cause any strain which will be a subject of complaint. It may be otherwise, of course, if the patients are badly chosen. The presence of an insane member in a family, will no doubt sometimes — perhaps often — make it as difficult for both guardians, if there are two, or for the single guardian, if there is only one, to leave home as if there were young children in the family. But it will not be more difficult, and the parents of children, if they are sensible and respectable people, do not

complain of having to keep at home, or of their not being as free to move about as if there were no children under their care.

XI. WOMEN SHRINK FROM ASSOCIATION WITH PERSONS OF IMPAIRED INTELLECT.

(1) "Most women shrink from near association with persons of impaired intellect." Page 89.

This is a very surprising statement. It is not true of the women of Scotland. They are as capable and fearless as they are kind, in nursing persons of impaired intellect. They often devote themselves most lovingly and intelligently to the care of a helpless imbecile or dement.

It is not easy to believe that what is said here of Scottish women could not be said with as much truth of the women of Massachusetts.

XII. THE DEMAND FOR INSANE BOARDERS EXCEEDS THE SUPPLY.

(1) It is "a significant fact that the demand for insane boarders invariably exceeds the supply." Page 81.

(2) The "demand for patients is always greater than the supply." Page 89.

These are most important statements, and show the possibility of making care in private dwellings a part of any whole scheme for providing for the insane poor, if well-directed efforts are earnestly and continuously made. This, of course, assumes that the proportion of incurable and harmless patients in the whole body of the insane poor does not differ radically from the proportion in Scotland; and there is nothing to show that any such difference exists.

XIII. BOARDING-OUT IS OBJECTIONABLE AS LEADING TO THE REMOVAL FROM ASYLUMS OF USEFUL AND PROFITABLE WORKERS.

(1) "The boarded-out are those easiest to care for in the hospital." Page 88.

(2) "The number of paid employees in our hospitals is so small that much of the work must be done by patients with the result not only of considerable saving to the State, but of being a wise adjunct to the treatment of the patients. Thus the greatest number eligible for boarding-out are either quiet patients, doing no work, and requiring the minimum of hospital care, or else chronic cases, helpful to themselves and others, whose departure reduces the working force of the hospital." Page 88.

This view of the question is full of error. On the threshold it ignores the obligation of the State to do for the insane poor what is best for them, and to make their life as happy as it can be made. As regards a certain number of them — not inconsiderable — it may be safely said that every person, having special experience in the care of the insane, holds that they are happier out of, than in, asylums. All physicians act on that view, and so do all laymen. Every insane person is not sent to an asylum. Only those are sent, who, in addition to being insane, require care and treatment in institutions. It is recognized on all hands that it would not be right to subject some insane persons to the loss of liberty and the irksome discipline which asylum life necessarily involves. If then it is not right to send to asylums persons in certain states of insanity, it is clearly wrong to continue to detain persons in asylums, who, after a longer or shorter

residence there, have passed into corresponding states of insanity. Whatever the number of these persons is — whether it is large or small — they ought not to be kept in asylums when they have ceased to need such detention, and when they can be provided for otherwise, in a way which adds to their happiness. This should be a guiding view in State lunacy administration, even if the other way of providing for such persons led to some increase of cost. But it so happens that it diminishes cost and leads to saving.

It is not easy to believe that any one would seriously hold that it was right to keep persons in an asylum because they worked well and profitably — were good laundresses, were useful in the kitchen, gardened well, were good musicians, or were serviceable in other ways. This would be almost equivalent to holding that it would be proper to detain patients unnecessarily in asylums for gain to the asylum authorities, that is, for gain to the State.

But it is desirable to point out that the removal of quiet patients who are good workers, and are able to be helpful to themselves and others, has not the effects which it is here alleged to have. This has been abundantly proved. When such patients are removed, this is what happens: it is found that there are other patients who can be induced to work. The set of good workers being sufficient in number, no serious effort is made to lead non-workers to become workers. They are not wanted, and a refusal to work is too easily accepted as a thing that cannot be got over.

In this way the removal of the incurable and harmless does good to those who are left, and tends to increase the number of recoveries.

XIV. OVERSEERS OF THE POOR HINDER THE GROWTH OF THE SYSTEM OF BOARDING-OUT.

(1) Before removing patients to private care the "consent of the overseers of the poor must first be obtained," and they "prefer to care for them in their own almshouses." This is "a serious obstacle to the success of the system." Page 89.

(2) During the year ending March 31, 1896, "86 persons were discharged to the overseers of the poor, most of whom were eligible for boarding in families." Page 89.

(3) "Were small towns forbidden by law to make their almshouses receptacles for the insane, the number of those boarded-out would be largely increased." Page 89.

All this points to the necessity of fresh legislation.

(1) All the insane poor, *however provided for*, should be as much under the care of the State as those of them who are in asylums.

(2) No almshouse should be allowed to receive insane inmates, which is not licensed to do so by some State authority — the license being granted on well-considered conditions.

XV. MODES OF PAYMENT FOR THE INMATES OF ALMSHOUSES.

(1) Of one almshouse it is reported that "whatever is saved from the weekly allowance of two and one-half dollars for each inmate is allowed to the warden and matron for their services." Page 97.

(2) "It is certainly not to the credit of the State that a town should sell its unfortunate poor at public auction to the lowest bidder at the annual town meeting." Page 96.

(3) Some means should be devised to abolish "the practice of placing their poor in the family offering to support them at the lowest price." Page 96.

(4) "In one instance a town actually receives twenty-five dollars from an individual for the privilege of boarding one feeble-minded woman who renders valuable service." Page 95.

(5) "One of our cities maintains its poor at its almshouse by allowing the warden a certain sum per capita per week, his salary being what he is able to save from this amount." Page 96.

These things appear in an official report, and must be accepted as true; but it is impossible to believe that they will not soon be things of the past in Massachusetts — things to be remembered with some shame, as well as with regret.

XVI. CONDITION OF INSANE INMATES OF ALMSHOUSES AS REGARDS RESTRAINT AND WANT OF COMFORT.

(1) "In many almshouses there are still to be found strong cages that were formerly used for the close confinement of insane inmates. These have almost wholly gone into disuse, and but a small number of cases are subject to restraint or confinement." Pages 173, 4.

(2) In one almshouse it is reported that "a room for the special care of troublesome insane women has been built in the wing." Page 123.

(3) Of another almshouse it is said that "an insane man has unattractive lodgings in an out-building." Page 139.

All this is most unwillingly received as true. It points to an urgent need of fresh lunacy legislation. It is out of harmony with all the good, as well as great, things done in New England.

XVII. DEFICIENT SEPARATION OF THE SEXES AND OF THE INSANE FROM THE SANE IN ALMSHOUSES.

(1) In 66 of the almshouses neither are the sexes separated, nor are the sane separated from the insane. And in 35 more there is no proper separation of the sexes. In many others, though there is a separation of the sexes, there is no separation of the insane from the sane. Pages 95-172.

This state of matters is referred to in the report as very unsatisfactory. It is said, with reference to the want of separation of the sexes, that "complications from this cause are not unknown"; that "evils from the defect are apparent"; that the separation of the sexes should be made complete "to avoid such unfortunate results as have followed from the present arrangement"; and emphasis is laid upon the necessity both of separating the sexes, and of separating the insane from the sane (Page 95). It is difficult to understand how far the want of separation of the sexes goes, but it clearly goes to an extent which is undesirable and wrong.

ENGLISH GEOGRAPHY. — A recent number of an English medical journal, in quoting a paper read before a Western medical conference, says it was read at Indianapolis, INDIA.

PROPHYLAXIS CHEAPER THAN CURE. — "It costs two hundred dollars to have a frozen toe amputated in Alaska." — "Well, if you go, you would better have yours cut off before you start." — (*Chicago Record*).

THE PUBLIC CARE OF THE INSANE IN MASSACHUSETTS.¹

BY J. L. HILDRETH, M.D., CAMBRIDGE, MASS.,

Professor of Clinical Medicine, Tufts Medical School; Member of State Board of Lunacy and Charity, etc.

AN eminent authority has divided the history of the treatment of insanity into three periods, — the barbaric, the humane and the remedial. It is to the credit of our profession in Massachusetts that we were early in the field in humane treatment, and that at the present time we are among the foremost in remedial treatment. A brief preliminary survey of the progress made in England and on the Continent may fit us to better appreciate our own relative position.

Although we read of an insane hospital founded by monks at Jerusalem in the sixth century, of shrines to which the insane resorted for healing in the seventh century, of asylums established in Mohammedan countries at intervals all through the Middle Ages, of an asylum founded in Utrecht during the fifteenth century, and of four others in Spain at the same period, we are not to suppose that any of these were asylums in our modern use of the word. In most cases they were under the care of monks, whose treatment was aimed at the punishment of sin rather than at the healing of sickness. "The Franciscans," says a careful writer, "used to whip daily those under their charge, and it would be idle to guess how many were burned, put to the rack, etc., under the theory of witchcraft and devilcraft."

The well-known "Bedlam" of London, one of the oldest existing insane hospitals, was originally a monastery of the order of Bethlehem, whence its name ("Beth-le-hem," corrupted in the popular speech to "Bedlam"). When that much-married monarch Henry the Eighth took upon himself to suppress the religious houses in England, he was pleased to convert this into an asylum, filling it, as he said, "with another set of crazy folks." It accommodated at this time some fifty or sixty patients, and yet it was not until nearly a hundred years later that it was able to boast a single medical attendant. Doubtless it was as well managed as any similar institution of its day. Yet its revenues were so scanty that the practice of allowing partially convalescent patients to wander about the streets, with badges affixed to their arms, begging in its behalf, was not abandoned until the middle of the seventeenth century. Another money-making method, more shocking still to the sensibilities of our day, is described by Francis Tiffany, in his sketch of the asylums of modern Europe. "Up to so late a date as 1770," says Mr. Tiffany, "this famous hospital was still regarded as the raree-show of the city, superior even, in the attractions it offered the pleasure-seeker, to a bull-baiting or a dog-fight. No more diverting entertainment could be devised by the average citizen for guests visiting him from the country than to take them, for a hearty laugh, to Bedlam, to see the madmen cursing, raving and fighting. There was to be had on show St. Paul or Julius Caesar chained to the wall, or Semiramis or Joan of Arc ironed to the floor; while the general throng, left more at liberty, were guarded by brutal keepers, ready on the slightest provocation to knock them senseless with heavy clubs. The annual fees derived from this public entertainment amounted to several hundred pounds.

No one seems to have felt any pity for these poor wretches. The abyss which opened up between them and ordinary humanity was too wide and deep for any sympathetic imagination to span. A madhouse was a menagerie, nothing more, and it was as legitimate to look through the bars at one class of wild beasts as at another."

At the close of the last century there were only five public asylums in all England, and but very few private ones. The methods employed in the best of them may be judged from the fact that Willis, a specialist of such reputation as to be entrusted with the treatment of his Majesty George the Third, allowed his attendants to beat unruly patients at their discretion. Aside from the small number gathered in the asylums, the insane roamed at their will over the country — as if King Lear and Ophelia were always at large — or were confined in houses of detention, as a measure of public safety. These were but prison-houses, where the chain and lash, with slow starvation, were the methods most relied upon.

In other European countries things were no better. Hiring out the insane to farmers and peasants was not an uncommon practice. We read of a Scottish farmer, "as large as Hercules," who had a reputation for curing them by his severity. The first German insane asylum was not established till 1784. In the French asylums whipping was regularly allowed, — a practice whose horrors we do not fully appreciate until we learn that the attendants were often convicts serving out their time. One remedy much favored was the sudden plunging of the patient into cold water. But by "remedy" and "cure" we are not to understand anything like what is meant in our use of these terms. Indeed, a large part of the miseries which the insane have suffered, within modern times, have been due to the belief that their malady was the result of wilful sin, and was incurable. "God only knows," wrote a German scientist of high reputation, at the beginning of our own century, "whether an insane person can be cured or not."

Such being the beliefs and practices prevailing in the mother countries, it was not strange that the American colonists — poor, scattered, and in daily peril, and with all the complex machinery of a new civil life to set in motion — should have given but little thought to the needs of this despised class. In our own Massachusetts colony — according to Dr. Samuel Green, to whom I am much indebted for information concerning this period — the earliest legislation relating to them is an enactment of the General Court in 1676, at the time of King Philip's War. It has been suggested that the horrors of that war — in which it is estimated that one man in every eleven was killed, and one family in every eleven burned out of house and home — may have added to the number of the insane, and thus brought their condition to public notice. The enactment reads as follows:

"Whereas there are distracted persons in some towns that are Unruly, whereby not only the Families wherein they are, but others suffer much danger by them. It is ordered by this Court and the Authority thereof: That the Select men in all Towns where such persons are, are hereby Impowered and Injoynd to take Care of all such persons that they do not Damnify others, And also to take care and Order the Management of their estates in the time of their Distemperature, so as may be for the good of themselves and Families depending on them: and the Charge to be paid of the Estate of all such persons where it

¹ Delivered before the Middlesex South District Medical Society at its annual meeting, April 21, 1897.

may be had, otherwise at the publick Charge of the Town such persons belong unto."

Private diaries and newspapers of the period contain records of individual cases of what would now be regarded as insanity, although it was then explained as "possession of the Evil One." Doubtless many of the phenomena of the notorious "Witchcraft Delusion" of Salem would in our time be attributed to insanity. Twenty years before that period, the Rev. Samuel Willard, a minister of Groton, writes of a young girl of his town whose case was creating considerable excitement there. At the outset it baffled the skill of the neighbors, who were inclined to think her possessed of the Devil; and the minister was called in, who talked with her and prayed with her, but all to no purpose. A physician was sent for next, "who judged a main point of her distemper to be naturall, arising from the foulness of her stomache and corruptness of her blood, occasioning fumes in her braine, and strange fansyes." Finally, the poor girl confessed that she had made a covenant with the Evil One, and her actions were so strange that the doctor was nonplussed and gave up the case. He then "consented that the distemper was Diabolical, refused further to administer, and advised to extraordinary fasting." A council of ministers was convened to consider the matter, but they did not help her. She afterward declared that she had signed a league with his black majesty in her own blood. It is not recorded what became of this patient finally; but if she had been seized with the same symptoms twenty years later, there is little doubt that she would have been tried as a witch and hanged.

Chief Justice Sewall, in his Diary, under date of March 11, 1685-86, speaks of a "crazed woman" who created a panic in the Old Meeting-House, Boston, just before the Thursday lecture, when the building was crowded, by crying that the gallery was coming down. He then goes on to say:

"I know not whether the mad woman said the house fell, or whether her beating women made them scream, and so those afar off, not knowing the cause, took it to be that; but the effect was as before, and I was told by several as I went along, that one Gallery in the old Meeting-house was broken down. The mad woman was the Daughter of Goodman Bishop, Master of Morgan. She went in at the South-west door, beat the women, they fled from her! those above supposed they fled from under the falling Gallery."

Another early instance of insanity is found in "Public Occurrences, both Foreign and Domestic," Boston, September 25, 1690, the first newspaper printed on this continent. Without doubt the case was one of melancholia, and the account of it is as follows:

"A very Tragical Accident happened at Watertown, the beginning of this Month, an Old Man, that was of somewhat a Silent and Morose Temper, but one that had long Enjoyed the reputation of a Sober and a Pious man, having newly buried his Wife, the Devil took advantage of the Melancholy which he therefore fell into, his Wives discretion and industry had long been the support of his family, and he seemed harried by an impertinent fear that he should now come to want before he dyed, though he had very careful friends to look after him who kept a strick eye upon him, least he should do himself any harm. But one evening escaping from them into the Cow house, they there quickly following him found him hanging by a rope, which they had used to tie their Calves withal, he was dead with his feet near touching the ground."

Among the charitable contributions made by the

town of Chelmsford during the last century, appears this item:

"For Joseph Chamberlain, whose wife and son are at Groton distracted: May 10, 1752 was collected lawful money, 38l 2s 0d."

Evidently the sense of public responsibility for the care of the insane was on the increase. At about this time, in 1751, in the sister colony of Pennsylvania, the legislature received a petition praying its aid in founding a small hospital for the insane, and for other persons laboring under disease, on the ground that "some of them going at large are a terror to their neighbors, who are daily apprehensive of the violence they may commit, and others are continually wasting their substance, to the great injury of themselves and families, ill-disposed persons wickedly taking advantage of their unhappy condition, and drawing them into unreasonable bargains, — that few of them are so sensible of their condition as to submit voluntarily to the treatment their respective cases require, and therefore continue in the same deplorable state during their lives." The necessary act was passed, a sum of money was voted, conditioned on the raising of an equal amount by private means, and the new hospital was opened at Philadelphia in the following year.

In 1773 an asylum, notable as being the first founded for insane patients exclusively, was established by the State of Virginia at Williamsburg.

In the same year was begun, by private subscription, the building of a general hospital in New York, which was interrupted, first by fire, and then by the disturbances of the Revolutionary period. It was completed in 1791, and in 1797 two cases of mania were admitted. In that same year the "Maryland Hospital" was established in Baltimore for general diseases and insanity.

There were thus, at the beginning of the century, in the whole country, only four institutions of a public character where the insane were cared for — none of them in Massachusetts — and of these four only one had been built for the care of the insane, entirely with public funds. "Private institutions," says a distinguished authority — Dr. Charles F. Folsom — "were almost entirely unknown, and the few that existed were only better than the jails and poorhouses, where many of the insane were kept." Pitiable as this state of things seems, it is interesting to note the comment of Dr. D. Hack Tuke, Fellow of the Royal College of Physicians, London, that in America "the care and treatment of the insane were probably neither better nor worse than in the mother countries from which the early settlers came." Indeed, as to England, the first commission to look after pauper lunatics was not appointed till 1828, and then for London only. Up to that time the only act in force was one by which any two judges might cause them to be apprehended, locked up in some secure place, "and there chained." The parliamentary investigations of the years previous to the appointment of this pauper commission had revealed startling facts. In one asylum there was found to be but a single towel for the use of the one hundred and seventy patients. At Fonthill, thirteen out of fourteen patients were in chains or handcuffs. At Bethnal Green — an institution where five hundred were accommodated — there was no physician or surgeon in charge, but an apothecary made two or three visits each week. It was a common practice there to

chain patients to their cribs, and confine them from Saturday evening till Monday morning, to give the attendants a Sunday holiday.

But in all civilized countries a new epoch was dawning—"an epoch," says Tiffany, "as revolutionary within this especial realm as that of the Copernican system in the realm of astronomy. It implied an absolute reversal of all previous conceptions; the substitution, in the place of restraint and force, of the largest possible degree of liberty; the abandonment of the whole previous idea of brute subjection for that of the emancipation of the reason and the enhancement of the sense of personal responsibility." Two remarkable men, Philippe Pinel in France, and William Tuke in England, were the pioneers in the movement. Amid the horrors of the French Revolution, Pinel, the newly appointed superintendent of the asylum for incurables, appealed to the Commune for authority to set part of his patients free from their chains. The project seemed visionary and impracticable to the last degree. A deputy went with Pinel to the asylum. They were greeted by the yells and hootings of three hundred maniacs, "mingling the clanking of their chains with the uproar of their voices." "Are you mad yourself, Citizen," asked the deputy, "that you would unchain such beasts"? But Pinel's ardor triumphed; and within three days fifty patients were unchained, and with results such as fully justified the experiment.

Independently of Pinel, but along the same lines, the Society of Friends was working in England, under the leadership of William Tuke, not a physician, but a man of ample means and large benevolence.

The impulse of these reforms was soon felt in the United States. The first quarter of the century saw the establishment of a number of private and public asylums. That of the Friends at Frankford, Pa., modelled after Tuke's Retreat at York, was founded in 1817; our own McLean Asylum in 1818; the Bloomingdale Asylum in 1821; the Hartford Retreat in 1824; and the Columbia Asylum in South Carolina in 1827.

Turning now to the history of our own State exclusively, it may fairly be said that the first public care of the insane dates from October, 1818, when the McLean Hospital was opened in Charlestown, as one of the two departments of the Massachusetts General Hospital. By the end of the year it had nine patients. At that time both departments were governed, as they are now, by the same Board of Trustees, four of them appointed by the Governor and Council. The number of patients admitted during the first year of its existence was fifty-eight. The hospital, when it was founded, was assisted by appropriations from the State, and at that time a certain proportion of the inmates were a public charge. A few years later these were transferred to the State hospitals, and since then no State patients have been treated at the McLean Asylum; nor has the State made any contribution to, or in any way assisted it. But the continuing representation of the State upon its governing board makes it still, in a sense, one of our State institutions. Of its founding, Dr. Folsom writes: "It marks an important era in the history of mental disease in this country. It established the character and principles of treatment which have become universal among us, and especially the principle of State supervision. The trustees were men of broad views and high character. In nearly

eighty years (to 1897) their faithful and careful weekly visits to the asylum were only twice omitted. In advance of the usual practice of the time, too, a resident medical superintendent was appointed." This superintendent, Dr. Rufus Wyman, was a man of much learning, and, as has been justly remarked, one more than half a century beyond his day in regard to the care and treatment of the insane.

The opening of the State Hospital at Worcester, in 1833, was in some respects a still more notable event. Up to that time no State, with the single exception of Virginia, had attempted to do more than give assistance to private efforts in behalf of the insane. But the responsibility for the erection and maintenance of the Worcester Hospital was entirely assumed by the State, although voluntary contributions from various sources were received at the outset, the town of Worcester giving \$25,000 for the purchase of the site. Horace Mann was a leader in this enterprise; and his principle, that "the insane are the wards of the State," has now become a guiding one among all civilized nations.

What in the light of modern theory and experiment we may call the rational treatment of irrational patients was now fairly begun. The new humanitarian movement was given a great impetus by the efforts of four Massachusetts physicians.—Dr. Rufus Wyman and Dr. Luther V. Bell of the McLean Hospital, Dr. Samuel B. Woodward of Worcester, and Dr. John S. Butler of Boston. The attainments of men such as these commanded recognition abroad, as well as at home. Our collection of the social and vital statistics of insanity was on a par with that of any European country. An American work by Dr. Ray, on "The Medical Jurisprudence of Insanity," was admitted to be the first authority in any language. In respect to State asylums, our country was distinctly in advance of Europe, as was freely conceded by distinguished specialists who visited us.

But there was a dark side. Admirable as were our hospital methods, earnest as was the spirit of those in charge of them, the accommodations were utterly inadequate to the needs of our population. In 1843 the entire provision for the insane—in the State Hospital at Worcester, in the McLean Asylum, and in the Hospital at South Boston—was scarcely sufficient for 500 patients, while there were within the State 958 pauper insane and idiotic persons, besides 800 more maintained at private charge. Several hundred of the State's poor were thus left to the shelter of town or county poorhouses and jails, where the beliefs and practices belonging to the old era of barbarism were still lingering. To seek them out was work waiting for a philanthropist.

From the standpoint of philanthropy, the most important period in the care of the insane in Massachusetts is the decade following 1840. The alleviation of human suffering is especially the province of woman, and the providential instrument to begin the reform of the abuses to which insane paupers were then subjected was a woman.—Dorothea L. Dix, God's angel of mercy to all suffering from mental disorder throughout our land and the whole civilized world.

It is strange that the jail whose loathsomeness first attracted her attention should have been found in the very city which boasts itself as the seat of Harvard College. Our learned professors had been busy with their Greek, and no doubt could have discoursed most

edifyingly on the rites in the temples of Æsculapius; but it seems never to have occurred to them that the treatment of the insane in those classic days was probably much more humane than that which nineteenth-century Cambridge was providing for her unfortunates.

It was but a trifling incident, humanly speaking, which led Miss Dix to begin her investigations. She was asked by a young divinity student—Rev. J. T. G. Nichols, afterwards a minister at Saco, Maine—to assist him in his Sunday afternoon work at the East Cambridge House of Correction. Upon her first visit she noticed among the prisoners a few insane persons, and was surprised to observe that there was no stove in their room, nor any other means of proper warmth. The jailer explained that they did not need a fire, and that it would be unsafe for them to have one. "Her repeated solicitations," writes Mr. Nichols, "were without success. At that time the court was in session at East Cambridge, and she caused the case to be brought before it. Her request was granted. The cold rooms were warmed. Thus was her great work commenced."

Cold was the least of the evils brought to light by the efforts of this large-hearted and resolute woman. Far more shocking was the filth, the overcrowding, and the promiscuous herding together of innocent and guilty, sane and insane. Miss Dix's exposure of these conditions led to much newspaper controversy in the months that followed, in which she was supported by such men as Samuel G. Howe and Charles Sumner, who had made visits of personal inspection at her request. I quote from a letter of Sumner to Howe:

MY DEAR HOWE,—I am sorry to say that your letter does present a true picture of the condition in which we found those unfortunates. They were cramped together in rooms poorly ventilated, and noisome with filth. . . . You cannot forget the small room in which were confined the raving maniac, from whom long since reason had fled, never to return; and that interesting young woman, whose mind was so slightly obscured that it seemed as if, in a moment, even while we were looking on, the cloud would pass away. In two cages or pens constructed of plank, within the four stone walls of the same room, these two persons had spent several months. The whole prison echoed with the blasphemies of the poor old woman, while her young and gentle fellow in suffering, doomed to pass her days and nights in such close confinement with her, seemed to shrink from her words as from blows. And well she might, for they were not to be heard by any woman in whom reason had left any vestige of its former presence. It was a punishment by a cruel man in heathen days to tie the living to the dead; hardly less horrid was this scene in the prison at Cambridge. Ever faithfully yours,

CHARLES SUMNER.

For the next two years Miss Dix made it her business to find out whether the condition of things in Cambridge was exceptional, or whether something like it prevailed throughout the State. Note-book in hand, she visited every jail and almshouse in Massachusetts. On the mass of evidence thus collected—the evidence of an eye-witness—was based the Memorial which she addressed to the Legislature in January, 1845.

This remarkable address occupies 32 pages of the Public Documents. It is made up largely of extracts from her note-book,—the simple facts being left to tell their own tale, with little help of rhetoric. At the Northampton jail was a young man, violently mad,

who had come under no medical care and had been in no asylum. At the Burlington almshouse, an insane man in bed to save trouble, not allowed to rise oftener than every other day. At Lincoln, a woman in a cage. At Medford, a subject who had been in a close stall for seventeen years. At Bridgewater, three idiots, never removed from one room. At Pepperell, a man doubly chained, band and foot. At Granville, one losing the use of his limbs for want of exercise. At Saugus, a woman sitting on the floor, with limbs immovably contracted, so that the knees were brought up to the chin, the result of neglect and exposure. This woman's bed, "so-called, was about three feet long, and from a half to three-quarters of a yard wide; of old ticking or tow-cloth was the case; the contents might have been a full handful of straw or hay." At Newburyport, was a woman confined for years in a cellar, in a closet beneath the stairs, absolutely unlighted and unventilated. At Ipswich, a simple-minded girl, confined in an out-building with two insane men, one violently mad, their stalls not so much separated as to secure decency. At Wayland, caged in a woodshed, fully exposed upon the public road, a man who was partially clothed at the time Miss Dix visited him, but of whom his keeper reported that he was "more likely to be naked than not." Want of accommodations for the imperative calls of nature had converted the cage into a place of offence; he was said to be "cleaned out once a week." His limbs were so affected by confinement and cold that he was often powerless to rise. At Groton, in a solitary outbuilding, unlighted except when the weather allowed the door to be thrown open, was a young man chained by a heavy iron collar. At Westford, in a room of the almshouse, a young woman entirely naked but for portions of a blanket. She begged for clothes but was refused; pointed to the iron chain about her waist and said mockingly, "See there! nice clothes." At Fitchburg, in an outbuilding, utterly dark and furnished only with straw, a man whose look, "though feeble and sad, was calm and gentle," and who was sane enough to beg most pitifully for some books which Miss Dix was carrying in her hand. On her replying, "You could not use them, my friend; you have no light here," he made answer in a voice lowered cautiously, "Oh, give them to me, do! I'll pick a little hole in the plank and let in some of God's light." On inquiring of his master whether he could not be allowed more liberty, she was informed that they were thinking of getting a chain and collar from the blacksmith, so that they could keep him outdoors.

To the miseries which these unfortunates suffered from lack of occupation, even when their physical condition was not made intolerable by privation and cruelty, Miss Dix often calls attention. Of the moral dangers to which they were exposed, she speaks with great plainness. "A few months ago," says the Memorial, "a young woman in a state of insanity was confined entirely naked in a pen or stall in a barn; there, unfurnished with clothes, without bed and fire, she was left—but not alone: profligate men and bad boys had access to the den, whenever curiosity or vulgarity prompted." In the same connection she refers to the case of a young woman, of decent life and respectable family, at the Worcester almshouse. "I have seen her as she usually appeared, listless and silent, almost or quite sunk into a state of dementia. A few weeks since, revisiting that almshouse, judge of my horror

and amazement to see her negligently bearing in her arms a young infant, of which I was told she was the unconscious parent! Who was the father, none could or would declare."

Miss Dix points out that not the victims only, but the whole community, are corrupted by these horrors. Of her visit to Sudbury, she says: "Approaching, as I supposed, the poor-farm there, the terrible screams and imprecations, impure language, and amazing blasphemies of a maniac now, as often heretofore, indicated the place sought after. In a stall built under a woodshed on the road was a naked man, defiled with filth, furiously tossing through the bars and about the cage portions of straw (the only furnishing of his prison) already trampled to chaff. The mass of filth within diffused wide abroad the most noisome stench. With strange curiosity and eager exclamations were gathered, at a safe distance, the children of the establishment, little boys and girls, receiving their first lessons in hardness of heart and vice; but the demoralizing influence was not confined to children."

(To be continued.)

MY EXPERIENCE WITH HYPERACIDITY.¹

BY G. LIEBMANN, M.D.

To say that the treatment of hyperacidity has been to me so far a source of unmitigated perplexity and puzzle and, therefore, unsatisfactory in the extreme, would be putting it mildly. In the very nature of things the prospect of improving, or even curing, this secretory disorder should be most attractive to the physician, from the fact that here at least he is face to face with a well-defined abnormal, chemical condition, which to change and remove simple antidotal remedies suggest themselves readily. Here an abnormally large amount of acid, and here the sufficient amount of alkalis. What could be simpler than this chemical formula? But, alas, practice does not always bear out such theoretical reasoning; and my successes in following it out were few and far between. While antineurotic treatment in some cases gave good results, and also a diet consisting of proteids only was borne remarkably well, other cases of hyperacidity, apparently not differing in their clinical features or chemical behavior from the first ones, and treated in the same way, proved refractory and yielded to drugs and foodstuffs ordinarily used and efficient in chronic follicular catarrh.

But these apparent discrepancies between diagnosis and treatment are about to be removed. Up to the present time it was the generally accepted opinion, that hyperchlorhydria (increased secretion of the normal amount of hydrochloric acid, free and combined), if we may exclude *ulcer* in a given case, is always the result of a *neurosis* of the secretory sphere and that an inflammatory (catarrhal) process under such conditions would be out of all question. For in catarrh, it was held, the glandular cells are partially obliterated, partly clouded, or partly shrivelled up (Ewald), and under such conditions the amount of hydrochloric acid present must be either diminished or lacking entirely. Only a few days ago I found Dr. Danber, assistant of Professor Leube, in an article on "Continuous Gas-

tric Mucous Secretion," puzzled about a case of his, manifestly a case of chronic catarrh combined with slight hyperacidity. "How the latter in such cases can be explained," the writer says, "must be left for the present time to the various diagnosticians"; and he thus leaves the explanation to others.

Yet in many cases of hyperacidity, symptoms and conditions indicating a neurotic state were lacking, while those pointing to catarrh were present. Much as the abnormally high percentage of hydrochloric acid indicated neurosis, yet the other symptoms were those of an organic lesion. It was cases like these that, with their conflicting and misleading symptoms, baffled a correct diagnosis or an intelligent therapy. There was but one way out of this difficulty and this was the demolition of the tenet, that hyperacidity (*ulcer* excluded) is always the result of a neurosis and the assumption of the possibility of a *sour catarrh*. My chemical formula and guide so far has been.

Hyperacidity = Neurosis;
and my therapeutic formula.

Hyperacidity = Nervines.

These formulas had to be abandoned.

It was at this very juncture that the timely researches of Boas, Epstein, Hayem, and especially Paul Cohnheim, together with their examinations of bits of mucous membrane obtained in lavage or excised during operations on the stomach of the living subject, threw much light upon this very point. The results of these examinations also helped to clear up the situation and explain away the apparent discrepancies. It was found that there actually exists, beside the ordinary chronic catarrh with its wholesale destruction of gland cells, another variety, a *gastritis acida* or *gastritis prolifera* based on different anatomical lesions. These lesions consist, according to Boas and Paul Cohnheim, in the proliferation (abundant production) of the cover cells and a waste of the main cells of the glands.

The researches of Paul Cohnheim show, furthermore, that the function of secreting hydrochloric acid (if not the digestive ferments as well) devolves upon the cover cells exclusively, and that in case of a proliferation of these the amount of hydrochloric acid secreted must be in excess. The waste of the main cells, on the other hand, would not interfere with this hypersecretion, while mucous degeneration of the foveal layer (and not the gland cells) constitutes the so-called *gastritis mucipara* (gastritis parenchymateuse muqueuse of Hayem). Moreover, round cell infiltration of the foveal layer accompanies these anatomical changes.

We learn from these far-reaching investigations, that there are two forms of catarrh: one, the ordinary follicular gastritis chronica, in which there is a decrease or lack of hydrochloric acid; and one, gastritis acida, acid catarrh, in which we meet with hyperacidity. Again, we learn that in case there are weighty reasons to assume the presence of the second condition the mere evidence of hyperacidity will not be incompatible with the diagnosis of catarrh. While, however, Hayem inclines to the opinion that all gastric diseases depend upon an anatomical lesion, others still believe that there are functional nervous disorders and that hyperacidity is a prominent representative of that type. My own opinion is in accord with this time-honored supposition. But the time has come when we must separate the two pathologically and clinically different conditions, the *neurotic* and the *catarrhal*

¹ Read before the Clinical Section of the Suffolk District Medical Society, May 19, 1897.

forms of hyperacidity. By doing this the diagnosis and treatment of this protean disorder will be vastly simplified; and already the recognition of this fact has borne me some good results.

As to the *prognosis* of hyperacidity I find upon reviewing my cases, that where the diagnosis of neurotic hyperchlorhydricity can be made, treatment was followed by better results (that is, immediate better results; whether these were lasting is a question I am not prepared as yet to answer in the affirmative) than in the catarrhal form. Prognosis, then, would be better in the neurotic than the catarrhal variety.

But how are we able to distinguish the two forms? Results in the treatment of such cases, and what is even more, the experience gained from "*juvantibus et noscentibus*," with sifting of objective and subjective symptoms, enabled me to come to the following conclusions, conclusions which I embodied in the following tables:

HYPERACIDITY.

NEUROTIC.	CATARRHAL.
LAVAGE, of little or no service.	Long continued, beneficial.
PEPSIN, of no service.	Of little value.
BISMUTH, allays burning pain.	Of no service.
NERVINES (assafoetida, bromides), massage, electricity, hydrotherapeutics, beneficial.	Negative result.
SYMPTOMATIC alkaline treatment, beneficial.	Beneficial.
NITROGENOUS diet (meat, eggs) well borne.	Gives distress, meat more so than eggs.
NEUROTIC form often part of other neuroses (hysteria, neurasthenia).	Catarrhal form not dependent upon neuroses.
APPETITE not decreased, but mostly increased.	Never increased, but often disturbed and lacking.
VOMITING absent.	Frequent.
TONGUE clear, moist, pale-red.	Coated with a thin fur, white and dry.
MUCUS in washwater, absent.	Present, mostly in large amounts.
SUBJECTIVE symptoms present, as burning sensation, sensation of cold (hyperaesthesia); a gnawing, empty sensation (bulimia).	Not much of a pain or burning sensation, but a feeling of fullness, pressure in epigastrium.
ERUCTIONS of odorless gases.	Of bad-smelling gases.

By way of illustration I add a few cases from my private practice.

CASE I. Case of hyperacidity with hypersecretion. J. E. I., twenty-six years old. Fair, ruddy complexion, blond. Thin muscles and gracile bones. Had always a weak stomach. Since a couple of years a burning at the pit of stomach, with an occasional regurgitation of food; the burning sensation is continuous and independent of food or drink. Appetite tickle. No vomiting. Drinking a glass of water produces easily a splashing sound, the limit of which is marked above the umbilicus.

February 18, 1896. Stomach contents examined after a test breakfast, with the following result:

Total acidity	120
Hydrochloric acid	3.6
Biuret test	+
Erythro-dextrin	+
Rennet	-

February 20th. Tube introduced into fasting stomach. Escape of 150 c. c. of a yellow-greenish fluid. Afterwards lavage. Large amount of food remnants from preceding supper, taken some twelve hours before. No mucus. Tongue clean, pale-red. No eructation of gas, but some regurgitation of food.

February 26th. Breakfast, consisting of three raw eggs, white bread and milk, followed by no burning sensation. Only slight regurgitation of food. No

other signs of catarrh — a disagreeable pasty or salty taste in mouth. No dryness of lips; no coated tongue. Lavage. Bismuth. Stomach fairly empty.

March 3d. Burning pain has left patient. Still some little regurgitation of food, especially after eating soup. Stopped latter. External galvanism, bismuth, and an occasional pinch of bicarbonate. Ample nitrogenous food. Secretion of stomach about normal in quantity. Lavage.

March 10th. Feeling well. Some motor insufficiency still in evidence (atony). Hydrochloric acid .22.

November, 1896. Entirely relieved. This case is a fair sample of neurotic hyperacidity. The only symptom that could be claimed for the assumption of a catarrhal state (the slight regurgitation of food) is easily explained by the motor insufficiency. Ulcer could be excluded by the fact of the case yielding so readily to treatment and the independence of pain from taking nourishment. Whether the presence of a large amount of a yellow-greenish fluid found in the fasting stomach was the result of a real neurotic hypersecretion, or due to the retention of the normal secretions in the stomach as the result of a pyloric spasm, the latter caused in its turn by the abundance of hydrochloric acid, I am not prepared to decide. Lavage in this case seems to have been of good service, as it removed the hypersecreted fluid.

CASE II. October 7, 1895. Acid catarrh. C. S., age fifty-two. Was delicate in his tender childhood. From his sixth year on, never sick up to some five years ago, when he began to have symptoms of indigestion — a bad taste in mouth on getting out of bed, a fulness and pressure in epigastrium, slight nausea, constipation. All these symptoms still present, but constipation not so marked at present. Appetite was always good. Sleep at times disturbed. Flatulency. No eructations. Tongue thickly coated with white fur.

October 9th. Total acidity 100; hydrochloric acid .40106.

October 11th. Lavage. No remnants of food in washwater. Some mucus of greenish tint. Diet mostly nitrogenous. Bicarbonate in one-half-drachm doses, twice daily.

October 18th. Had some very bad days since last visit, but much more comfortable to-day. Tongue still covered thickly. Diet same. To clean tongue, a pill of two and a half grains of blue mass at night.

October 22d. Tongue still coated as heavily as before. Urine contains no sugar, no albumin. Splashing sound audible with stomach fasting. Subjective feeling much better; feeling of pressure gone for four days. Total acidity, 80; hydrochloric acid .29168, lactic acid, —; dextrin, +; biuret test, +; sugar indistinct. Apparently digestion of starch suspended or nil.

November 6th. No oppression in epigastrium; no flatulence. Appetite increased. Tongue still heavily coated, white, taste in mouth more natural. Lavage continued once a week. Occasional dose of blue mass. Nitrogenous food.

November 21st. Subjective symptoms still satisfactory, but tongue's appearance unchanged.

This then is clearly one of those cases of hyperacidity which, without assuming a catarrhal form, could hardly be accounted for. Even if there were some neurotic elements in the history of the case (tender,

delicate constitution, some nervous excitability) yet the decided catarrhal features, as mucus in the wash-water, the covered tongue, the perverted taste in mouth, militated against the assumption of a neurosis. Still there was the surplus of hydrochloric acid, that in its turn demolished the diagnosis of catarrh. The only solution of this puzzling problem is the assumption of a hyperacidity depending, not upon a neurosis, but on acid catarrh. This interpretation would, of course, place the above case under the head of the catarrhal variety of hyperacidity.

CASE III. Nervous hyperacidity. Miss M. T., fifty-two years old, felt a quivering and trembling in the epigastrium when a child. Menstruated the first time in her thirteenth year. Digestive troubles began eighteen years ago: pressure in epigastrium with little burning; abdomen distended; never vomiting; taste in mouth normal; tongue clean, moist, of normal color; lips moist; appetite fair; sleep disturbed; general weakness; works hard mentally (private teacher).

June 18, 1896. Total acidity 90; free hydrochloric acid .33750; biuret test positive.

June 19th. Lavage. No food remains.

June 20th. Lavage. No improvement.

June 21st, 22d, 23d. Same result.

As lavage was each and every time followed by nervous excitement (trembling, increased weakness) it was discontinued. Ordained bicarbonate of soda. Rest, cold ablutions, indirect galvanization.

July 2d. Some improvement, but had to stop the bicarbonate as it gave distress.

July 15th. Feeling much relieved. Sleep more quiet; but yet some oppression and heat in stomach region. Ordained ample mixed food. Galvanization continued. No more medication.

July 30th. Has not taken any drug since July 15th—only cold ablutions or a casual Prinsitz on epigastrium, ample food, continued daily application of faradic current (kathode in epigastrium). Patient feels herself strong. Appetite keen; sleep almost undisturbed; increase of bodily weight.

September 1st. In very good condition and fine spirits. Hydrochloric acid 2.2 per thousand. Still takes electricity and sponge baths; stomach bears almost all foodstuffs; weight still increased.

In this case lavage proved positively harmful; alkalies gave no relief; while roborant and electric treatment was of decided benefit.

A SIGN OF CARDIAC FAILURE.¹

BY HENRY JACKSON, M.D.

I wish to bring to your notice this evening a few charts illustrating one of the signs of cardiac failure which is of great import though it meets but little notice in the articles upon cardiac failure, namely, a discrepancy between the rate of the arterial pulse and the rate of the heart-beats. I have observed in many instances that in cases of extreme cardiac weakness the pulse was very slow, intermittent and irregular, while the heart was rapid, and I refer not to cases in which it is extremely difficult to count the pulse, as is always the case when the pulse is irregular, especially

when the rhythm of the pulse is irregular, but to cases in which the most accurate taking of the pulse by trained individuals does not show a rapid pulse-rate, yet examination of the heart shows that its action is extremely rapid.

The charts which I have to show to-night are charts taken from dilatation of the heart from chronic disease which may be called broadly disease of the myocardium. I have also seen the same phenomenon in acute dilatation of the heart and in acute degeneration of the heart in infectious diseases, namely, several times in diphtheria and once in typhoid fever. The typhoid fever case was one of a man who appeared very sick, and yet the chart did not indicate a rapid pulse. Examination of the heart with a view of determining if there were any acute process in the heart showed that the heart was rapid. With convalescence that phenomenon disappeared, and it has disappeared also in the acute heart failure following diphtheria in those cases that I have observed.

The first case which I saw was when I was house-officer at the Massachusetts General Hospital. A man came in with extremely irregular heart, a very nervous man in generally run-down condition. No organic lesion was discoverable, and it was supposed to be a functional heart trouble, due perhaps to excessive smoking, as he said he smoked all the time except when eating and sleeping. He went out after a few days and returned very sick, with an apex beat of 140 and a pulse of 70. There was then discoverable a slight dilatation of the heart; and in the course of two weeks there was a very rapid increase in the size of the heart, and with that increase there was the development of a diastolic, regurgitant murmur in the aortic region, which was supposed at the time to be due to an acute ulcerative process in the valves. Under digitalis the heart gradually became slower, and the man ended his stay in the hospital by becoming insane and was transferred to Danvers.

The other cases I will briefly detail. A man of forty; great alcoholic excess, no rheumatism. Had previously had pneumonia. Dyspnea. Edema several weeks. Heart increased two inches to the right of the sternum and one inch to the left of the nipple line. No murmur. Orthopnea. Under digitalis he got gradually better, but suddenly died.

Another man, forty-five; alcoholic excess. Six months' shortness of breath, edema; pulse irregular, intermittent. Heart dilated, systolic murmur at the apex. Gradual improvement under digitalis. Up and about the wards in a month; and when discharged was much relieved, the pulse and the apex-beat corresponding in rate. Diagnosis myocarditis, or I should rather say, some disease of the myocardium.

A man of forty-five. No alcohol. No rheumatism. Had been a laborer who had done excessively hard work. Arteries sclerotic. Came in for chronic bronchitis. Heart somewhat dilated. At first great improvement. Put in convalescent ward; and we were expecting to discharge the man soon, when he became much more sick. There supervened attacks of pulmonary infarction; little areas of fine râles scattered through the lung, with bloody, thick expectoration and acute rapid dilatation of the heart; excessive edema; death after several weeks in the hospital. At one time the pulse and the apex came very near together.

Man of fifty, brought to the hospital practically

¹ Read at the Clinical Section of the Suffolk District Medical Society, May 19, 1897.

moribund: extreme cyanosis, cold sweat, great dilatation, systolic murmur. Died in thirty-six hours. Apex-beat 170, pulse 50, and the respirations 60 to 70. He was practically dying, and there was no possibility of completing the diagnosis as to the cause of the pathological condition.

Man of forty; alcoholic excess, dyspnea and cough for several months; heart dilated; edema; systolic murmur at the apex; arteries sclerotic. Gradual improvement. Heart 120 on entrance, pulse 70, and they gradually came down until they met at 80.

The last case was a woman, sixty-five; short of breath several years. When I saw her she was in bed, cyanotic, heart dilated, systolic murmur at the apex. Gradual improvement. On December 18th, probable pulmonary infarction; December 20th, she died. On the 18th the respirations suddenly rose to 40, and continued so to the time of her death. At one time the heart and pulse came quite close together.

So far as I am acquainted with the literature, the only one who has drawn attention to this is Dr. Whittier in an article he wrote on cardiac failure, and in that he simply shows a chart quite similar to these I am passing about; but unfortunately he made no reference to the phenomenon, merely wrote under the chart, "Case illustrative of cardiac failure in discrepancy between the pulse-rate and the heart-beats."

DIGESTION LEUCOCYTOSIS AS AN AID IN DIAGNOSIS OF CANCER OF THE STOMACH.¹

BY J. A. CAPP'S, M.D.,

Medical Intern at the Massachusetts General Hospital.

It has long been known that in most healthy individuals after a proteid meal there is an increase in the number of leucocytes in the blood, which comes on gradually and reaches its maximum in three or four hours. This normal variation may be further exaggerated by starving the subject for twelve or more hours previous to the meal; and under these circumstances the white count goes up on an average about 33 per cent. To this increase the term "digestion leucocytosis" has been applied.

The first practical use of the facts was suggested in 1890 by Müller,² who found digestion leucocytosis absent in five cases of gastric cancer, and considered it therefore of possible value as a diagnostic test.

No serious investigation was undertaken, however, until 1895, when Schneyer³ reported the invariable absence of digestion leucocytosis in 18 cases of cancer of the stomach, including both early and late stages, although in five of the number free hydrochloric acid was present. He found a marked digestion leucocytosis in seven of eight cases of gastric ulcer, the exception being a fatal case.

Hartung's⁴ results were equally positive, all of 10 cases of advanced cancer of the stomach showing an absence of digestion leucocytosis, whereas a marked increase in the number of leucocytes occurred in cases of malignant disease in other organs.

The accompanying table shows 30 cases from the Massachusetts General Hospital in the wards of Drs. F. C. Shattuck, Cutler and Vickery, by whose kind

permission this report is made. The series fairly represents that class of cases with gastric symptoms in which cancer of the stomach must be considered in the differential diagnosis.

In each patient the capacity of the stomach was estimated, and an analysis made of the gastric juice expressed through a tube about two hours after an Ewald test breakfast with the addition of a little finely minced meat.

The test for digestion leucocytosis was carried out in the following manner: After twelve hours' abstinence from food, the patient was given a glass of milk, two eggs (raw or cooked), and a sandwich of minced meat. Immediately before or after eating, the leucocytes were counted, and a second time between three and four hours after the meal. Care was taken to count the equivalent of the total ruled area with the Thoma-Zeiss white counter at least ten times and in two or three different drops.⁵ By this precaution the error of counting is reduced as much as possible.

An increase of less than 2,000 white corpuscles in a cubic millimetre of blood was not considered sufficient for digestion leucocytosis, since allowance must be made for mechanical errors. If an increase of 1,000 to 2,000 took place, the result was doubtful and the test repeated.

The higher the white count is, the greater is the absolute error in counting; hence, where the leucocytosis is very large, for example, 30,000 or above, it becomes very difficult to appreciate a variation of 3,000 or 4,000 from digestion, and the test loses most of its value.

In the series there are 17 cases of undoubted cancer of the stomach, as demonstrated by the subsequent course of the disease or by autopsy. Comparing some of the most constant signs of gastric cancer, that is, tumor, presence of lactic acid, and absence of free hydrochloric acid, with the digestion leucocytosis test, we see that in these 17 cases tumor was absent in four instances, hydrochloric acid present four times and lactic acid about four times, while digestion leucocytosis occurred but twice, for example, the digestion leucocytosis test was the most reliable of all.

Digestion leucocytosis was present in the three cases of ulcer and two of simple dilatation of the stomach, as well as in two cases of malignant growths of the liver and adrenal glands, where the stomach was not involved. It was absent, however, in three or five cases of chronic gastric catarrh.

Case 30 cannot be definitely classified, and for that reason a brief history is given:

A man of forty years entered the hospital March 4, 1896. No history of cancer in the family. Habits and health previously good. His present illness began six months before entrance, the chief symptoms being gastric distress after meals, anorexia, daily vomiting of small quantities of food, flatulence and considerable loss of flesh and strength. He had never noticed any "coffee grounds" in the vomitus, but the stools were often dark-colored without being tarry. He was often troubled with acid eructations and sharp pain in the epigastrium. Bowels always regular. When examined he was rather pale, but not emaciated nor cachectic. There was tenderness to pressure over the epigastrium; no tumor felt. Blood analysis showed

30	40	Mar. 12, 1896	Doubtful (probable ulcer of stomach).	6 mos.	5 pints.	Absent.	Present.	Absent.	12,270	14,300	2,030 +	Present.	Dec. 7, 1896, died of hemorrhage from stomach. No autopsy.

For report of Cases 2, 13 and 14, by Dr. Vickers, see Boston Medical and Surgical Journal.
For report of Case 19, by Dr. Cutler, see Boston Medical and Surgical Journal.

5,300,000 red and 10,000 white corpuscles, with 85 per cent. of hemoglobin. The stomach contents after a test breakfast contained free hydrochloric acid, no lactic acid and no blood. Total acidity 0.54 per cent. Capacity five pints. Digestion leucocytosis was present, but not marked.

The diagnosis at that time was "hyperacidity." Eight days later he was discharged, having been much benefited by lavage, frequent feeding, and especially by large doses of sodium bicarbonate. For the further history of the case the writer is indebted to Dr. G. Liebmann, of Boston, who had charge of it.

On April 7th the vomiting had ceased, but the patient was losing flesh. A distinct resistance was felt in the region of the pylorus.

November 12th. He had been suffering for six weeks from severe epigastric pain without much falling off in weight. Near the pylorus was a smooth, hard tumor, tender to pressure.

November 26th. Some improvement had taken place from daily washing. After a test breakfast the total acidity of the gastric contents were 0.8, hydrochloric acid 0.27 per cent., and lactic acid present in small amount.

December 7th. He died after several very profuse hemorrhages. Unfortunately no autopsy was made.

Probably the case was one of ulcer at the pylorus; and with this diagnosis the chemical analyses and presence of digestion leucocytosis perfectly accord, but the appearance a few weeks before death of a tumor which had previously not been present makes it impossible to rule out cancer. This case is therefore left out in all the conclusions hereafter to be drawn.

Examining the remaining group of 12 cases of non-malignant disease of the stomach, it is seen that in three tumor was present, in two hydrochloric acid was absent, in five lactic acid was present, and in three digestion leucocytosis was absent.

To summarize the 29 cases and compare the relative value of the various tests in the diagnosis of gastric cancer, we find that tumor was misleading in seven instances, hydrochloric acid in six, lactic acid in nine, and digestion leucocytosis in five.

Since hydrochloric acid is such an important factor in digestion, it might be supposed that digestion leucocytosis would depend upon its presence; but this is not always true, as illustrated by cases in which digestion leucocytosis is marked and hydrochloric acid absent, and, on the other hand, by cases in which hydrochloric acid is present and digestion leucocytosis absent. At autopsy the location and extent of the cancer in no way explained the occasional absence of hydrochloric acid or digestion leucocytosis.

As to the practicability of the digestion leucocytosis test, objection may be raised on the ground of danger to the patient from the proteid meal, especially in ulcer of the stomach; and of difficulty in the technique. In regard to the danger, the proteid meal is not much more irritating than the ordinary test breakfast; and, on the other hand, does not involve the risk of the tube. When there is fresh bleeding both measures are, of course, contraindicated. The difficulty in carrying out the test is that much more training and time is required than in the test for hydrochloric acid.

From this limited number of cases the following conclusions may be drawn:

(1) Digestion leucocytosis is absent in most cases

of cancer of the stomach, but not invariably so, as the results of Müller, Schneyer and Hartung would indicate.

(2) Digestion leucocytosis is present in ulcer and simple dilatation of the stomach.

(3) In chronic gastric catarrh digestion leucocytosis is frequently absent.

(4) The presence of digestion leucocytosis does not necessarily depend upon the presence of free hydrochloric acid.

(5) The presence of digestion leucocytosis is more against cancer of the stomach than its absence is in favor of that diagnosis.

(6) In spite of its limitations the digestion leucocytosis test seems of equal value with the hydrochloric-acid test in the diagnosis of cancer of the stomach.

Clinical Department.

A CASE FOR DIAGNOSIS.¹

BY C. G. CUMSTON, M.D.

THE interest of this case I desire to report is marred because the microscopical preparation that I had to show has faded, and nothing can be seen. I thought it rather apropos to report it to-night on account of the present epidemic of cerebro-spinal meningitis. I will state briefly the case, and leave the diagnosis for you to make:

A lady about thirty-four I saw two years ago with pus-tubes. At that time she had tubes on each side about the size of lemons, and simple treatment with mercurial ointment was sufficient to cause them to break down and discharge through the uterus. From that time to the present illness there have been no symptoms in the genital organs. The husband had syphilis ten years before he was married, was treated by a specialist, and had seen nothing of the disease for five or six years before he was married. He had had several gonorrheas, which had left him with a gleet; and after having treated the manifestations in the tubes of his wife I examined with some difficulty a drop of mucus taken from the meatus in the morning and found one or two gonococci. Since then I have treated him surgically, and his gleet has stopped.

On the 10th of this month I saw the patient in question. She had last summer what might be called a slight sunstroke, was in bed four or five days. She was at Mt. Desert, had been rowing without her hat, and she had certain symptoms which led me to suppose that there was a slight overheating of the head. This winter she was down town when the explosion occurred, and the windows of her carriage were broken by the shock near the old Public Library. This added to her already excited nervous condition. On the 10th of this month I was sent for. I had seen the patient the day before, and she was seemingly very well. I found her in the afternoon with a temperature of 39.4°, chills, with the bright-red coloring of the face which you find in pneumonia, and, in fact, every appearance of pneumonia—pulse 130, hyperesthesia all over the skin of the trunk and arms, the legs apparently not being involved in this hyperesthetic condition and severe cephalalgia was complained of. At my even-

¹ Read before the Clinical Section of the Suffolk District Medical Society, April 21, 1897.

ing visit, about five hours later, the temperature had dropped to 37.8° and the pulse to 102, and she was feeling better. I had some of her sputum collected, but what the nurse gave me had not the rusty color of pneumonia. The next morning her temperature was 37.5°, the pulse had dropped to 86, and the respirations, which were 32 the day before, had dropped to 18. The hyperesthesia still continued, and the patient still complained of considerable headache in the frontal region. In the afternoon the temperature was 37.9°, the pulse had increased in frequency, the headache was more severe, there was pain in the muscles of the neck, and the patient then began to present the characteristic symptoms of a cerebro-spinal meningitis. In the lung, in consultation with Dr. Sumner, a focus of pneumonia in the left lower lobe about what might be covered by the end of the stethoscope was discov-

ered, and that was the only lesion in the lung we could find. To be brief, the case went on in this way: The headache increased the second night so that it was intolerable; she protruded her tongue towards the left; pressure over the eyeballs was painful; and stiffness of the neck was complete. Blood examination revealed a slight leucocytosis. On the fourth day a labial herpes appeared and on the seventh the same eruption was present on the left labium majorem. The treatment I instituted was pomade of mercurial and simple ointments, equal parts, and to every thirty grammes of this five grammes of iodol were added. Chloral hydrate, one gramme, as often as required. The patient has begun to improve since she received this treatment, and is now convalescing. The pulse is normal, respirations have dropped, temperature normal. The headache gradually subsided and by the tenth day only soreness of the neck was complained of.

On the second day, when I examined the sputum, I found what I thought were gonococci; and I came to the conclusion that my glasses were not clean, and made more preparations and found the same organism. In looking over the *Boston Medical and Surgical Journal* of this week I found an editorial on the lanceolatus in the pus from cerebro-spinal meningitis. In examining carefully I could find these cocci were distinctly limited by a membrane, so that I came to the conclusion I was dealing with the pneumococcus lanceolatus.

Was I dealing with a case of cerebral syphilis, cerebro-spinal meningitis with a primary focus of pneumonia in the lung, or infection due to the former lesion in the tubes and ovaries? I cannot say; but my impression is that the case was one of infection of the envelopes of the brain and spinal cord, having for a starting-point the small focus of pneumonia in the base of the left lung produced by the pneumococcus lanceolatus from which the organism invaded the brain and cord, giving rise clinically to a cerebro-spinal meningitis.

The chart is shown herewith. It was taken by the nurse, and verified by me at each visit.

I would add that during the first week the patient received by inunction 75 grammes of iodol and 22 grammes of metallic mercury. No untoward effect was produced.

N. B. October 15, 1897. The patient has improved wonderfully during the summer. The tongue continued to be protruded to the left until September, but now is normal. Patient has gained four kilogrammes in weight and her head is perfectly clear.

A CASE OF DIPHTHERIA OF THE VULVA.¹

BY W. P. COUES, M.D.

CORA L., age eight months, was admitted to St. Mary's Infant Asylum, April 6, 1897. A complete past history was not obtainable. The father lived in Boston, and had put the child out boarding before she entered St. Mary's.

On April 7th my attention was called to the child by the nurse, who informed me that the child had passed no water that day, and that there seemed to be something wrong with the vulva.

Examination showed a feeble, ill-nourished child of eight months. The labia minora were greatly swollen, of a deep-red color, with two patches of grayish-yellow membrane, the size of one's little finger nail, on either side. Temperature 99.5°, pulse 128. A hot bath was ordered, and a sulpho-naphthol poultice to the vulva, the child to be catheterized, if necessary.

On April 8th the general condition was about the same, the child had urinated without catheterization. The labia were less red and swollen; the membrane was the same.

The aspect of the case was clinically so like diphtheria that I decided to take a culture; and on April 10th the card came back positive.

The membrane by this time had spread somewhat over the labia minora, and two small spots appeared on either labia majora. The general condition of the child was worse. She was weak and fretful. Temperature 100.8°, pulse 130. An injection of five cubic centimetres of antitoxin was given in the left axillary line.

¹ Read before the Clinical Section of the Suffolk District Medical Society, May 19, 1897.

The child was then sent to the Boston City Hospital, South Department. She made a slow recovery, being discharged on May 7th, about one month from the time of her entrance.

When the child left St. Mary's the clinical examination of the throat was negative, but unfortunately no bacteriological examination could be made at that time. I am informed that after her admission to the City Hospital positive culture was obtained from the throat. There was at no time clinical diphtheria in the throat. I am inclined to think that the infection was carried there from the vulva by the child's fingers, but it is, of course, impossible to say positively which place was the primary seat of infection.

Medical Progress.

REPORT ON PROGRESS IN THORACIC DISEASES.

BY GEORGE G. SEARS, M.D., BOSTON.

THE DIAPHRAGM PHENOMENON OF LITTEN IN PULMONARY TUBERCULOSIS.¹

RUMPF has made a careful study of the diaphragm phenomenon in 70 cases of phthisis. He confirms Litten's statement that it is normally visible between the seventh and ninth ribs, and has an extent of six or seven centimetres; but he points out that even in normal chests it may be less extensive because the patient either does not know how to use the diaphragm in respiration or wilfully refuses to. It may also be less marked on one side than the other for similar reasons. As a result of his investigations, which are reported in considerable detail, he says that in tuberculosis of the lungs it has no real diagnostic value. All that one can say is that, as a rule, it is diminished on the affected side, yet a normal movement by no means rules out tuberculosis, and an abnormal one may be produced by other diseases or by accident. Neither can any positive conclusions be drawn as to the extent of the process, further than that, if the visible movement is present in its normal extent, no very considerable portion of the lungs has been invaded. It may, however, have a decided value in the diagnosis of subphrenic abscess or diaphragmatic hernia as well as in determining the effect of treatment, since in the author's experience an increase in the extent of the motion was always accompanied by an increase in the chest capacity as determined by the spirometer. It may also be sometimes useful in detecting malingerers. In conclusion, he says that since the phenomenon does not always correspond with the severity of the disease, and that diseases of other organs as well as other factors, such as sex, obesity, habit, intelligence and the inclinations of the patient influence its development, it is hardly to be expected that it will be widely used in practice.

MERCURY IN TUBERCULOSIS.²

At a meeting of the Paris Academy of Medicine, Dubois presented a communication in the form of a preliminary note on the use of mercury in the treatment of tuberculosis, in which he said that, relying on the activity of the drug as an antiseptic as well as on

its power to prevent tissue-waste he had prescribed it for the past five years, and that the results had surpassed his expectations. It was still too soon to speak of cures, but he had produced such improvement that patients had been able to take up their former occupations and mode of life with scarcely a thought of their pulmonary trouble. The early results were so striking that he had at first thought that he was dealing with cases of syphilis; but the frequent repetition of his success compelled him to abandon this idea and rather led him to think that many of the alleged cases of pulmonary syphilis cured by mercury were, in reality, tubercular. He employed a one to one thousand solution of bichloride of mercury made without alcohol. Half a cubic centimetre of this solution was injected in the subspinal or subclavicular region every second day, the dose being increased after a fortnight to one centimetre. These injections caused quite sharp pain, but not more than the patient could endure. If they had to be omitted for several days for any cause three or four grains of blue ointment were rubbed into the axillary region instead. No unpleasant accidents happened, and improvement was noticed in all stages of the disease, most marked, however, in the early cases. Laborde, to whom this note was submitted for investigation and criticism, gives in his report the histories of several cases, and says that the results were such as to encourage further trial of this method of treatment.

THE SIGNIFICANCE OF A PRESYSTOLIC MURMUR AT THE APEX OF THE HEART.³

Kasem-Beck says that a presystolic murmur at the apex of the heart is ordinarily a characteristic sign of mitral stenosis, but recently a number of cases have been reported where in spite of its presence the autopsy showed no narrowing of that orifice. In many of these cases aortic insufficiency and mitral stenosis were diagnosed during life, but section showed the presence of the former only. In another series of cases the presystolic and diastolic murmurs which were heard were found to result from an adhesive pericarditis and not from an aortic and mitral lesion. Phear has described a case where the only lesion was an enlarged left ventricle, and lately Picot has described a presystolic murmur in certain hysterical individuals which he ascribes to a contraction of the papillary muscles.

Kasem-Beck adds a case in which none of these causes were present. The patient, a man sixty-three years old, complained of severe dyspnea, and of pain in the chest extending into both arms. A venous pulse was present in the neck, the heart was greatly enlarged and the impulse so strong that there was a marked heaving of the intercostal spaces. The arteries were sclerotic. Auscultation revealed a loud presystolic murmur at the apex, and a muffled first sound. The first tricuspid sound was also muffled; the second was normal. The second pulmonic sound was accentuated. Autopsy showed no narrowing of the mitral orifice but a relative insufficiency of both that and the tricuspid. Near the apex there was an aneurysmal dilatation of the left ventricle as large as a medium-sized apple. It is probable that the presystolic murmur resulted from a deviation of the blood-current in the cavity of the left ventricle due to the aneurysmal dilatation.

SINUS-PLEURITIS.⁴

Koll describes a form of localized pleural inflammation under the name of "sinus-pleuritis," which appeared almost in the form of an epidemic, thirty cases being observed in the hospital at Würzburg between the fall of 1894 and the summer of 1895. In most of the cases the disease began suddenly, like an acute infection, with a slight rise of temperature and some constitutional disturbance, while in a few instances there was an initial chill. The subjective symptoms were such as to suggest the presence of an acute or chronic gastric affection, and consisted of more or less circumscribed pain in the region of the stomach or at the point of the ensiform cartilage, which was often increased by food or pressure — nausea and vomiting were fairly constant symptoms, and forced inspiration was often very painful. Palpitation of the heart was also common, the pulse rising in a few instances to 140. The only constant physical sign was a soft friction sound almost exclusively confined to the pleural sinus in the neighborhood of the heart and extending along the lower lateral border of the lung, but practically never overstepping it. It was sometimes heard, however, along the border of the right lung. Ordinarily the most severe symptoms soon passed, but a slight evening rise of temperature very frequently persisted for weeks, while the physical signs remained almost indefinitely. Relapses were frequent. Koll believes that this form of pleurisy is comparatively common, but is overlooked partly because the symptoms point rather to a gastric disturbance or some affection of the heart or pericardium, and partly because the signs are found in a portion of the chest which is rarely very carefully examined.

THE INFLUENCE OF MITRAL LESION ON THE EXISTENCE OF PULMONARY TUBERCULOSIS.⁵

From the statistics which Graham has been able to collect on this subject, embracing a very considerable number of cases, as well as from the observations of eminent physicians, he draws the following conclusions:

(1) That primary mitral disease and pulmonary tuberculosis rarely exist in the same individual. It would appear that in uncomplicated cases, namely, those in which the other valves are healthy, mitral stenosis occurs more frequently in combination with tuberculosis, whereas when the other valves are affected insufficiency is the more frequent condition.

(2) That pulmonary tuberculosis is a very frequent sequel to pulmonary stenosis.

(3) The presence of mitral disease acts as a preventive to tuberculosis, especially when the vital powers are at or near their normal standard, and the prophylactic agency is shown in those who have an hereditary tendency to the disease and whose surroundings are of a decidedly unhealthy character.

(4) In the small number of cases in which tuberculosis follows a mitral lesion during middle life, its evolution is very much delayed. When, on the other hand, from age or bad habits, the vital powers are on the decline, the process is often as rapid as in ordinary cases.

He attributes this immunity to the increased amount of blood in the lungs, the greater expansion of the apices and the increase of the involuntary muscular

fibres of the bronchial tubes and alveoli. In the opposite condition, where there is a diminished amount of blood in the pulmonary circulation statistics show a greater tendency to tuberculosis, for example, in cases of pulmonary stenosis.

From the practical side, as a therapeutic measure, it would be out of the question to induce passive hyperemia of the lungs, even if we knew how it might be brought about, but an active hyperemia would no doubt have a similar effect, and to this unquestionably the improvement produced by high altitudes and appropriate pulmonary gymnastics must in part be ascribed.

REMARKS ON WOUNDS OF THE HEART.⁶

The tolerance of the heart to penetrating wounds is well shown by two cases reported by Turner.

In the first a sewing needle had been driven into the heart of a child two years old. The whole needle had disappeared into the chest, but its head could be felt underneath the skin tapping against the finger with each beat of the heart. It was cut down upon and extracted without evident harm resulting.

In the second case, the patient, a young man, was admitted to the hospital in a state of extreme collapse, bleeding freely from a wound in the left side of the chest in the region of the heart, which had probably been made by a large knife. The cartilage of the fifth rib was penetrated longitudinally by a slit one and three-quarter inches long. Bright arterial blood in considerable quantity was issuing in jets synchronously with the cardiac contractions, and air also passed with a loud hissing sound with each respiration. The heart sounds were muffled and the pulse at the wrist was almost imperceptible. The whole left side of the chest was flat on percussion. A week later the patient's condition was still very critical. A sero-sanguinolent fluid was escaping in large quantities from the wound and a left pneumothorax had developed. A month later the fifth rib was resected posteriorly and thorough drainage of the pleural cavity secured. The immediate effect of the operation was satisfactory; and four months and a half later the patient was able to move about in a wheel-chair. One morning while sitting up to have his wound dressed, he suddenly threw back his head, had a convulsion, and died after a few hours. An autopsy showed that the immediate cause of death was cerebral hemorrhage. The pleura was adherent to the pericardium, the interior of which as well as the surface of the heart was granular. Some fluid was found in the pericardial sac. There was a cicatrix in the pericardium corresponding in position to the external wound, and immediately subjacent to it was discovered a cicatrix in the anterior surface of the heart itself. This was three-quarters of an inch in extent, horizontally placed, and was situated over the intra-ventricular septum about one and one-half inches from the apex. The wound was found to have penetrated to a depth of five-eighths of an inch into the muscular substance. The left coronary artery and vein had been cut across. Apparently the wound of the heart had only a remote influence in determining the fatal issue. It appears almost certain that after the infliction of the wound the pericardium must have been filled with blood from the division of the coronary vessels, and yet the heart's action was not thereby brought to a standstill.

A CASE OF POSITIVE CENTRIFUGAL VENOUS PULSE WITHOUT TRICUSPID INSUFFICIENCY.⁷

Futran reports the following case: The patient, a painter, forty-nine years old, had never been seriously ill up to four years ago, when he began to lose flesh and complain of cough, dyspnea and palpitation. For a year he had noticed occasional edema of the feet. The lips were cyanotic, the sclera somewhat icteric, and the feet and ankles edematous. In the neck a marked pulsation was noticed in the venous trunks as well as in the arteries. In the former the pulsation was not influenced by respiration and when compressed by the finger the veins continued to pulsate only on the central side. With the patient in a horizontal position a similar pulsation was visible in the cephalic veins and occasionally also in the basilic. It was only rarely seen in the median. The peripheral arteries were thickened and tortuous. A capillary pulse was not present. The area of cardiac dullness extended upwards to the upper border of the third rib, on the right a finger's breadth to the right of the sternum, and on the left a finger's breadth and a half outside the mamillary line. The apex beat was in the fifth space a finger's breadth outside the line of the left nipple. On auscultation a loud systolic murmur was heard in the mitral area with normal second sound. The first pulmonic sound was impure, the second accentuated. Except an accentuation of the aortic second and the tricuspid first, the sounds in the tricuspid and aortic areas were normal. A blowing systolic murmur was heard over the median vein of the neck with a *bruit du diable* over the jugulars. The double arterial sound of Traube and Duroziez's double murmur were both absent. The liver was considerably enlarged but did not pulsate.

In discussing the differential diagnosis Futran says that the fact that no change was noticed whether the patient breathed or not rules out respiratory alterations in the intrathoracic pressure as a possible cause, while the persistence of the pulsation on the central side of the point of compression and its cessation on the peripheral shows conclusively that it was primary and not produced by the movement of neighboring arteries, nor could it have been caused by a compression of the superior vena cava by the pulsating aorta. The so-called negative venous pulse could also be ruled out since the pulsation here was systolic in time. The possibility of the wave being transmitted through the capillaries could also be readily excluded, leaving a true centrifugal venous pulse alone to be considered, which, in the absence of a murmur in the tricuspid area, and the presence of an accentuated pulmonic second sound, could not have been due to tricuspid insufficiency. The only possible explanation would be found in the presence of an opening between the two auricles, perhaps through the persistence of the foramen ovale, by means of which the blood which was under increased pressure in the left auricle, owing to the mitral insufficiency, was forced backward into the veins. Reisch and Rosenstein have each reported a similar case, where the diagnosis was proved by an autopsy. In the present instance, the patient improved under treatment.

PROFESSOR VON ESMARCH has recently celebrated his silver wedding with his second wife.

⁷ Berl. klin. Woch., February 8, 1897.

Reports of Societies.

CLINICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

E. W. TAYLOR, M.D., SECRETARY.

REGULAR Meeting, April 21, 1897, the President, DR. W. F. WHITNEY, in the chair.

DR. HENRY JACKSON read a paper on

A SIGN OF CARDIAC FAILURE.

DR. BARNEY: In the few cases in which digitalis was given in large doses at the Massachusetts General Hospital, it was noted when the heart-rate and the amount of urine were taken together in the chart, and digitalis given several days, the pulse-rate and heart-rate came together; and if digitalis were kept up, the pulse-rate and heart-rate would generally gain. It may be an indication that digitalis is needed or a toxic effect of digitalis.

DR. TOWNSEND: I remember very distinctly the case Dr. Jackson speaks of, and I have observed the phenomenon in other cases. I think it is something we must be on the lookout for where the pulse at the wrist is slower than we would expect from the general condition of the patient.

DR. JACKSON: My impression has been that it was ineffectual contractions of the heart which were too weak to transmit the blood over the system. I may be mistaken, but that is my feeling. In a good many of these cases you will see the apex was twice as rapid as the pulse, indicating that only half of the beats were transmitted to the wrist.

Recent Literature.

A Contribution to the History of Leprosy in Australia.

By J. ASHBURTON THOMPSON, M.D., D.P.H., Pp. 238. London: Macmillan & Co. 1897.

This work has been prepared and published under the auspices of the National Leprosy Fund of Great Britain. The author has collected data showing that the original population was free from the disease up to a very recent period, since 1892 in fact. Leprosy appeared as early as 1855, introduced by the Chinese, no doubt, and has been confined mostly to those regions where such immigrants have settled. It prevails almost exclusively among them and the Kanakas, among the whites to a slight degree only.

In Tasmania, West Australia and South Australia there have been no cases, whereas in Victoria, New South Wales and Queensland, where there is a large Chinese population, there have been in the past forty years 146 cases observed. The disease is apparently not increasing rapidly.

The author is not a believer in the transference of leprosy by direct contact, but in the hypothesis that "the virus resides, not in man, but in his surroundings." The evidence he presents of its non-communicability by immediate association is wholly of negative character, just such as might be cited for a similar object with regard to the non-infective nature of syphilis or tuberculosis.

YELLOW FEVER: SERO-IMMUNIZATION AND
SERO-THERAPY.

As long as the sub-tropical Hispano-American countries to the south of us neglect sanitary precautions, or administer their sanitation as faultily as is now the case, yellow fever will continue to be a disease of more or less acute interest to us in the United States. Just now the interest is of the more acute character, both with the general and the business community and with the medical profession. There are two problems claiming the immediate attention of the medical mind, from both of which much profit might legitimately be expected.

The first, that of a national quarantine system administered by a central bureau or board, is not new, but is none the less pressing on that account, as recent occurrences in the States and towns affected by yellow fever have once again amply and forcibly demonstrated. A bill has been prepared, endorsed by both the American Medical Association and also by the American Public Health Association, which it is proposed to submit to the next United States Congress. We hope to say something once more about this problem in a subsequent issue.

The second problem, that of a sero-immunization and therapy for yellow fever is a newer one, but of hopeful solution. Its resolution would be of immense service to a national bureau of public health, and its service to humanity best secured by such an organization.

In the JOURNAL of July 22d and July 29th some account was given of Professor Sanarelli's announcement in regard to his investigations, pursued at the lazaretto of the island of Flores and the Hospital of Saint Sebastian in Rio Janeiro, into the pathogenesis and pathology of yellow fever, and of his claim to the discovery of a specific micro-organism which he described and named the *bacillus icteroides*.

Under date of July 24th, he now communicates from Montevideo a third memoir, which is published in the September-October fasciculi of the *Annali di*

Medicina Navale, a Roman periodical just received, and also in *Il Policlinico* of September 15th. This memoir treats of his further work upon immunity and sero-therapy against yellow fever. This memoir is divided into three parts: the first treats of the serum derived from yellow-fever cadavers and yellow-fever convalescents; the second of the immunization of animals against artificially produced yellow fever, the animals experimented upon being guinea-pigs, dogs and horses; the third of the sero therapy of artificially induced yellow fever.

Experiments with the blood taken from the hearts of cadavers from yellow fever very soon after death showed that it had no preventive power in respect to the specific bacillus. The serum of a convalescent from the disease produced the Grüber-Durham reaction with great slowness, and manifested a weak protective action in animals in respect to the bacillus icteroides. The simultaneous injection of the serum and the virus did not prevent the death of the guinea-pig, but death did not occur in the greater number if the injection of the serum in a dose of at least two cubic centimetres was practised twenty-four hours before that of the virus.

In his experiments on the immunization of animals against experimental yellow fever Sanarelli found that rabbits, goats and sheep were so sensitive to the living virus that he was obliged to confine his experiments to guinea-pigs, dogs and horses. The mortality, even in guinea-pigs, was so great that the immunization had to be conducted very slowly, requiring six to eight months. The dog could be made immune to minimum doses of the bacillus icteroides much more rapidly than the guinea-pig, but never became accustomed to multiple doses of the toxin. Severe vomiting and prostration were always induced by the endovenous injection of both cultures.

He found that the ox tolerated subcutaneous injections of the icteroid culture without the swelling and superficial sloughing which so often occurred in the case of the horse, but that both the horse and ox did not tolerate without serious reaction endovenous injections of the sterilized toxin.

A description of the technique of immunizing a horse is given, by which it appears that small doses of filtered cultures are injected subcutaneously, and as soon as the reaction from these, which lasts several days, is over, endovenous injections of filtered cultures into the external jugular are begun in small doses. These are at first well tolerated; but when the dose is increased, or cultures sterilized with ether, which are much more active, are employed, the animal shows signs of grave reaction, and frequently its life is in danger. For this reason the injections can be repeated only at long intervals, depending upon the rapidity of the recovery of the animal after each injection.

After about two months of the treatment by means of the filtered cultures, cultures simply sterilized with ether can be used; but it is not until five or six months after the commencement of the treatment that the first

injection of a small dose of the living culture can be attempted. This first injection causes a general reaction, lasting for ten days. The injection may then be repeated and the dose cautiously increased. The immunizing substances are produced only very slowly by the bacillus icteroides in the animal organism.

Professor Sanarelli describes his results in the sero-therapy of experimental yellow fever with the serum of guinea-pigs, dogs and horses. The accounts of the results with horses are of interest.

The first horse, the treatment of which was begun on July 24, 1896, died suddenly on February 14, 1897, after having received altogether in the space of about seven months 760 c. c. of filtered culture, two litres of sterilized culture, and 240 c. c. of living culture, although it was in excellent condition and had never been bled.

The second horse was placed under treatment on October 1, 1896, and on March 3, 1897, the serum from the first bleeding was found to have a weak preventive action against the yellow-fever infection in guinea-pigs, but to save a guinea-pig from the consecutive injection of a mortal dose it was necessary to inject twenty-four hours before the enormous dose of at least five cubic centimetres of the serum. The serum was not sufficiently powerful to cure the disease when it had already developed.

The inoculations with broth and gelatine cultures were continued, except when they had to be omitted on account of severe reaction, till July 1, 1897, when a second bleeding was practised, and the serum was immediately tested on guinea-pigs against mortal doses of virulent cultures. This serum conferred immunity if given twenty-four hours before in a dose of half a cubic centimetre and succeeded in saving guinea-pigs already ill even when inoculated forty-eight hours after in a dose of two cubic centimetres. These doses are still very far from representing the preventive and curative powers of the anti-amarylligenous serum, above all if one takes into consideration that possessed by other preventive and curative serums prepared up to the present time. These results showed that to obtain a good vaccination against the bacillus of yellow fever in animals is much more difficult and requires a much longer time than is ordinarily required with other species of known virus.

Professor Sanarelli concludes by expressing the opinion that very probably this same serum which saves animals that are destined to succumb almost without exception to experimental yellow fever will be of use in the treatment of spontaneous yellow fever in man; but he adds that it will be possible to verify this fact only when the more intensive immunization of the horse, then undergoing advanced treatment, should have furnished a serum more active in quantities sufficient to warrant the sero-therapeutic method being tested on diseased man.

In a footnote Professor Sanarelli states that the mortality from yellow fever varies from 13 to 90 per cent. according to the different epidemics and places.

In a second footnote he states that in the institute he has a second horse and two oxen which have been undergoing treatment for some months but whose serum he has not yet tested on animals.

A telegraphic despatch from Montevideo announces that Sanarelli gave a lecture there on October 13th on the sero-therapy of yellow fever, and expressed the hope that serum obtained from vaccinated animals would be efficacious for the cure of yellow fever in human beings.

MEDICAL NOTES.

PHYSICIANS FOR BOMBAY.—The Indian government has asked for twelve medical men to be sent out from England to the Bombay presidency for duty in the plague-stricken districts.

YELLOW FEVER IN THE SOUTH.—The yellow-fever situation has not improved during the past week, the cooler weather, although bringing hopes of an early frost, having rather increased the mortality. From 30 to 50 cases per day have been reported from New Orleans.

THE GERMAN SOCIETY OF NATURALISTS AND PHYSICIANS.—The German Society of Men of Science and Physicians will hold its meeting next year at Dusseldorf, under the presidency of Professor Waldeyer, of Berlin. The secretaries of the meeting are Professor Mooren and Dr. Von Viehoff, of Dusseldorf.

EXPULSION FROM A MEDICAL SOCIETY FOR UNETHICAL CONDUCT.—The Cumberland County Medical Society, at its semi-annual meeting at Bridgeton, N. J., on October 12th, expelled from its membership Dr. S. M. Wilson, a graduate of the University of Pennsylvania and a practitioner of twenty-eight years' standing, for unethical conduct in acting as physician for a company engaged in the employment of a proprietary cure for alcoholism. — *New York Record*.

OUR LUCRATIVE PROFESSION.—There are nearly four hundred doctors in St. Louis who are practically starving, says Dr. Lamphear, and in Brooklyn physicians are said to be hiring as motormen. Dispensaries and patent medicines are the alleged causes. — *The Medical Examiner*. [The mortality resulting from the Brooklyn electric is so notorious that it would have been in better taste for unsuccessful physicians to have entered upon some less fatal calling.]

MENTAL TREATMENT AND MENTAL REMUNERATION.—The action recently brought by two faith-healers in Baltimore to recover payment for their services in the "absent treatment" of a patient with pneumonia, who recovered under hospital care, has its humorous side. It is reported that one of these faith-healers testified that she and her partner (who was also her husband) had cured the patient of pneumonia by removing from his head the "unhealthy notion that he had pneumonia, and that the work of the physicians and nurses at the hospital had rather retarded than

helped the cure." The faith-healers had been retained in the case by the wife of the patient, without his consent, and sued to recover twenty-five dollars for their services. The decision of the presiding judge that, having given no apparent service to the sick they were for that reason not entitled to remuneration, reminds us of a case in which the same answer was phrased somewhat differently in a reply to a well-known Boston Christian Scientist's request for payment of her account. The patient is said to have reminded her that she had told him to imagine himself well, and he would be well. He therefore politely said that she had only to imagine herself paid, and she would be paid.

PROGRESS AT CRAIG COLONY DURING THE PAST YEAR.—The Craig Colony for Epileptics, at Sonyea, Livingston County, N. Y., closed its fourth fiscal year September 30, 1897. There were at that time 214 patients in the colony, the majority of whom had been transferred from the various county houses throughout the State. New buildings are in course of construction which, when completed, will enable the colony to accommodate 140 additional patients, making the total population about 350. It is estimated by State charity officials that this number represents about one-third of the total number of epileptics now on public charge throughout the State. The Medical Superintendent, Dr. William P. Spratling, reports a great increase in the value of agricultural and industrial products of the colony over last year, so that the ratio of earnings of the patients to the cost of their maintenance is even larger than that of last year, which was a little over fifty per cent. A laboratory for the use of a pathologist and pathological chemist is being constructed. Dr. Christian A. Herter, of New York, has been appointed pathological chemist, and Dr. Ira Van Gieson, of New York, consulting pathologist to the colony. Dr. Frederick Peterson, of New York, was re-elected President of the Board of Managers. The managers, at their annual meeting, decided to ask the coming Legislature for \$200,000 for dormitory buildings in order that they may increase the residence capacity of the colony for patients.

PLAGUE IN INDIA.—Plague is increasing in India. It is feared that it will break out somewhere in an epidemic form, and the necessity for active intervention occur. A telegram from Madras, under date October 16th, reports: "Three fresh cases, one has terminated fatally." "The appearance of plague," says the *British Medical Journal*, "at Madras is interesting epidemiologically, as we have no previous record of plague there. The cases, as far as we can learn, are imported cases merely, and in accordance with what we now know of plague, we should not anticipate an outbreak there in an epidemic form. A telegram of October 19th from Jullundur, a town in the Punjab, states that 23 deaths have occurred there 'from what is believed to be plague.' Jullundur is directly in the track northwards from Bombay, of the course the plague has followed previously. In the hospitals of

Poonah 294 cases of the plague are being treated, and the physicians are attending 115 cases in the Bombay hospitals. Whilst Poonah is relaxing her efforts by as far as possible annulling the severe segregation rules enforced when plague first appeared, Bombay is strengthening hers by imposing quarantine upon new arrivals. The period of detention will extend to six days, and accommodation will be provided for about 6,000 people. With the quarantine arrangements surveillance tickets are issued, whereby well-known people can avoid the quarantine on the understanding that they present themselves for examination on the third and sixth days after arrival. As well-nigh a third of the cases occurring in Bombay are imported, these regulations have shown excellent results. The inspection is rigid, and no person passed out has been known to have become subsequently attacked."

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, November 3, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 56, scarlet fever 25, measles 7, typhoid fever 24.

DEATH OF AN OLD ARMY NURSE.—Miss Rebecca Wiswell, who is said to have been the oldest army nurse of the Civil War, died in Plymouth, Mass., on October 29th, aged ninety-one. She was born in Provincetown, enlisted as army nurse in 1862, and served till the close of the war. She is reported to have made during her life 160 bed-quilts.

THE JOURNAL OF THE BOSTON SOCIETY OF THE MEDICAL SCIENCES.—The *Journal of the Boston Society of the Medical Sciences* has been enlarged to octavo size. By general consent of the Heads of Departments it will contain abstracts of experimental work carried on in the Medical School of Harvard University, the Experimental Laboratories of the Massachusetts General and the Boston City Hospitals, the Physiological and Biological Departments of the Massachusetts Institute of Technology and Clark University. It is proposed to issue the numbers of the Journal promptly after each meeting of the Society, and to give a rapid means of communication of the results of investigation. The intention is to publish at least ten numbers a year—running from October to June. The subscription price will be \$2.00 a year.

NEW YORK.

NEW BUILDINGS ON BLACKWELL'S ISLAND.—On October 28th Mayor Strong and the Commissioners of Public Charities celebrated the opening of eleven new buildings in connection with the almshouse on Blackwell's Island. Commissioner Faure said that at the time of his appointment over five hundred of the inmates were obliged to sleep on the floors, for lack of accommodation, and that many of those lodged in the top stories could watch the stars through holes in the roof which freely admitted the snow or rain in stormy

weather. There was no water in several of the buildings, and no lavatories, except makeshifts. Filth covered the floors until the physicians refused to enter one ward until it was cleaned. He then gave a report of the manner in which the Department have expended the million dollars which had been allowed them for improvements, stating that since January 1, 1895, no less than fifty-three new buildings had been erected. In addition to the eleven at the almshouse, these included fifteen at the Infants' Hospital on Randall's Island, five at Bellevue Hospital, four at City Hospital, Blackwell's Island, four at Fordham Hospital, the new Harlem and Gouverneur Hospitals, and the Lodging-house for Homeless Men. In delivering the keys of the buildings to the mayor, Dr. Stephen Smith, the new president of the Board, said: "Not one dollar of all that million has been spent for filagree or decoration, either on the interior or exterior." In contrast with the new kitchen was shown one of the old kitchens where soup, coffee, stews, potatoes and all other dishes were cooked successively in the same kettles; and a no less pleasing comparison was made between the new pavilion for blind women and the old one, the main floor of which rests directly on the ground, and the walls of which are of thin boards so loosely put together that in winter the inmates have always suffered greatly from cold.

A handsome and commodious new wing, erected at a cost of \$150,000, at St. Mary's Roman Catholic Hospital, on St. Mark's Avenue, Brooklyn, was recently dedicated. The new structure includes offices, a chapel, accommodations for Sisters of Charity acting as nurses, an operating department, and fifty additional rooms for patients.

The new Diphtheria and Scarlet Fever Hospital for pay patients, on the East River front at the foot of 16th Street, New York, has also been completed, and is now ready for service. The buildings consist of two brick pavilions, 88 by 28 feet, each of which contains ten wards and a department for convalescents, and is provided with a roof garden. The hospital cost \$100,000, which was contributed by a number of charitable ladies.

BEQUESTS.—In the will of Miss Caroline Talman, who died on October 20th, charitable bequests to the amount of over \$120,000 are made. Among the institutions named are St. Luke's Hospital and the Home for Incurables, each of which receives \$5,000.

THE LION INCUBATOR.—On October 24th a private reception for the medical profession was given at the Lion Institute, at Fifth Avenue and 18th Street, in order to afford an opportunity for the inspection of the ingeniously constructed incubator of Alexander Lion, of France, which seems to be by far the most perfect apparatus of the kind yet devised, and which has been approved by the Paris Academy of Medicine and the New York Obstetrical Society. It has been in use, with the most satisfactory results, in Nice since 1891, and the inventor has received for it a number of medals and prizes, the last being at the Nashville

(Tenn.) Exposition just closed. Among the special features of the incubator is the automatic regulation of the temperature, which can thus be maintained indefinitely at any required degree without the slightest variation. There are now at the Institute three seven months' children. The last of these was received on October 30th, and although it was born as long ago as September 7th, it weighed on admission only two pounds four ounces. Since the 25th the exhibition has been open to the public. No charge is made for the care of infants, but a small admission fee is charged for defraying expenses. At the present time the Lion incubator is being used for triplets at the Sloane Maternity.

ESQUIMAUX AND PULMONARY DISEASE.—It has been found necessary to remove six Esquimaux who were brought to New York by Lieutenant Peary a little over a month ago, and since then have been living in the building of the American Museum of Natural History, on Manhattan Square, to Bellevue Hospital on account of severe pulmonary disease. One of them, a woman forty-five years of age, has an attack of pneumonia which it is feared will prove fatal, and the others, three men and two children, are suffering from bronchitis. In Greenland, from where the patients came, such affections are said to be practically unknown.

DEATH FROM FOOT-BALL.—Andrew Hasche, a powerfully built young man of nineteen, died in the Astoria Hospital on October 26th from fracture and dislocation of the sixth cervical vertebra, the injury having been received in a game of foot-ball two days previous. Shortly before death delirium set in and his temperature went up to 112°.

MORTALITY AMONG CIVIC CANDIDATES.—During the recent municipal election canvass there has been a remarkable fatality among the candidates for office. The death of Dr. James P. Daly, candidate for coroner, has been already referred to. On October 29th Henry George died, and on October 30th Owen McGinnis, a veteran of the late war, who was a Democratic candidate for alderman. It is a curious fact, also, that all three deaths were due to cerebral apoplexy.

BIRTH OF A NEW PARTY.—While Mr. Joseph Choate was in the midst of an eloquent address at a large political gathering at Carnegie Music Hall during the campaign, he was interrupted by the chairman, General Swayne, who said to the wondering audience in the most solemn tones, "I am requested by the mayor to announce the birth of a new party." He then went on to explain that if a certain gentleman was in the hall his presence was particularly requested at home, where there had been an interesting addition to his family.

DEATH OF JOHN JONES, M.D.—Dr. John Jones, a prominent member of the Washington County Medical Association and a successful practitioner, died at his home at Middle Grauville, N. Y., on October 23d, of

typhoid fever. He was graduated from the Albany Medical College with honors, and was thirty-three years of age.

Miscellany.

THE CLINICAL VALUE OF THE WIDAL TEST FOR TYPHOID FEVER.

DR. W. GILMAN THOMPSON, having gathered data regarding the Widal serum-test for the presence of typhoid fever from five of the larger New York hospitals, publishes his results in the *Medical News* (October 30th), and reaches the following conclusions:

(1) While the test is positive in the large majority of cases of enteric fever, and negative in the greater number of other diseases, there is a margin of error of 11 to 12 per cent. on each side of what might be called the normal line, between cases in which the test fails where it ought to succeed and succeeds where it ought to fail, in order to make it of real clinical value.

(2) This total of 23 per cent. of possible error includes unfortunately just those cases in which there is the greater doubt upon the purely clinical side.

(3) As a genuine diagnostic aid the test has about the value of the Diazo reaction in typhoid urine, or the study of leucocytosis in pneumonia; that is, it is confirmatory in connection with appropriate symptoms but misleading if positive reliance be placed upon it.

(4) The fact that an expert bacteriologist is required to make the test is offset by the ease of transportation of specimens of dried blood which long retain the power of reaction, and it is greatly to be hoped that a further possible improvement in technique may place this most ingenious test upon a firmer practical basis than can at present be claimed for it.

STARVATION OF RECONCENTRADOS IN CUBA.

DR. BRUNNER, medical inspector of the United States Marine-Hospital Service in Havana, writes in the latest report: "An inspection of a pest hole, known as Los Fosos, was made by me on Thursday, October 14th. This place has been set aside for the country people sent to Havana. Los Fosos consists of a large wooden building, about 150 feet in length and 60 in width. The building is situated in an inclosure which is used for the storing of carts of the municipality. There were 500 people found in and around this building, and of that number over 200 were found lying on the floor, sick and dying. I saw no child under ten years of age who could be considered in good health. They were invariably suffering from some form of enteritis or dysentery. The emaciation of their bodies was startling. This place is not a hospital, but simply a place of residence for these people, and a conservative estimate of the death-rate would be about 10 per day. The number is recruited by fresh accessions from the country. There were over 150 children below the age of ten years, and I did not observe one whose chance for living thirty days, under the existing conditions, was good. There are two other such places in the city where the same conditions exist."

The hospitals of the city are frightfully overcrowded, the death-rate is increasing; and the sanitary conditions, already bad enough, are becoming constantly worse.

ILLINOIS TO RAISE THE STANDARD OF ADMISSION TO PRACTICE.

At the regular quarterly meeting of the Illinois State Board of Health, held at the Great Northern Hotel, Chicago, October 5, 1897, the following resolutions were passed:

Resolved, that after May 1, 1898, all non-graduate applicants for license to practice medicine and surgery who are examined in accordance with the provisions of the Medical Practice Act, in addition to the requirements already exacted, must present as evidence of satisfactory preliminary education, either,

(1) A diploma or certificate of graduation from a high school.

(2) A certificate of having passed the matriculation examination to a recognized literary or scientific college.

(3) A certificate of successful examination by the faculty of any reputable university or college of arts or science (not members of a medical college faculty), by the State Superintendent of Public Instruction of Illinois, or by the principal of a high school in Illinois, in the following branches: English Grammar, Arithmetic, Elementary Physics, United States History, Geography and Latin (equivalent to one year in a high school).

Each candidate will also be required to present a certificate from a medical college in good standing with this Board, attesting that the applicant has,

(1) Pursued the study of practical anatomy in said college for at least one term, and has made dissections of the entire cadaver.

(2) Taken at least one full course in operative surgery and practical obstetrics.

(3) Personally attended six or more cases of labor.

Bacteriology has been added to the subjects of the non-graduate examination.

Correspondence.

BERLIN LETTER.

INTERNATIONAL CONGRESS OF LEPROLOGY.

BERLIN, October 16, 1897.

MR. EDITOR:—The International Leprosy Conference held its sessions here all this week. The management of it has been excellent throughout, and the interest shown in it by the German Government contributed greatly to its success. The members were received by the Chancellor on Tuesday evening, and by the Kaiser and Kaiserin at the New Palace in Potsdam on Friday evening. A reception of welcome was given by the President of the Organization Committee, Professor Lassar, and his wife, on Sunday evening, and the Dermatological Society invited the members to be its guests on Thursday evening. The Berlin Club asked the members to consider its rooms as their own during their stay, and tickets for the Imperial Opera House and Theatre were placed at the disposition of the members during the week.

It is said with a good deal of enthusiasm by the departing guests that Berlin is the place for International Scientific meetings, at least under such auspices as the Leprosy conference was held.

A number of prominent leprologists and dermatologists were present from all over the world: Hansen, from Norway; Arning, from Denmark; Neuman and Kaposi, from Vienna; Unna, Lassar, Neisser, from Germany; Petersen, from Russia; von Düring, from Constantinople; Carrasquilla, from Columbia; Besnier and Hallopeau, from Paris. The proceedings were of special interest, as being an index of the present state of medical knowledge as regards leprosy, and the trend of thought with regard to the solution of questions that are still *sub judice*.

Professor Virchow acted as president of the Conference,

and his contribution to the proceedings was a talk on the question of "Pre-Columbian Leprosy in America." He considers it almost demonstrated that the mutilations to be seen on certain pieces of pottery found in Peru point to the existence of leprosy in America before Columbus's time. He knows of no other disease that would cause the mutilations of the feet that are found in the figures, and while the facial mutilations are rather those of lupus than leprosy, yet he was able to show by comparison with certain figures in Professor Lassar's collection that such mutilations may occur in leprosy too.

With regard to the question of contagion or heredity, there was almost unanimity. A few of the Eastern leprologists still consider that heredity plays a great rôle in the etiology of leprosy; and one distinguished authority, Professor Zambaco Pacha, of Constantinople, insists that it is the important factor; but all other members of the Conference were frankly outspoken contagionists. There was another exception: a paper from Jonathan Hutchinson, of London (he was indisposed and unable to be present), insisted on the importance of fish, especially salt fish, in certain stages of decomposition.

Everybody admitted Hansen's bacillus as the cause of the disease, and some startling observations were published as to the enormous number of the bacilli that are given off by the patient, especially in oral and nasal secretions and in epidermal scales. Stricker, of Giessen, found bacilli in the nose of 140 out of 153 patients examined; and from Neisser's laboratory in Breslau it was reported that lepra bacilli have been found one and one-half metres from where a leper sat and talked for an hour, while thousands of them could be found on a cover-glass held some distance in front of the patient while he talked. Its power of infecting others is extremely limited, otherwise more frequent contagion would be noted. Association with lepers for years and very intimately is necessary to allow of the conveyance of the contagion. In fact, there would seem to be a special condition of lowered vital resistance necessary, and of this nothing is known. While the mediate cause, the bacillus, is admitted, the immediate personal reason why a particular person acquires leprosy is as much a mystery as ever.

As to the necessity for the demonstration of the bacillus for the diagnosis of leprosy, opinions were divided. Kaposi showed some colored plates of cases of papular leprosy which he thought so characteristic clinically that even though he was unable after repeated examinations of bits of excised tissue to find the bacilli, he considered the diagnosis of leprosy justified. Hansen, after an examination of the plates, pronounced the cases not to be leprosy. Arning considered them very doubtful. The French school agreed that they were not at all typical cases, and in the absence of the bacillus considered the diagnosis scarcely justified. Unna thought they were leprosy; and it is in these cases that the bacillus may be best found by his new technique. In general, it seemed to be thought that diagnosis should be very guarded until the bacillus is demonstrated.

As to the question of the bacillus of leprosy ever being found within the cells, Unna maintained, against the world, that it never occurred. A large number of preparations were shown in which the bacilli seemed to be within the cells, but he explained them as optical illusions, the bacilli really lying above in the lymph spaces. After looking at a number of the preparations, Virchow said during the recess that he considered it demonstrated that the bacilli were intra- and extra-cellular.

As to syringomyelia and Morvan's disease the opinion was very freely expressed on all sides that many of these cases are to be viewed with suspicion. Two cases were exhibited that had been under treatment in nervous clinics here in Berlin as syringomyelia, which distinguished leprologists pronounced lepra. Zambaco Pacha and the Eastern school generally insist that scleroderma and sclerodactyly and Raynaud's disease are also often manifestations of leprosy, and that in general sporadic cases of leprosy are constantly turning up in the West, which remain unrecognized because of unfamiliarity with the disease.

As to therapy, very little seemed to be hoped for from it. Injections of soluble salts of mercury and of iodine do good temporarily; and it was the thought that, as in syphilis, the application of the treatment whenever recurrences came on was the best that could be done pharmaceutically for the patient. None of the serums have given results except in their inventor's hands. The action of Dr. Carrasquilla's serum has been so different here in Europe from that which he has reported himself that he thinks some chemical change takes place in it during the long transportation. His own results and those of colleagues in Columbia continue to be good. It is not guaranteed to cure, but it greatly alleviates the symptoms and retards the course of the disease. Professor Dyer's (New Orleans) preliminary report of use of antivenine serum obtained from animals after inoculation with snake venom attracted a good deal of attention from its novelty.

In general, however, it was agreed that the thing that should occupy medical attention is the prevention of the further spread of the disease to others. This is best accomplished by isolation of the lepers; and Professor Hansen's resolution to this effect was adopted without a dissenting voice. Circumstances will alter the manner in which this will have to be accomplished; but absolute segregation would, it is thought, absolutely eradicate the disease in a generation or two. This is called to the attention of the government, and suggestions offered as to how it is to be carried out.

A committee to organize a leprosy society was appointed; and the next meeting will be held either at Paris or Berlin, in 1900, both places giving cordial invitations.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, OCTOBER 23, 1897.

Newburyport .	14,794	5	1	—	—	—	—	—	
Amesbury . .	10,920	—	—	—	—	—	—	—	

Deaths reported 2,580; under five years of age 835; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 350, consumption 302, acute lung diseases

289, diphtheria and croup 124, diarrheal diseases 112, typhoid fever 60, scarlet fever 21, whooping-cough 13, cerebro-spinal meningitis 10, measles 6, erysipelas 3.

From scarlet fever New York 8, Philadelphia 3, Brooklyn, Baltimore and Pittsburg 2 each. From whooping-cough New York 3, Philadelphia, Brooklyn, Boston and Cincinnati 2 each, Baltimore and Washington 1 each. From cerebro-spinal meningitis New York 4, Boston, Washington, Worcester, New Bedford, Somerville and Woburn 1 each. From measles New York 4, Philadelphia and Brooklyn 1 each. From erysipelas New York 3.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending October 16th, the death-rate was 16.9. Deaths reported 3,566, diarrhea 127, measles 89, diphtheria 73, fever 51, whooping-cough 39, scarlet fever 36.

The death-rates ranged from 9.2 in Cardiff to 23.7 in Birmingham; Bradford 13.8, Bristol 16.2, Croydon 11.6, Gateshead 21.2, Hull 15.1, Leeds 16.6, Leicester 12.8, Liverpool 22.4, London 16.1, Manchester 28.8, Newcastle-on-Tyne 18.7, Nottingham 17.0, Sheffield 17.8, West Ham 12.0.

METEOROLOGICAL RECORD

For the week ending October 23d, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 23, 1897, TO OCTOBER 29, 1897.

MAJOR W. C. SHANNON, surgeon, sick leave of absence further extended six months.

LIEUT.-COL. CHARLES SMART, deputy surgeon-general, and CAPTAIN WM. H. ARTHUR, assistant surgeon, are detailed to represent the Medical Department of the Army at the twenty-fifth annual meeting of the American Public Health Association, to meet at Philadelphia, Pa., October 26 to 29, 1897.

FIRST-LIEUT. THOMAS J. KIRKPATRICK, JR., assistant surgeon, is granted thirty days' extension to leave of absence.

MAJOR ALFRED C. GIRARD, surgeon, is detailed as a delegate to represent the Government of the United States at the Ninth International Congress of Hygiene and Demography, to be held at Madrid, Spain, April 10 to 17, 1898.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE TWO WEEKS ENDING OCTOBER 30, 1897.

W. K. VAN REYFFEN, medical director, detached as member of Board of Inspection and Survey and made chief of Bureau of Medicine and Surgery.

T. W. RICHARDS, assistant surgeon, detached from the "Maine," ordered home to Washington, and granted two months' leave.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE NINETEEN DAYS ENDING OCTOBER 26, 1897.

BAILLIACHE, P. H., surgeon. To represent Service at meeting of American Public Health Association at Philadelphia, Pa. October 26, 1897.

IRWIN, FAIRFAX, surgeon. To represent Service at meeting of American Public Health Association at Philadelphia, Pa. October 26, 1897.

CARTER, H. R., surgeon. To proceed to Montgomery, Ala., for special temporary duty. October 25, 1897.

WHITE, J. H., passed assistant surgeon. To proceed to Camp Hutton, La., for duty. October 11, 1897.

SOCIETY NOTICE.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.—The tenth annual meeting will be held at the Southern Hotel, St. Louis, Mo., on November 9, 10 and 11, 1897. Members of the medical profession are cordially invited to attend.

W. E. B. DAVIS, *Secretary*, Birmingham, Ala.

BOOKS AND PAMPHLETS RECEIVED.

Lumbago. By Francis Reder, M.D., Hannibal, Mo. Reprint. 1897.

Address.

SCIENCE IN MEDICINE.¹

BY A. T. CABOT, A.M., M.D., BOSTON.

GENTLEMEN: — I shall not enlarge on the fact that you are entering on a noble profession. That statement is often heard and has a good deal of truth in it; but the important thing for us to remember is that our profession is as noble, for each of us, as we ourselves make it, and no more so. It behooves us then to carry with us the resolve that we will do our utmost to sustain the high ideals of the past and to reach still greater heights in the future. In carrying out this purpose we shall have to turn often from the promptings of self-interest, and shall have to make sacrifices to our love of truth and to our sense of duty. Let us not be too vainglorious, however, over our sacrifices, for they are usually only such in seeming. Our voyages of discovery, like those of the old Spaniards, lead us often to where gold is to be had for the delving; and the medical man who devotes himself to the cause of science reaps his reward in this world in the added prestige and lustre which his attainments lend him. His light then so shines that men are attracted to him, and they see that he does not want.

This may seem a sordid consideration; and if it is allowed to be the mainspring of action, it indeed becomes so. There are many better and more inspiring inducements than this to incline right-minded men to scientific pursuits; but every prudent man must consider his own support and that of those dependent on him; and such a man may well feel encouraged to give time to seemingly unremunerative research if he believes that the knowledge and habits of thought which such research brings him will have a market value at some later date and that the prestige of any good work that he may do will help him in his future career. A proper appreciation of these truths may encourage some of you to seek success by a devotion to science rather than by the pursuit of business. I venture to predict that few who are thus inclined will regret it.

It is about science in medicine that I wish to say a few words to you to-night, in the hope of emphasizing to you some of the gifts you have received from her and the duty you owe to her in return, and also with the desire of pointing out to you some of the ways in which you may serve her.

It is but as yesterday that medicine has become a hand-maiden of science and has escaped from the domain of inexact empiric art. So recent is this advance that the most important steps of it have occurred within the memory of one generation.

Do not understand me to belittle the achievements of past centuries nor to imply that we have already reached the goal of exact knowledge towards which men have always been striving. But I do assert that in the past fifty years advancing medical knowledge has taken up more new ground than all of that occupied before, since our earliest authentic records.

How has this come about? Have the men of the last half of the nineteenth century been so much superior in intelligence to their fathers as to accomplish this? No! But their powers of research have been increased many hundred fold; and this advance

tage they owe to the physical laboratory, for it is the microscope which has revolutionized medicine and has made it possible for us to stand where we now do.

It enables us to see clearly where all was once dark groping, and to penetrate mysteries before which past ages have stood blind and uncomprehending. Let us not forget our gratitude to the physicists, who have made this possible. They are busy people, these physicists, and their modern achievements have been so wonderful as to have almost exhausted our capacity for wonder.

A man sitting in his chair here in Cleveland talks with his friend in New York, and even recognizes that friend's voice over a thousand miles of wire. He reads each morning in his daily paper an epitome of what the human race has accomplished in the past twenty-four hours, a chronicle of the doings in the uttermost parts of the earth, and even shrewd suspicions of the happenings in some of the neighboring planets. Marvels which to a past generation would seem miracles are his daily bread, and he misses an accustomed stimulus if they are not constantly supplied and are not up to a high standard.

In an age of such enormous activity it is well to remember that our pioneers along the various roads of investigation have accomplished their results by concentration of effort and by the assertion of their own individuality. It is by the possession and exercise of these qualities that we must endeavor to carry forward their work. Every man must be more or less a specialist.

Even Bacon would hardly, at this time, claim all knowledge as his province; and we of lesser gifts must realize our limitations, and by attending strictly to labors that are within our strength, and by applying all of our powers to them, must endeavor to reach worthy results.

I do not use the term specialist as implying a narrow field. A man who practises surgery to the exclusion of general medicine is a specialist; and if his tastes and opportunities lead him especially into some branch, as gynecology or abdominal or orthopedic surgery, he still further specializes his work. This I regard as the best way to approach a specialty: beginning with the general and working gradually more and more into special branches. In this way one is more liable to take a large grasp of his subject and to acquire the habit of looking at his patient as a whole, before allowing his attention to be drawn to the close study of a particular organ or region.

The various fields of study touch each other at so many points that we cannot occupy ourselves in one without coming in constant contact with those about. The surgeon studying a brain tumor requires the services of a neurologist and perhaps of an ophthalmologist and aurist before he can arrive at the best knowledge of the case. It is well that we should get the habit of thus using each other to help us to greater accuracy and efficiency. While travelling thus our own road, we shall get and give many a lift if we are so minded.

The generation now growing old has, in this country, been the one which has seen the various specialties of medical practice evolved. Fifty years ago the general practitioner was the rule, the specialist was the rare exception. I remember many of those old "family doctors," learned, sagacious, observant, friendly advisers and confidants, with an academic dignity which has

¹ An Address to the graduating medical class of the Western Reserve University.

been almost lost in the hurry and bustle and matter-of-fact directness of the last half-century. To follow one of these men through his daily rounds would be a curious experience to a modern specialist.

The first case, perhaps, would be a broken leg, then a pneumonia or dysentery, an ophthalmia, a middle-ear inflammation, a confinement and a case of mania. To each of these various cases he would apply himself with trained powers of observation, often noticing and getting guidance from slight physical signs or movements of the patient which now pass unnoticed by the modern clinician. For the latter, with his instruments of precision, his clinical thermometer, his modern stethoscope, his stomach-tube, his specula, his blood-count and various other microscopical examinations, has more certain guides to a correct opinion, and does not need observation of the lighter straws to see which way the wind blows.

A student of to-day looking back at the generation of medical men who finished their work in the sixties is struck with the amount of empiricism that pervaded the best medical practice of those days. It was an empiricism not of choice but of necessity, for the field of vision was so limited for them that they had to do much blind groping among conditions but partly seen and imperfectly understood. The groper in the dark greatly sharpens his vision for what comes within the range of his sight, and it is surprising how many facts they discovered, the reasons for which were learned much later. Quinine, for instance, was given on correct principles in the treatment of intermittent fever long before the plasmodium was discovered; and subcutaneous tenotomy was put to valuable use for years before its immunity from harm was explained.

The discovery of vaccination and of surgical anesthesia are brilliant examples of the acute observation and the bold inductive reasoning with which the men of those days pushed out beyond the lines of safe navigation into the unknown, and brought back treasures from regions now somewhat explored, but then veritable *terra incognita* beset with dangers real and imaginary.

But a light was soon to break.

It was during this time that the foundations of modern medicine were being laid, not upon any therapeutic dogma but upon the firm bed-rock of cellular pathology and bacteriology.

Gentlemen, we owe much to the European Continent, from which we all came; and not the least of our debts is to the laboratory system of Germany and France in which this great medical revival of our day started.

In this country the facilities for scientific study and teaching were not then highly developed. Hospitals and laboratories were few, and the man wishing to pursue original investigations in the higher branches of medicine had to be first assured of an independent income; for salaried positions were scarce and the stipends were small.

Under the paternal governments of the Old World learning had secured more substantial appreciation and support. Great schools of medicine had grown up in the capitals and large cities of the European States, and the rivalry which existed among them had called into existence a great body of scientific workers striving for the high places and stimulated by the hope of advancement to put forth their best efforts along original lines. No man holding a professorship in

Innsbrück was content to fold his hands and accept a routine of teaching if he felt within himself the ability and force to win a place in Munich or Vienna, and these places were to be won only by brilliant individual achievement.

Such was the system under which men like Virchow, Billroth, Cohnheim, v. Recklinghausen and a host of others were reared. Under it they were encouraged to put forth their greatest strength in pushing their researches; they were stimulated by constant contact with other investigators working along the same or parallel lines. The very atmosphere in some of those old universities became so loaded with scientific impulses that to breathe it was an inspiration. The visitor there found himself acquiring habits of thought without knowing whence they came. Accustomed to well-trodden paths, he found himself seized with the irresistible impulse to plunge into hidden byways and to do some exploring for himself. Every one seemed to have adopted the motto of the mongoose family as set forth by Kipling, "Run and find out."

If Americans of that day could not manufacture for themselves equally favorable conditions for study in this country, they knew at least where to find them, and the foreign clinics were filled with young men who had crossed the sea to put their guessing and calculating faculties under better guidance than they had been able to find at home.

And when these young men came back they came filled with a reverence for scientific methods and thought in medicine which could not and did not fail to make an impression in the communities in which they afterwards lived; and this leaven thus introduced into our country has worked, and to-day we see the awakened sentiment for higher medical education causing laboratories, workshops of science, to spring up in every direction, and to-day we are just getting into shape to take our place shoulder-to-shoulder with our older brothers abroad.

This growth of laboratories in America has been mainly accomplished by benefactions and gifts to learning from private citizens who have shown their sagacity and intelligence, first, in the acquisition of wealth, and then in the wise disposal of a part of it so that it may contribute to the highest public good. It is by a wide demonstration of the value of the best scientific teaching that the public interest will be so aroused that these gifts shall flow to our colleges in still greater abundance, and shall enable us to establish ourselves on an even higher plane of usefulness. Each of us may help the public towards this appreciation of the value of science in medicine somewhat by preaching, but still more by our practice. Fortunately the scientific exactitude of the laboratory has begun to bear fruit in the practice of medicine that every one but the hopelessly color-blind can see. Every case of diphtheria saved by the judicious use of antitoxin is an object-lesson that cannot be overlooked.

The man, who, in a case of difficult diagnosis establishes the existence of malaria by the finding of the plasmodium in the blood, or of typhoid by the serum reaction, demonstrates the supremacy of scientific over empiric medicine and exerts a healthy influence on the minds of the surrounding community. Presently he will open their eyes to the immense importance of fostering a study which may have for them such beneficial results. Let us apply our shoulders to these wheels, that they may move forward.

These are some of the ways in which, under our democratic form of government, we may properly influence the public purse to open to the cause of medical progress in America and to supply the sinews which will enable us to keep well up in the race. This is a generous rivalry. The ground gained becomes common property: no one can get ahead without pulling the rest along after him, and those that cannot pull must push.

But this educational effect which may be exerted on the community by a physician using exact scientific methods in his practice is an incidental public advantage, less important, as far as he individually is concerned, than the effects produced upon himself.

There is a constant force acting on the body medical, impelling it to seek easy running grooves, or, if you will, ruts. A busy practitioner adopts a routine to save himself thought and the expenditure of force. While he may, in the majority of cases, correctly diagnose the disease and properly treat it according to established methods, he cannot hope under such a plan to make any substantial improvement in his practice or to add anything to the knowledge of the diseases that come under his eye. Unusual cases do not arouse his interest, and rare diseases are unrecognized, or classed with some more common ailment which has somewhat similar symptoms. To such a man much of the pleasure of medical practice is wholly lost, the joy of discovery is to him unknown. Even though his practice embraces the whole range of medicine and surgery, he remains essentially narrow.

You will hear much of the narrowing effect of a specialty; and it is true that a specialty selected for business reasons, because there seems to be an opening in it, and pursued in this spirit, will have a narrowing effect. But a special line of work into which a man grows because he has a taste for it, and which he pursues in a scientific spirit, will lead him into far wider fields of thought than those which open before the routine general practitioner.

Therefore, I say to you that your profession will be satisfying and absorbing in proportion as you pursue it as a science and not as a business; and it is also true that the same course will lead you forward into the front ranks of those "practising physic."

It will happen to many of you to be so situated that time and opportunity are lacking for microscopical and chemical work, and this may seem an adequate excuse for relaxing the exactitude of your study. But it is not so, if, within accessible distance, you can find any one who can help you out and do some of this work for you.

A young man, fresh from the laboratories, can in this way be of the greatest assistance to his busier brother; and the older man by thus employing the junior gives him opportunity and stimulus for further research. The laboratories, too, are greatly aided by this constant demonstration of the value of their training. Perhaps in no branch of medicine is this kind of help more needed or of more value than in surgery; and I can use it best in illustration, for of it I am most competent to speak.

A surgeon approaches a doubtful tumor of the breast. If it is of benign character it can be removed with comparatively little deformity, whereas if in any part of it a malignant change has commenced, the operation demanded is extensive, mutilating, involving not only the removal of the whole breast and per-

haps the underlying muscle, but also the dissection of the axilla and possibly of the supra-clavicular space.

For a wise decision in such a case as this, the prudent man requires the assistance of a trained microscopist versed in surgical pathology, who shall make careful search throughout the primary tumor to determine the presence or absence of any malignant part in it. Such a search, to be of the greatest use to the patient, must be made on the spot at the time of the operation, so that the information gained may be put to immediate use in determining the extent of the operative procedure.

The patient has a right to demand such care in a matter which may be for her a question of life or death; for an operation done thoroughly on a malignant growth so small that its detection is difficult offers considerable chance of a lasting cure, while an incomplete operation done at that time may leave a commencing glandular infection untouched until too late. In other forms of malignant growth a careful pathological supervision of the operation may detect the extension of the morbid process in unsuspected directions and enable the surgeon's knife to circumscribe it by the removal of parts seemingly healthy but in reality already infected.

Here is a field, then, in which surgeon and pathologist should work side by side; and the surgeon by insisting on this co-operation not only enhances the value of his own work but also brings into due prominence the work of his scientific brother.

A slight consideration of the debt that surgery owes to bacteriology will make plain the importance of the daily employment of the bacteriologist in the study of our surgical cases.

The practical application of the germ theory to the combating of disease has reached more tangible results in surgery than in any other department of medicine. "So great an influence has this theory had upon our successful practice that we are compelled to look upon the last quarter of the nineteenth century as the surgical golden age."

The discovery that the cause of inflammation in wounds is a preventable one has robbed surgery of the uncertainty and dangers that before prevailed, and has opened to the surgeon's knife regions and organs previously regarded as sacred. I well remember the time when an opening into the peritoneal cavity was regarded as a practically fatal accident, while now we open it without a thought of danger.

At present a knowledge of bacteriology enables the surgeon to test his antiseptic methods and his materials, and to thus keep a watch upon his technique, which is most necessary to his success. He also is often helped greatly in prognosis by an accurate knowledge of the organisms which are responsible for an inflammatory process that he is dealing with.

Whether a further study of acute inflammations will enable us to attack a process already started with an appropriate antitoxic serum cannot now be predicted, but the success attained in diphtheria must make us hopeful, and should lead us all to give close study to our cases. Even if we cannot hope to ourselves contribute to the advance in this direction, we shall at least accustom ourselves to an accuracy of mind in considering inflammatory conditions which will prepare us for making prompt use of any discoveries made elsewhere.

The man who is in the habit of watching the strep-

tococcus, the staphylococcus, the pneumococcus and other microbes, and of studying their various effects upon his patients, will also put himself in a position to make immediate and intelligent use of any new method of treatment directed against one or other of these organisms.

In the recognition and study of tuberculous processes the aid that the bacteriologist gives the surgeon is constant and valuable.

Whether future researches will put any of the malignant growths into the category of germ diseases cannot at present be told. There seems at least some reason for such a hope. Were this to prove true, the prophylaxis or cure of these dreaded conditions might be made possible. If such good fortune seems remotely possible, it is worth striving for with all the force that is in us, as it will only be reached by the combined work of the surgeon and the pathologist. Let every practising surgeon give what aid he can to the cause of scientific medicine, and so help towards this beneficent result. Who knows that we may not live to see cancer brought into the category of preventable diseases.

Any mention of the debts of surgery to laboratory research would be incomplete which stopped with an enumeration of the triumphs of the microscope that gives us such insight into dead tissues and enables us to read the histories within them, for we are still glowing with the enthusiasm awakened by the discoveries of Röntgen and his co-workers, who have taught the human eye to penetrate living tissues and to see, as by the light of day, conditions heretofore concealed from us.

It is still too early to say how far-reaching the effect of this new power will be upon our surgical practice, but the results already obtained are of the greatest value, and the constant improvements in this method of research are opening up wider and wider fields of usefulness. It is well to notice that this again is a benefit which, like the microscope, has been conferred upon the physician by the students of pure science, and is a capital illustration of the manner in which scientific workers in wholly different fields constantly come to each other's aid in ways quite unexpected. Such is the brotherhood of science.

I have indicated very hastily and imperfectly some few relations of science to medicine and some of the duties we should perform in her behalf and our own. The particular illustrations I have used are but a few of those which will occur to you all; for the effort after accurate observation as a basis for medical practice has been a tremendous stimulus to human ingenuity and has called into existence innumerable devices to enable the senses to penetrate beneath the surface of the body. Chemistry has been called to our aid in the investigation of organic functions. Various optical devices enable us to inspect the interior of the more accessible cavities of the body; and the acoustical properties of other deeper cavities have been carefully observed and have been put to good use in diagnosis. The trained physician must have all of these methods of research under his control, and must put them to constant use.

In some practical applications of medical science America has already taken a place in the first rank. The Boards of Health in many of our American communities have done much good work in the prophylaxis

of disease. They have shown great intelligence in making efficient use of facts discovered in the laboratory. The value and methods of a proper quarantine, the isolation of contagious cases, the scientific study of the water-supply of towns great and small, the disposal of sewage, are all questions upon which our American investigators have made their mark. They are questions in which every practising physician should take a keen interest, and in which he should lend a hand, both by the continued investigation of them and by exciting and guiding an intelligent public interest.

Preventive medicine, much as it has accomplished, is in its infancy. Think of some of the problems just opening up to us in this field. Tuberculosis, typhoid fever, the eruptive fevers, diphtheria, are all diseases which love a crowd and which grow by what they feed on. The constantly increasing density of population favors their spread; and unhindered their devastations might be expected to increase in a rapidly accelerating ratio. To what extent this increase may be met and successfully combated is not easy to say. It is, however, certain that since the discovery of the microbic origin of these diseases we see reason to pluck up fresh courage and to hope that a clearer understanding of the conditions under which the organisms enter the body and of the forces by which the tissues resist their invasion will enable us to wage a more equal battle against them.

Every medical man in America should give all assistance in his power to the health authorities about him. If they are trying to carry out thorough systems of isolation of disease, he should aid them in making the isolation as complete as possible, and bringing all the contagious cases possible under their observation. It often becomes the duty of the private practitioner to investigate the cause of disease and the manner in which it has spread. When a man has made a diagnosis of typhoid fever and has put the patient upon a proper course of treatment, his duty to the patient is done, but his duty to the community is just beginning. He should first protect the family and the neighbors from a possible spread of the disease from his patient. After this has been provided for by thorough disinfection of the excreta and clothing in contact with the patient, he is still neglectful if he does not make every effort to discover and remove the source of the poison which brought his patient down.

When all of these duties are done, and not until then, can he claim to be a scientific practitioner of medicine. When such a man does all of these things habitually, the community in which he lives must be ungrateful if they do not recognize him, not only as the wise and skilful physician, but as the conscientious public servant and friend.

He is a man to whom the public will always turn in case of need, and whose power for good service to mankind will be limited only by his strength. Scatter such men broadly through this country, and the universities and schools that educate and inspire them with such aims will never lack for support. Scientific medicine will see friends and benefactors growing up on every side, eager to help in a cause where success means a constant gain in universal health and happiness.

DURING the first six months of 1897, 8,232 medical students were enrolled at the German universities.

Original Articles.

THE PUBLIC CARE OF THE INSANE IN MASSACHUSETTS.¹

BY J. L. HILDRETH, M.D., CAMBRIDGE, MASS.,
*Professor of Clinical Medicine, Tufts Medical School; Member of
 State Board of Lunacy and Charity, etc.*

(Concluded from No. 19, p. 465.)

Of the management of the regular insane asylums, the Memorial makes no criticism. On the contrary, it mentions numerous instances of patients who had been temporarily committed to asylums with great benefit, and whose relapse on their return to the local jail or almshouse bore pitiful witness against the niggardliness which had occasioned it. "At Springfield, in the jail," says the Memorial, "is a lunatic woman, furiously mad, improperly situated both in regard to the prisoners, the keepers, and herself,—a case of extreme self-forgetfulness and oblivion to the ordinary decencies of life. She is much worse since leaving Worcester." At Newton, in the almshouse, in charge of a crippled, old negro pauper, quartered in a woodshed of which he occupied one small room and she the other, "a woman, not old, and furiously mad. Inexpressibly disgusting and loathsome was all, but the inmate herself even more horribly repelling. She rushed out, as far as her chains allowed, almost in a state of nudity, exposed to a dozen persons, and pouring forth such a flood of indecent language as might corrupt even Newgate. I entreated the man, who was still there, to go out and close the door. He refused; that was his place. The young woman was the child of respectable, hard-working patients. She became insane; the father, a farmer with small means from a narrow income, had placed her at the State Hospital. There she remained as long as he could by any means pay her expenses. Then, and then only, he resigned her to the town,—to those who are, in the eyes of the law, the guardians of the poor and needy: she was placed with the other town paupers, and given in charge to a man."

At Danvers was "a young woman exhibiting a condition of neglect and misery blotting out the faintest idea of comfort, and outraging every sentiment of decency. She had been at Worcester Hospital for a considerable time, and had been returned as incurable. The mistress told me she understood that while there she was comfortable and decent."

There are frequent references, also, to cases which might have improved under hospital treatment, if it could have been provided. At Dedham, in the almshouse, are noted, "two females in stalls situated in the main building, lying in wooden bunks filled with straw, always shut up, one of them supposed curable. Overseers of the poor, as I was informed, have declined giving her a trial at the hospital on account of expense."

With admirable forbearance and discrimination, Miss Dix points out that it is not so much the keepers of the local jails and almshouses who are to be blamed for the horrors discovered as the system which entrusts to their care those whom they have no proper facilities for housing, much less treating. She gives letters in abundance from wardens and sheriffs to prove that they regard the introduction of the violently insane as most demoralizing to their establishments, and would welcome any charge by which they could be relieved of them. "I would speak as kindly as possible,"

she says, "of all wardens, keepers, and other responsible officers, believing that most of these have erred, not through hardness of heart and wilful cruelty, so much as want of skill and knowledge, and want of consideration. Familiarity with suffering, it is said, blunts the sensibilities, and where neglect once finds a footing other injuries are multiplied. This is not all, for it may justly and strongly be added that, from the deficiency of adequate means to meet the wants of these cases, it has been an absolute impossibility to do justice in this matter. Prisons are not constructed in view of being converted into county hospitals, and almshouses are not founded as receptacles for the insane. And yet, in the face of justice and common-sense, wardens are by law compelled to receive, and the masters of almshouses not to refuse, insane and idiotic subjects in all stages of mental disease and privation. It is the Commonwealth, not its integral parts, that is accountable for most of the abuses that have lately existed and do still exist. I repeat it, it is defective legislation which perpetuates and multiplies these abuses."

To call attention to this "defective legislation" was the object of Miss Dix's Memorial. To take active steps to remedy it became the task of a notable band of co-workers, such men as Samuel G. Howe, Luther V. Bell, and Horace Mann (before mentioned), William Ellery Channing, and John G. Palfrey. Dr. Howe was the chairman of the legislative committee to which the Memorial was referred. The report of the committee fully endorsed Miss Dix's statements, urged the immediate enlargement of the State Hospital at Worcester, and pointed out the need of securing the benefits of this enlargement to those for whom it was designed, by raising the rate for private patients to a sum corresponding to that asked by private asylums. Public sentiment throughout the State had been so roused by Miss Dix's revelations that the efforts of a few politicians did not avail to prevent the passage of a bill for immediate relief, and accommodations were ordered at Worcester for two hundred additional insane persons. "Thus," says her biographer, "was ventured and won Miss Dix's first legislative victory."

I have dwelt at such length upon Miss Dix's work, not only because of its important place in the history of our subject, but because of its practical value in impressing upon us to-day the dangers of indifference and neglect, and the need of constant wise and authoritative supervision. I believe it to have been the most remarkable work ever wrought within our borders by a philanthropist; and I take a personal pleasure in recalling that Miss Dix was not only a Massachusetts woman, but the granddaughter of a Massachusetts physician,—a man notable in his day for the same indomitable energy that characterized his descendant.

We may be pardoned for noting, before we leave this topic, that the condition of the insane in Massachusetts at this time—shocking as it was—was no worse than in other States. Miss Dix's investigations in Rhode Island the following year brought to light facts equally revolting. Indeed, her work in New England was but the opening of a series of campaigns, "which," says her biographer, "involved nothing less than carrying the legislatures of Indiana, Illinois, Kentucky, Tennessee, Missouri, Mississippi, Louisiana, Alabama, South Carolina, North Carolina and Maryland, besides the establishment of two entirely new

¹ Delivered before the Middlesex South District Medical Society at its annual meeting, April 21, 1897.

asylums in the British Provinces, — one at Halifax, the other at St. John."

To-day Massachusetts is among the foremost States in the Union in her wise and thoughtful supervision of the insane class. We turn now to consider the legislation which has made her so.

In 1856 the Legislature created a Board of Commissioners to execute all the laws relative to alien passengers and State paupers. The supervisory authority of this Board was limited to State almshouse visitations, but it had large administrative powers over pauper and insane persons who were likely to become a public charge.

In 1863 a Board of State Charities was established in place of the Board of Alien Commissioners, and one of the duties especially devolved upon it by statute was the investigation and supervision of the whole system of the public and correctional institutions of the Commonwealth. In 1875 it was relieved of the oversight of the institutions for the instruction of the deaf, dumb and blind, that duty being transferred to the State Board of Education, and in 1879 the oversight of correctional institutions was transferred to the Board of Commissioners of Prisons. Since the date last mentioned, the Board has undergone two changes of name, and various statutes have been enacted restricting or extending its powers in different directions; but the net result of these changes is that the Board now, under the name of the Board of Lunacy and Charity, has essentially the same powers and duties that it had in 1879. From 1879 to 1886 the duties of the State Board of Health were combined with those of the Board of Lunacy and Charity, but the change did not yield satisfactory results, and in 1886 the Board of Health was reconstituted.

Prior to 1864, in which year the Board of State Charities began its work, all the institutions for the care of the insane, as well as all charitable and reformatory institutions, were under the immediate supervision of the Governor and Council. But the other duties devolving upon the chief magistrate of the State and his assistants were too many and too arduous to allow of adequate oversight of the public institutions; and, without disparaging the abilities or the intentions of the various governors, it may be said that the actual supervision of these institutions began in 1864 with the activities of the Board of State Charities, created by the Legislature of the preceding year.

Under the existing laws, the Board of Lunacy and Charity exercises a general supervision over the State Lunatic Hospitals, the State Almshouse, the State Farm, and the State Reform Schools. It is required at least once a year to visit all places where State paupers are supported, and ascertain from actual examination whether the laws regarding them are properly observed; to visit the State Almshouse and the Lyman School for Boys at least once a month; to visit and inspect every private asylum or receptacle for the insane at least once in every six months, and as often as once a year to visit all children maintained wholly or in part by the State, all who have been indentured or placed in charge of any person by any State institution or officer, and all minor children supported at the expense of any city or town. The Board may transfer pauper inmates from one charitable institution or lunatic hospital to another, or send them to any place where they belong; it may transfer inmates of the reform schools to the State Farm,

or return them from the farm to the schools; and, under certain conditions, may transfer inmates of other State institutions or private asylums, or the Boston Insane Hospital, to the State lunatic hospitals or to private asylums and from such hospitals to private asylums and dwellings. In the performance of these and other multifarious duties delegated to it by law, it is empowered to employ agents, and to assign their duties and compensation.

Not to enter fully into the description of the duties devolved upon the Board with reference to juvenile offenders, the care of neglected children, the oversight of infant boarding-houses, the enforcement of the bastardy laws, the supervision of paupers, and the maintenance of alien immigrants in distress, it may be said, so far as the insane are concerned, that its authority and supervision are complete. Wherever the insane are found, in private homes, in almshouses, in private asylums, in any of the State institutions and lunatic hospitals, they are the objects of the watchful care of the Board. The Board acts as a guardian to all these unfortunate children of the State; it investigates each case; endeavors to place each sufferer under the conditions which it believes to be best suited to his needs, and most likely to promote his recovery, if recovery is possible; and exercises constant vigilance to prevent improper or cruel treatment of the insane. It will be seen how much the oversight of all these matters, if faithfully done, means to these unfortunate charges, and to the welfare of the State as a whole.

The growth of the responsibilities of the Board in the oversight of the insane is indicated by the fact that the whole number of State, town and private patients in the public hospitals and asylums for the insane, including the McLean Hospital, on the 30th of September last, was 6,018. Thirty years before, the whole number was only 1,795. The aggregate to-day is almost three and a half times what it was in 1867. Last year the number of new cases, by which is meant the number of persons first admitted to any hospital, was 1,730, — almost as many as the total insane population of the institutions in 1867.

But these figures do not cover all of the insane who are under the supervision of the Board. There were last year seventy-three inmates of private asylums; 129 insane patients were boarded out in private families; and there were 865 insane persons maintained in almshouses, or boarded out in families, by the various towns and cities. Altogether, here is an insane population of about 7,000.

All private asylums are required to have a license from the Governor and Council before they can receive and care for insane patients; and when so licensed they have all the privileges that belong to any hospital, large or small. There are now twelve private asylums, with capacities varying from two to twenty-seven patients. Besides these there are 522 insane belonging to the city of Boston who are not inmates of State institutions, but are distributed among the city's institutions at the Pierce Farm, the Austin Farm, on Long Island, and at the Charlestown Almshouse.

Since 1885 the Board has had authority to place in suitable families insane patients of the quiet and chronic class. Experience has shown that convalescent cases receive the most benefit from this system. There are comparatively few patients who receive

more benefit than if they remained in a hospital. Neither the hospitals nor the Commonwealth have been very much benefited by the system, and there are obvious reasons connected with the welfare of the community at large which suggest that under the present laws the system should be extended very carefully, if at all.

Last year a special visitation was made of all insane inmates of the almshouses of the State by a physician skilled in diagnosis and in the care and treatment of the insane. The report of this special visitor, Dr. Lowell F. Wentworth, is incorporated in the report of the Board of Lunacy and Charity for the present year. It gives a detailed account of all the conditions found in the several towns; and although these conditions are not in every instance such as are in full accord with enlightened methods, to read his report in close connection with Miss Dix's report of her visit to the towns is to gain a vivid idea of the marvellous progress which has marked the last fifty years. The most serious complaints of last year's visitor relate to conditions which would hardly have been noticed fifty years ago. The visitor especially emphasizes the fact that devices for the close confinement of insane patients have almost wholly gone out of use. Only fifty-one cases were found that were subject to restraint or confinement; and in but few of these cases is mechanical restraint resorted to, and in most cases where seclusion is required it is resorted to only in emergencies and for short periods.

The chief defects of this system are negative, but they are important. The patients, as a rule, are fed, lodged and clothed with general sufficiency; but medical supervision is practically entirely lacking. There is a general failure to supply the discipline in regular habits that is regarded as so valuable at the asylums for the chronic insane; and in many cases the work which the patients actually perform is insignificant.

There were found in the almshouses 250 patients who had been removed from the hospitals by the overseers of the poor. The motive in these cases is economy. The cost to the towns of maintaining patients at the State hospitals is \$3.25 per week; while the average weekly cost of maintaining almshouse inmates is \$2.46 per capita, and in some towns, by the practice of strenuous economy, is reduced considerably below that figure. This explains the solicitude with which selectmen watch the condition of the town insane who have been committed to a State institution; and if the cases are of such a character as to warrant the expectation that they can be cared for at an almshouse, and especially if the patients are able to work, their transfer is asked for as soon as the law permits, namely, one year after commitment. One singularly unjust and deplorable working of this system is that really thrifty and worthy citizens, who have acquired a settlement in a town, if they become insane are likely to be transferred to the less favorable conditions of the almshouses; while the shiftless and worthless man, having acquired no settlement and being a pauper at large, if he becomes insane receives the better care, and is better fed and lodged, in the State institutions.

Of State institutions wholly devoted to the insane, we have at present seven.

The opening of the Worcester Insane Asylum, in 1833, has been already referred to.

The second State hospital was that at Taunton, opened in 1854; the third that at Northampton,

opened in 1858; then the Worcester Lunatic Hospital, opened in 1877, the original Worcester Hospital becoming the Worcester Insane Asylum devoted to chronic cases; then the hospital at Danvers, opened in 1878; next the Homeopathic Hospital at Westborough, opened in 1886; and last the Insane Asylum at Medfield, opened in 1896.

The Asylum Wards at Tewksbury were opened in 1866; and the Asylum Department at the State Farm, now known as the State Asylum for Insane Criminals, in 1887.

The cost of constructing and equipping these several institutions, and the number of inmates in each March 1, 1897, were as follows:

	Cost.	Inmates.
Worcester Insane Asylum	\$265,000	448
Taunton Lunatic Hospital	695,000	836
Northampton Lunatic Hospital	615,000	568
Worcester Lunatic Hospital	1,135,000	843
Danvers Lunatic Hospital	1,570,000	861
Westborough Insane Hospital	575,000	536
Medfield Insane Asylum	1,100,000	650
This asylum, when completed, which will be by the end of the year, will have about 1,000.		
The Asylum Wards at Tewksbury	38,000	496
And the Asylum Wards at the State Farm	50,000	304

Outside of Boston, no city has availed itself of the statute which permits cities with a population of more than 50,000 to establish and maintain a municipal asylum for the insane; but seven cities—Lawrence, Lowell, Lynn, Pittsfield, Salem, Springfield and Worcester—maintain separate departments for the insane at their almshouses.

Each of the State hospitals is under the supervision and control of a board of trustees appointed by the Governor and Council, who hold all the property in trust, and manage the affairs of the hospital in the same way that the directors of any corporation manage its affairs. They receive from the State treasury \$3.25 per week for the care of each patient, with the exception of the asylums at Medfield for the care of the chronic insane, where the payment for each patient is only \$2.80 per week. If the trustees can care for their patients for less than the sum paid by the State, they are at liberty to use the surplus in alterations, repairs and improvements. This they often do, diminishing by so much the appropriations which they ask from the State for such purposes.

In round numbers, the State institutions for the care of the insane have cost for construction up to the present time more than six million dollars, not including any interest account. Their total room and ward capacity, when Medfield is completed, will not be far from 5,000. The number in these hospitals, March 1st of the present year, was 5,543.

Now, if 350 of these are transferred to Medfield when it is finished, there will still remain, not making any allowance for the natural increase in numbers, nearly 200 who will have at night to occupy cots in corridors and halls that were never designed for sleeping apartments, and which during the day are used as sitting-rooms and passageways.

The method of distributing patients is simple: the State is divided into hospital districts, and the insane in each district are committed to the hospital belonging to the district, with the exception of the insane of the city of Boston not maintained in the city institutions. These are sent to whichever of the State institutions may be able to receive them, by the direction of the Board of Lunacy and Charity.

At this point I desire to say that, from many visits during the past two years to our several State hospitals, I have been, without exception, very favorably impressed with the character and earnestness of the men who have them in charge, as well as their assistants and helpers. They certainly are watchful and tender in their care of the unfortunates committed to them, and make the best possible use of the means allowed them by the State. At all the State hospitals I have found clean beds, well-aired rooms, and good food, together with proper amusements, arrangements for outdoor exercise and, as far as possible, suitable provision for the healthful employment of those who are able to do any kind of manual labor.

It seems fitting that I should close these fragmentary remarks by a reference to what is being done at the present time at the McLean and some of the State hospitals in the scientific study of the pathology and treatment of insanity.

The initiative in this important movement, as most of you know, was taken by him who addressed you one year ago. When Dr. Cowles began this work eighteen years ago, I am sure he could not have appreciated its full import or forecast its results. Any one who will read his annual reports of the asylum of the first part of these eighteen years will see that one of the constant inquiries was, What can be done in an asylum laboratory beyond the usual disappointing post-mortem investigations into the pathology of insanity? There were comparatively few asylums anywhere, and very few in this country, where even these inquiries were systematically attempted; and although in many of the better asylums the physicians had been abreast of the profession of their time in general therapeutics as applied to the treatment of the insane, and were alive to progressive measures in their care and management, it had been for half a century such a struggle against difficulties, often overwhelming, to provide them humanely with shelter and common comforts that the executives of the asylums were still largely engaged in problems of construction,—in striving for means to meet material needs, in house-keeping and farming, and organizing the details of administration. This work has brought, to the credit of the Commonwealth, in the last twenty years, a complete change in its asylums, with the three new ones, and the four old ones practically rebuilt, their capacity having been doubled and their comfort nowhere excelled in similar institutions. The remarkable transformation in the same period of twenty years that has taken place in the methods of the general hospital and in general practice is well known. It was the introduction of the hospital idea into the McLean Asylum—a name now changed to the McLean Hospital—that inspired the evolution of its clinical laboratory, which was new in the conception of the idea that laboratory investigations in the asylums for the insane should be based upon the principle that “the pathology of insanity begins before the insanity begins.” The difficulty was to combine with the treatment of insanity the results of other departments of scientific research; it was not only the problem of applying the new principles of physiological psychology to mental pathology, but to recognize, as in general medicine, the fact that mental symptoms may have relation to all the elements of vital activity, physiological and chemical.

Dr. Cowles also established a training-school for

nurses. The proper nursing of the insane has been one of the chief problems of the alienists, beginning with Pinel and Tuke; for nearly a hundred years the best of them have earnestly studied this question. Massachusetts claims the credit of solving this problem by the extension to the insane of this modern reform in nursing. Mr. Burdett, in his great work on “The Hospitals and Asylums of the World” (published in 1891), after recounting what had been done in Great Britain, writes: “We must, however, go to the United States of America to find a perfectly equipped and entirely successful training-school. To Dr. Cowles of the McLean Asylum, Massachusetts, belongs the honor of having instituted and brought to a high state of perfection the first complete training-school for attendants upon the insane.” The import of this cannot be better stated than in Mr. Burdett’s own words, which must find a cordial acceptance here. He says of Dr. Cowles’s work: “Realizing as we do the enormous importance which that work cannot fail to have in all its bearings upon the treatment of the inmates of the asylums all the world over, we feel that the nations owe him a debt of gratitude for the successful establishment of the McLean training-school, the usefulness of which will become more and more apparent as years roll by.” This prediction is beginning its fulfilment in the rapid spreading of these schools in the asylums of this and other countries. The founder of the first one foresaw that these schools are to be the first step in providing the means essential for the new method of careful scientific clinical observation.

The improved methods for clinical and pathological study introduced at the McLean Hospital—methods so new, valuable and inspiring—have been taken up by some of our State hospitals, notably those at Danvers and Worcester; and the time, I believe, is close at hand when every State institution for the care of the insane, including those at Tewksbury and Bridgewater, will have laboratories for investigation, and skilled pathologists to work in them. Besides this, I hope that we shall soon see each institution set apart a special hospital building as a reception ward where the newer patients can be kept by themselves for observation, and such special treatment as may be provided for them. Later, those that are regarded as incurable will be separated from the others, and given whatever care they may need; so that the physicians may concentrate the larger part of their energies upon the acute cases, in the hope that many of them may be permanently cured. In comparing the State hospitals with the McLean, it should be remembered that the latter is a private institution, with resources of its own, which permit it to do about what it pleases; while the State institutions are supported from the public purse, and the heads of them have to keep within their appropriations, and can make no improvements the necessity of which does not appear clear to the Legislature, which holds the purse-strings.

Concerning these newer clinical and pathological studies inaugurated at the McLean Hospital by Dr. Cowles, it may be asked what has already been accomplished in our knowledge of the pathology of insanity, and how much reason have we to expect that improved methods of treatment will follow. My answer is that good results must always follow scientific methods, and that we have a right to hope and expect that in due time the pathologists will throw

light upon forms of insanity that are now hidden mysteries, and will discover rational and effective methods of treatment for them. I do not forget that there are some alienists of good repute, and with deep interest in their professional work, who do not take so hopeful a view. I fully recognize also the difficulties that stand in the way of the solution of these problems in mental pathology; but if we remember what has been accomplished in medicine and surgery in the last quarter of a century, we may take courage, and hope that like results will follow like patient and painstaking methods in the study of mental disease.

It is too early yet to insist upon great results. It is the history of most of the great discoveries in science that a long and seemingly fruitless period of investigation is followed first by a glimmer of light, and then by one illumination after another, until some previously dark domain of unsolved mystery is flooded with light. Take the work of the great Pasteur as an example. What if he had been interrupted midway in his studies with the sharp challenge to produce some fruits of his toil? His establishment of the germ theory of disease led up to the discovery of antitoxin for diphtheria, a method of treating infectious disease which is destined to play such an important part in our future therapeutics. Pasteur spent his life in patient scientific investigations and died scarcely dreaming of the mysteries to which his partial discoveries would supply the key. Yet how rapidly one mystery after another has been unlocked as a consequence of his labors!

In the same way we may expect the study of the pathology of insanity to be fruitful. The new methods not only supply an incentive to study and discovery, but, as a consequence of closer personal attention, they insure a wiser and more humane treatment of patients. We do not need to go back as far as the time of Henry VIII and contrast his "Bedlam" with one of our modern asylums for the insane; we need only compare our institutions as they are now with what they were half a century ago, to see how great is the progress that has been made. The old, cruel forms of restraint have been done away; there is now the minimum of coercion. We have brought to bear upon diseased minds the healthful and recuperative influences of amusement, occupation, education and religion; discriminating treatment of individual cases has taken the place of the mere herding together of the insane; kindness has supplanted brute force; and the old hopelessness has yielded to intelligent and persistent remedial methods. In the near future we may hope that mental maladies will be looked upon by the community at large, not with an eye of suspicion and fear, but with the feeling that they are no more humiliating or disgraceful to those afflicted with them than a case of typhoid fever or pneumonia might be. There is ground, moreover, for the hope that fuller pathological knowledge may tend not only to the cure but even to the prevention of insanity.

THE PARIS HOSPITALS. — It is stated by the correspondent of the *Medical Press and Circular*, that the hospitals of Paris need the expenditure of at least £1,000,000 to make them habitable, and a further outlay of another £1,000,000 to make them what they really ought to be.

THE DIRECT TRANSPLANTATION OF MUSCLES IN THE TREATMENT OF PARALYTIC DEFORMITIES.

FIVE CASES OF TRANSPLANTATION OF THE SARTORIUS MUSCLE.

BY JOEL E. GOLDTHWAIT, M.D., BOSTON.

THE fact that the tendons of non-paralyzed muscles can be attached to the tendons of those which are paralyzed with a marked improvement in the usefulness of the part, as well as correcting or diminishing existing deformities, has been definitely proved. During the past three years, since careful attention has been given to the subject, quite a large number of cases have been treated by different surgeons with very generally good results. Personally, of the thirty cases which have come under my care, the improvement, with one or two exceptions, has been very decided.

Until a year and a half ago these operations had been confined entirely to the re-attachment of muscles which had distinct and well-formed tendons; but as the results in these cases were so gratifying, it was natural to try the same principles in other parts in which the mechanical conditions were similar although the anatomical structures were unlike. It was found in a large number of cases of infantile paralysis, in which the thighs were involved, that the sartorius and the tensor vaginæ femoris frequently escaped the otherwise general paralysis. The latter, because of its small size and the limited range of its contractility, is of comparatively little importance either in producing or for use in correcting deformities. The former, however, is different; naturally a long and strong muscle, with its spiral position and the fact that between its distal and proximal attachments are two large joints, it is evident that, if not properly antagonized, it can produce undesirable results. The outward rotation of the leg, together with the flinging gait so often seen in infantile paralysis, is largely the result of the action of this muscle. The ilio psoas, and some of the deep rotators, do, of course, play a part; but from the better attachment, mechanically, the sartorius is undoubtedly the most important.

Normally, when the other muscles of the thigh are present, the sartorius by its contraction causes flexion, abduction, and outward rotation of the thigh, and also, to a limited degree, extension of the knee. In its normal position, resting as it does upon the strong anterior group of thigh muscles, it (the sartorius) in the middle of the thigh is raised at least an inch from the femur, so that in its contraction the quadriceps acts as the fulcrum over which the power of the sartorius is applied. It is this position or elevation of the sartorius upon the quadriceps that makes it possible for it to act as an extensor of the knee.

When, however, the muscles are affected as they are in poliomyelitis (acute anterior), the mechanical conditions change. The quadriceps extensor, instead of being an inch or more thick, becomes so much atrophied that it is represented by a thin fascia. The sartorius, as the result of this, practically rests upon the femur; and in changing its position it not only sinks down against the bone, but is drawn farther backward on the inner side, so that as the result it crosses the femur nearer the upper part of the thigh than is normal.

In the new position, together with the absence of

the muscles which normally antagonize it, the sartorius by its contraction causes an increase in the normal amount of flexion, abduction and outward rotation of the thigh; and at the knee, instead of causing extension, it becomes a flexor. This can readily be demonstrated by having the patient sit upon a table so that the legs from the knees hang freely. Upon contraction of the sartorius, with the flexion and rotation of the thigh, which is expected, the foot and leg are drawn backward, not forward, this being the most conspicuous part of the movement.

It is obvious from this, that with the muscle so situated its presence is in part a disadvantage, and as far as the control of the knee is concerned, it would have been better had it been involved in the otherwise general paralysis.

About two years ago I described an operation at a meeting of the Boston Orthopedic Club, and later showed a patient at the Surgical Section of the Suffolk District Medical Society in Boston in which the sartorius muscle was transplanted and attached to the quadriceps extensor just above the patella. When the operation was first planned it was with the hope that by giving this muscle, which normally possesses considerable strength, a better mechanical attachment, the undesirable deformity would be corrected and the usefulness of the leg be increased.

Since that time I have operated upon five patients for this purpose. In three the result has been a marked improvement, in two the result was a disappointment, the failure probably being due to imperfect methods of attaching the muscle. With the more perfect technique and with greater experience such failures should not result.

Of the three successful cases, one, a grown woman twenty years of age, has at the present time absolutely the normal amount of extension of the leg at the knee as contrasted with an entire inability to extend the leg before the operation. When sitting she is able to straighten one leg and hold it straight (thus supporting all of the weight of the leg) quite as well as the other. Upon standing, at the present time, the patient is able to bear all the weight of the body on the lame leg, without artificial support, the sartorius being strong enough in its new position to hold the joint stiff. Before the operation, there being no power in the extensors of the thigh, no weight could be borne upon the leg unless the knee was fixed in a brace, or supported by some artificial means. The flail, flinging gait, which was the only possible method of locomotion, has been entirely corrected, the leg being extended normally when the step is taken. The patient is, of course, still somewhat lame, but the lameness is due chiefly to the weakness of the foot and ankle, the mechanical difficulty at the thigh having been almost entirely corrected. No apparatus for the thigh is now necessary, and the patient has been employed doing regular housework for the past eight months. The paralysis in this case had existed since early childhood, and previous to the operation she had been dependent upon the constant use of a cane or crutch.

In the second of the three successful cases, the result will, I think, be quite as good as in the previous case. The patient, a boy twelve years of age, was first seen in consultation with Dr. C. S. Millett of Brockton, and at that time there was complete paralysis of all the muscles below the right knee, and no power in any of the anterior thigh muscles, except

the tensor vaginae, femoris and the sartorius. On sitting with the legs hanging, extension of the leg at the knee was impossible, as was also standing without support. On walking the thigh was rotated and the leg flung along.

When last seen, about five months after the operation, extension through almost the normal limit was possible. On sitting, the leg could be straightened completely, but the muscle was not strong enough to hold it fully extended for more than a moment. There has been such a steady improvement in his condition however, that I feel sure that the sartorius will strengthen enough to give quite as useful a leg as in the former case.

The flinging gait with the rotation of the leg has been entirely corrected.

The third case, a girl eight years old, had infantile paralysis of the right leg. All of the anterior muscles of the lower leg were completely paralyzed, and the anterior thigh muscles were much weakened, although they responded somewhat to voluntary effort. There was not enough power in the quadriceps, however, to completely extend the leg when the child was sitting.

The operation was performed about one year ago, with the idea of using the sartorius to help the weakened quadriceps. The result in this case has been a very decided improvement; the gait is better and the extension of the leg is likewise improved. This in some ways was a more favorable case, and the result is not so striking as in the two just reported.

The operation as illustrated consists in making a longitudinal incision about six inches long on the inner

side of the thigh, so that the middle of the incision is opposite the top of the patella. Through this the sartorius muscle is dissected out and cut off at the extreme lower end where it is attached to the tibia (x). This is then brought forward and attached to the muscular fascia just above the patella and a little to the inner side. The attachment must be made very firmly, and to accomplish this the fascia should be split and the muscle drawn through this so that it becomes adherent to both the outer and inner surfaces. For sutures, kangaroo tendon is by far the best material; catgut is not

strong enough, and is absorbed too quickly; while silk cuts out (one failure apparently being due to this). The wound should be completely closed and the whole thigh tightly bandaged with a compress bandage, with the idea of preventing the contraction of the muscles so far as possible. Over this a plaster-of-Paris bandage or a long splint should be applied to control the motion of the knee-joint. The patient should be kept lying down for two weeks at least, all attempts at sitting or even raising on to the elbows being avoided, so as to relieve the strain upon the thighs. Gentle motion at the end of three weeks should be commenced, and the plaster entirely omitted at the end of from five to six weeks.

The course of these cases after the operation has been interesting. Theoretically, from the histological structure of the sartorius muscle, made up as it is of long, slender, parallel fibres, one would expect comparatively little increase in its normal strength or size; nevertheless, as the work has been increased, the strength of the muscle has increased also, until it has been able to do quite perfectly the work of the quadriceps that would be required in walking or standing. In one case, in four months the circumference of the thigh, measured in two positions, increased one-half of an inch. This development or increase in strength has taken place, however, more slowly than would probably be the case in muscles with the fibres arranged differently.

About the time the operation was first described, a similar operation was performed by Dr. Milliken, of New York City. This case has been reported, together with a case in which an attempt was made to transplant a portion of the deltoid. Besides this, a case operated upon recently by Dr. F. B. Harrington, and another by Dr. G. C. Dolliver, at both of which operations I was able to be present, constitute, so far as I know, all the operations of this kind which have been performed. The results are most encouraging, and the improvement, especially in the first case here reported, has far surpassed my most sanguine hopes. The failures probably would not have occurred but for the newness of the operation, and the lack of perfection of the details.

The only other attempt at the re-attachment of the muscles directly, which has been made by me personally, is a case of infantile paralysis of the leg, involving chiefly the anterior tibial muscle, and resulting in a marked valgus position of the foot.

In similar cases it has been found that in attaching the tendon of the peroneus tertius, or the tendons of the common extensor, to the anterior tibial, that the tendons were so small that as the result of the suturing and necessary handling at the time of operation sloughing frequently took place, and not only was the healing delayed but the ultimate result more or less impaired. In the endeavor to avoid this, the following operation was performed:

Through a straight incision, three inches long, made longitudinally over the middle of the anterior surface of the leg, the muscle of the common extensor was dissected out and approximated to the anterior tibial muscle, and the two attached by means of quilted sutures. The attachment was made at the lower portion of the muscle, so that a portion of the tendinous expansion was included in the sutures; by doing this, none of the contractile fibres of the muscles were impaired.

The wound was then closed tightly, and the foot and leg treated with a plaster-of-Paris bandage, the same as when the tendons have been directly attached. In this way, the danger of sloughing is eliminated, and the contraction of the common extensor muscle necessarily exerts some of its power upon the inner side of the foot through the anterior tibial tendon. In this case there has been some improvement, although not as much as I had hoped; and the operation is reported as one of interest rather than as one which is wholly perfected, or for which much is claimed.

In conclusion, it has been found in a large number of cases of infantile paralysis, in which the thighs are involved, that the sartorius and tensor vaginae femo-

ris are frequently unaffected when all of the other thigh muscles are destroyed. Without the other muscles, which assist and antagonize the sartorius in its normal action, this muscle, from its peculiar position and attachment, produces undesirable results in the use of the leg. To overcome this and to make the greatest possible use of the muscle, five cases have been operated upon by the writer and here reported, in which the sartorius was divided at its lower attachment, and re-attached to the aponeurosis of the quadriceps extensor above the patella.

The result in three of the cases has been a marked improvement, in one, almost the normal usefulness of the leg resulting. Of the two cases of failure, both were probably due to the failure of the stitches to hold, so that the desired union was not obtained.

One case is reported, in which the anterior tibial muscle and the common extensor of the toes were attached in the lower part of their muscular structure in order to correct the faulty position of the foot.

Clinical Department.

MASSACHUSETTS GENERAL HOSPITAL. CLINICAL MEETING OF THE STAFF.

J. COLLINS WARREN, M.D., SECRETARY.

REGULAR Meeting, Wednesday, April 14, 1897.
DR. C. B. PORTER in the chair.

A NEW AFFECTION.

DR. JAMES C. WHITE: In 1889 a case came under my observation here—an entirely new affection. In the same month of the same year a similar case presented itself in a clinic at Paris, and was studied and described by Darier under the title "*Psorospermose folliculaire végétante*." I called the affection "*keratosis follicularis*." Dr. Bowen made an examination of the affected tissue, and made out that it was a simple hyperkeratosis, a modification of the process of cornification consisting in heaping up of modified epidermic cells in the mouths of the follicles. The clinical appearances were very various, consisting in the beginning of small, horny papules closely resembling the keratosis of lichen pilaris of the arm. From these the process extended into larger semi-globular elevations, hard, and becoming somewhat discolored. These were all seated at the mouths of the follicles. By confluence there grew large, horny concretions here and there, one-third to one-half inch in height, and of about the same diameter. The disease at its highest point of development consisted of conical projecting horns resembling miniature cutaneous horus. In that case the whole surface of the body was largely covered, and in certain parts the process was enormously developed. The case in Paris, which I subsequently saw at the International Congress, had not advanced to this degree, but Darier and the other French observers asserted that it was a case of psorospermosis, and that the peculiar cells found in the tissues were psorosperms, or coccidia, and the name psorospermosis has remained from that time to this.

Since then other cases have been observed, but only a very few, in different parts of the world. I do not doubt it was in existence a long time before, and it is my opinion that so-called "porcupine men"

(*ichthiosis hystrix*) were cases of this disease. When I returned from Paris the first patient I saw on entering the clinic was this patient, and she presented the same affection. By one who had seen the disease it was immediately recognized by this peculiar appearance of the face. The disease has not advanced very greatly since that time. The whole forehead is occupied by a mass of horny papular growths. Behind her ear the process is much more fully developed. On other parts in the pubic region this process is still more highly developed. There is a little on the wrists. It extends down on the chest in front and in the rear about the same distance. There is a little scattered eruption on the arms and legs. The very peculiar bodies which are found in every one of these papules, large round cells, are not, it has now come to be believed, animal parasites, but are peculiarly modified epithelial cells. It is not a coccydial disease, and even Darier has given up that opinion. Although the French name remains, *keratosis follicularis* is the proper name, because it is a descriptive title and not misleading. We have a case here which is of medium grade, and my first case was this young woman's father. That does not indicate that it is a contagious disease, because this girl was less than a year old when separated from her father and never saw him afterwards, nor does it show necessarily a hereditary tendency to the affection, because it is only in one or two other instances that it has affected more than one member of a family.

POINTS IN OPERATIVE TECHNIQUE.

DR. A. T. CABOT spoke of three cases showing points in operative technique and illustrated them by diagram. The first case was one of intra-ligamentous cyst. This cyst, growing in the broad ligament, pressed down behind the uterus so as to fill the whole pelvic cavity and then projected upward into the abdomen. On coming down upon it from above, the peritoneum was split and the cyst shelled out readily over its upper part from the enveloping broad ligament. When, however, the edge of the pelvis was reached, the cyst became very adherent and the walls were extremely thin, tearing readily. As the separation of this part of the cyst was evidently going to be very difficult and accompanied by hemorrhage difficult to stop, it was decided to leave it *in situ*. The edges of the cyst were then stitched to the torn edge of the peritoneum around the edge of the pelvis, so that the cul-de-sac in the pelvis behind the uterus was lined with cyst membrane in the place of peritoneum. The appearance was the same as that of normal peritoneum and, in fact, the cells lining such a cyst are similar to those of the peritoneum, so that there seemed to be no reason why it should not act serviceably in place of the peritoneum which it had displaced. The patient made an uninterrupted recovery without fever, and left the hospital well a fortnight later.

The next case was one in which, after removing a pyosalpinx on one side, the Fallopian tube and ovary on the other side were found fixed behind the uterus close to the cervix by light adhesions. After these adhesions were separated, it was found that the Fallopian tube was pervious and the fimbriated extremity apparently uninjured. It was, however, impossible to prevent the ovary and tube from falling back into the former uncomfortable position behind the uterus whenever they were let alone. To prevent this tendency

for them to fall back into the pelvis the broad ligament close to the Fallopian tube was attached to the peritoneum at the brim of the pelvis by a single cat-gut stitch. This was quite sufficient to hold them in this new position and it seemed probable that the light adhesions that would form would hold them there long enough to allow the other organs in the pelvic cavity to assume their normal relations and fill the place in which the ovary had lain so that it could not afterwards fall in there.

The last patient was a man with a long sinus running up beside the rectum and rather behind it. This had been operated upon as a fistula, and in so doing the anal sphincter had been completely divided so that the patient had absolute incontinence of feces and was incapacitated for work. It was decided to try and separate the sinus from the rectum in such a way that the rectal sphincter could be restored. For this purpose the incision usual in the Kraske operation for the removal of the rectum was made on the right side, as the sinus lay to that side of the rectum. After dividing the bone the lower part of the long sinus was made easily accessible. An opening was found about an inch and a half or two inches up into the rectum and the bridge of tissue that was left was divided, thus throwing all of the lower part of the sinus and the rectum together. Careful dissection was then made of all the tissue involved in the sinus lying on the rectal wall until all of the parts in immediate contact with the rectum and with its sphincter had been thoroughly refreshed. This defect in the posterior rectal wall was then closed by a series of layers of buried stitches, making a very satisfactory perineum, as it were, and the sinus was brought out at the upper extremity of the Kraske incision. Careful search with a probe failed to detect the cause of this sinus, although it seems probable that it depended upon a disease of the bone somewhere near the sacro-iliac joint.

The result of this operation was the complete restoration of the sphincter and entire recovery of the continence of the bowels. The sinus is very much shortened and a good drainage provided for it.

EXOPHTHALMIC GOITRE.

DR. JAMES J. PUTNAM demonstrated eight cases of exophthalmic goitre, to show the variability of this affection in type, and to illustrate certain points in treatment. A further report will be made upon these cases at another time.

The question is much discussed at the present day, whether the symptoms of this affection are due to a toxic substance secreted by the diseased thyroid gland, or present in the circulation because the thyroid gland is diseased, or whether they are due to a disorder of the nervous system; or, finally, whether we should divide the cases, as Buschan suggests, into those of true Graves's disease, which Buschan considers to be of nervous origin, and false or secondary Graves's disease, which he considers to be due indirectly to various causes acting through the nervous system. Enlargement of the thyroid would then count as one of these latter causes.

In the opinion of the speaker, the difficulties in the way of making a classification of this sort are at present unsurmountable. It is impossible to state what constitutes true Graves's disease in terms sufficiently definite to command acceptance. Different types of

the disease obviously exist, but they shade into each other, and are not separated by sharp lines.

As regards the toxic (thyroid) theory we are not able to prove or to disprove it absolutely, but the great probability is that it is not true in the sense that the thyroid disease is the only essential factor in producing this malady. It is probable that certain peculiarities or "predisposition" on the part of the nervous system must be present, or is present in the majority of cases.

This factor of predisposition is studied to advantage by a careful comparison of the conditions obtaining in Graves's disease with those obtaining in health, or in strong emotion, which is a state of quasi-health. If this be done various points of resemblance are found, such as justify the designation of Graves's disease *from this point of view* as a "neurosis of emotion."

There is no doubt that the administration of thyroid preparations excites a condition more or less closely resembling Graves's disease, and the possibility supports itself that even in health the thyroid secretion may play a part as a nerve stimulant.

On the other hand, cases of unquestionable benefit from the use of thyroid preparations in Graves's disease are occasionally seen. It is difficult to predict beforehand which cases will be the ones to respond in this way. Perhaps, as a rule, those presenting the most marked symptoms of general nervous irritability are the most susceptible, but this cannot be asserted as an invariable rule.

Dr. Putnam's cases were used so far as possible to illustrate these statements, especially those with regard to the effect of thyroid preparations. It was also shown that many patients had been benefited considerably, especially as regards their nervous symptoms, from other kinds of treatment in the out-patient department of the hospital. A part of this improvement seemed attributable to long-continued faradism; another part, of undeterminable amount, to the moral encouragement of the treatment used, irrespective of its direct effect.

THREE CASES OF CONGENITAL HEART DISEASE.

DR. CHARLES W. TOWNSEND: These three cases shown here all have the characteristic cyanosis of congenital disturbance of the heart, due either to a malformation or to fetal endocarditis. The cyanosis is variously explained as due to insufficient oxydation of the blood, to the admixture of venous and arterial blood, or to passive congestion of the cutaneous vessels. It is possible that all these factors may exist in one case.

CASE I. Nellie M., ten and one-half years old. Family history negative. At birth, her finger-nails and lips were noticed to be blue. At the time of weaning, when fourteen months old, she became more blue, and the cyanosis has increased with age. The patient has had whooping-cough, measles and scarlet fever; has not had rheumatism. She suffers from dyspnea and palpitation on slight exertion, and occasionally from pain about the heart.

The patient is fairly developed and well nourished. Her face is dusky, the lips and finger-nails being markedly blue; the fingers are clubbed. There is no edema. An examination of the heart shows the apex beat in the fifth intercostal space in the mammary line. Cardiac dullness extends a finger's breadth to the right of the sternum, and to the left mammary line. There is a loud systolic murmur heard over the whole cardiac

area, loudest in the third left interspace. A slight thrill is to be felt and the pulmonic second sound is accentuated. The exact diagnosis of the lesion in these congenital cases is, of course, always difficult, and it is not uncommon to find several lesions associated. The signs in this case would rather indicate an open ductus arteriosus. With a weakened pulmonic second sound and the other signs as before, pulmonic stenosis or tricuspid regurgitation would be thought of.

CASE II. Mary G., twenty-three years old, born in Ireland, a waitress, and the eldest of twelve children, all living and well. Has always been blue from birth. She has had measles, and at times asthma, but never rheumatism, scarlet fever nor chorea. Slightly short of breath, and troubled at times by palpitation. These symptoms have increased in the last year although she is able to do her work as a waitress. The first catamenial period occurred at the age of twenty; she has never been regular, having had only nine periods in all, the last seven months ago.

On physical examination the patient is seen to be poorly developed, short, and shows cyanosis of face, lips and finger-nails. The apex beat is in the fifth space inside the nipple. There is no enlargement, and there are no murmurs.

CASE III. Ida C., twenty-six years old, born in Naples. Is said to have a blue brother living in Italy; four other brothers are well. The patient has been blue from birth, but has always been well, and she affirms that she is able to run fast and upstairs without getting any more out of breath than others. The catamenia began at the age of fourteen or fifteen and have generally been regular. She is married, and has had two children, the first born two years ago, the second last September. Both were still-born, the first two weeks premature, the other three weeks premature.

She is a well-developed and well-nourished woman, markedly blue, especially about the lips and finger-nails. The mucous membrane of the vagina looked almost black. The heart is not enlarged and there is generally no murmur to be heard. On one occasion a soft systolic murmur over the pulmonic area was detected. The hemoglobin was found to be 70 per cent.

To test her comparative ability to go upstairs quickly, I sent her and one of my assistants down stairs in the out-patient department with instructions to run up again as quickly as they could. The assistant's pulse went up from 90 to 124 or 34 beats, while the patient's rose only 24 beats, from 100 to 124.

The absence of cardiac murmurs in these last two cases of congenital heart disease is, of course, unusual, although Holt states they are absent in one-fifth of all cases. In 19 cases, most of which have come under my observation at the Lying-in and Children's Hospitals, five, or 26 per cent., had no murmurs. One of these cases without murmur was extremely blue, and died in seven days. The autopsy by Dr. Whitney showed an opening between the two ventricles, a much enlarged aorta and small pulmonary artery. Another case, seen in private practice, where the autopsy showed a much hypertrophied heart and large ductus arteriosus, there was no murmur heard till towards the last, when a faint systolic murmur developed.

DR. CUTLER: Was an examination of the blood made?

DR. TOWNSEND: The hemoglobin in this case was 70 per cent. I think a blood-count was not made.

She has recently had an attack of gripe, and looks paler than before.

DR. CUTLER: In the case which I had, the number of red corpuscles as well as the amount of hemoglobin was very much increased.

DR. TOWNSEND: As to the absence of murmur, I should like to speak of a case I had in private practice, where there was no murmur to be heard until towards death, in a child four or five weeks old, and then a faint systolic murmur at the apex. In that case there was a large ductus arteriosus and a good deal of cyanosis.

DR. C. B. PORTER reported the following case of

INTESTINAL OBSTRUCTION FROM BAND.

January 17, 1897. L. B. B., Jr., twenty-nine years old, cigar-maker, was brought to the accident-room by Dr. Chandler, of Medford, who kindly gave the following history of the case:

Family History. Sister died of phthisis. Father now phthisical.

Personal History. Scarlet fever, yellow fever, never typhoid. Four years ago had an attack lasting a few hours, similar to present one, the pain being in the same place. The attack was relieved by enema. Two years ago and since, more or less pain in region of right kidney and groin. Has passed sand in his urine; otherwise well until four days ago.

Present Illness. Bowels have always been regular, moving every morning. Four days ago ate a boiled dinner. About 10 p. m. an attack of pain from umbilicus to ensiform. Pain paroxysmal. Became more severe. At 3.30 A. M. sent for Dr. Chandler. Temperature normal, pulse 115. Examination of abdomen negative. Required a subcutaneous injection of morphia (gr. $\frac{1}{4}$). The next morning he was given salines, which he vomited. Retained some milk and lime-water. Was comfortable till evening, when the pain and vomiting returned. Temperature normal, pulse 100. Morphia subcutaneously (gr. $\frac{1}{4}$). Given an enema without result. Passed a fairly comfortable night. Next morning (two days ago) had more pain and vomiting. An enema gave no relief. Required several injections of morphia. Yesterday comfortable all day. Evening temperature 101°, pulse 96. Last night more pain, not relieved by three one-eighth grain tablets of morphia by mouth. At 3.30 A. M. required a one-quarter grain subcutaneous injection. Since then no pain. Seen this morning by Dr. Richardson. The examination of the abdomen has always been unsatisfactory and has never shown anything definite. Two days ago took some tea and cracked ice, and yesterday some tea and milk, which is practically all patient has taken and retained. On entrance pulse 111, of good quality, temperature 100.4°. Examination made by Dr. Porter, and case discussed by Drs. Porter, Richardson and Chandler. Decided to put patient to bed and wait for results. Nutritive enemata every four hours. Milk and lime-water, drachm doses; calomel (gr. $\frac{1}{10}$) every half-hour for six doses.

Physical examination made in the afternoon. Rather thin, fairly well-developed and nourished young man. Perfectly comfortable. Abdomen tympanitic all over; somewhat distended; umbilicus not quite flush with surface; slightly more rigidity over right iliac fossa than over left; some tenderness on deep pressure from region of spleen down to left iliac

fossa. Gurgling sounds heard by stethoscope all over abdomen. Rectum empty, ballooned out. Nothing definite made out. After the calomel, patient has felt as though he might have a movement. Passed only a little gas. No nausea. Blood: 1 P. M., whites, 14,000.

January 18th. Passed fairly comfortable night. Took milk and lime-water, without nausea. Enema this morning passed in part with some gas. Milk and lime-water increased. Patient in considerable pain. High oil enema followed in an hour by soap-suds and glycerine with two drachms turpentine and fifteen grains aloes. Had a good movement. Pain still continued. Knees drawn up. Suppository (morphia, gr. $\frac{1}{4}$) of no benefit; finally, a quarter grain subcutaneous injection. Patient began to have bile-stained vomitus. Previous to this, and after movement of bowels, had been put on to liquid diet. Seen by Dr. Porter. Enema without result. Blood: 8 A. M., whites, 12,000. Urine: albumin, trace of sugar, 1.027, acid, color +. The sediment contained abundant pus, a few large and medium-sized round cells, with fat, one granular cast of large diameter, questionable hyaline casts.

Transferred to Ward E. for operation.

Incision from a little above umbilicus on right to mid point between umbilicus and pubes. Fibres of right rectus separated. Peritoneal cavity opened. As soon as opened coils of intestine immediately forced out on to abdominal wall. Hand introduced. Presenting coils covered with warm towels. Intestines in upper part of abdomen distended, those in lower part empty. Intestines somewhat congested. Small intestine, which had forced its way through the incision and which was distended, followed down. Finally, the mark of a constriction was found about the lumen, reducing it perhaps to half its size. Further examination found a short, thick band joining two loops of the small intestine, lying in the right iliac fossa. The bowel, with the constriction, had been caught by this band, and during the systematic examination of the intestine had been pulled free of the band before the latter had been discovered. Band clamped with two hemostatics and cut between. Ends tied with braided silk and allowed to fall back into abdominal cavity. The coils of intestine lying on abdominal wall too distended to permit of reduction into abdominal cavity. Everything covered up except about six inches of gut. Small incision then made, and intestinal contents pressed out from coils above. Incision in gut closed by continuous Lembert suture and then reinforced by several interrupted ones. Area washed off with peroxide and then drenched with sterile water. Intestines could then be easily replaced. Abdominal incision closed without drainage. Dressing, swathe.

During the operation the rectal tube had been put in, and a small amount of fluid escaped, possibly the remains of an enema, which had been given only a short time before the operation.

Patient in pretty good condition. Strychnia hypodermically. Enema: black coffee, brandy, digitalis, salt solution. Seen by Dr. Porter in the late afternoon and evening. Enema every four hours. Shaved ice and brandy by mouth.

January 19th. First day after operation. This morning enema not retained, passed with much gas. Enemata omitted. During the night vomited occasionally. Diet increased gradually to milk and lime-

water. To-day somewhat distended. Has passed a great deal of gas by rectal tube, unable to pass wind unaided. As the gas accumulates causes much discomfort, which is immediately relieved by its passage. Milk and lime-water nauseates, hence oatmeal gruel.

For a number of days difficulty with gas, requiring rectal tube and enemata. Soft solids on fourth, and house diet on sixth day after operation. Except for slight infection of stitches convalescence uninterrupted, and patient discharged on the sixteenth day after operation, with abdominal support, bowels moving daily with a mild laxative; no pain.

CLEFT PALATE.

DR. C. B. PORTER also presented a number of operations for cleft palate.

CASE I. This young man had cleft palate and had also been operated upon for hare-lip, the result of which certainly was not as good as that following my operation. The cleft in the palate is closed completely and he has had a bridge made in front to fill up the hiatus of the teeth gone so that it makes a most presentable lip and mouth. He is twenty. I did the first operation eighteen months ago.

CASE II. This young man is now undergoing some elocutionary gymnastics and his speech will undoubtedly improve a good deal though it is now much better than before operation. He has only been operated a few months, and the day after he was operated he developed diphtheria together with my assistant who was present at the operation, and that delayed his recovery, although the palate has united entirely. He is twenty-two.

CASE III. I operated on this patient five years ago. This case is really very successful indeed. I think if he had the small hiatus in front filled with teeth like Case I he would get rid of the slight whistle heard at times as he can carry his palate close back against the posterior wall of the pharynx. It seems to me when he gets this little fissure closed he will speak perfectly plain.

I would like to say a few words in regard to the operation, and that is that the angle made by the two halves of the hard palate is usually very acute. Instead of having an arch the two sides come in at an angle and when the soft parts are dissected off from the hard palate it is difficult to pass the sutures in the anterior part of the fissure and in the last two operations I have cut the soft parts free in front so that the two flaps hang down into the month, then the sutures are placed with ease. I use silk sutures soaked in compound tincture of benzoin, which prevents them from slipping when tied. I also insist on an obturator like a plate for artificial teeth, to protect the wound from pressure of the tongue in swallowing, that means that I never operate unless there are teeth enough to which to fasten the obturator. I operate under ether and in the Rose position.

ATONIC DILATATION OF STOMACH: GASTRORRHAPHY.

DR. F. C. SHATTUCK: The patient, a Gloucester fisherman, forty-seven years old, entered the Massachusetts General Hospital, January 18, 1897.

Brother died of heart disease.

Had used no alcohol or tobacco. Denied venereal disease. Had usual children's diseases, measles at twenty-four, "slow fever" at nineteen, for three months, no cough.

The present illness began in 1883. Had, about once a year, periods of vomiting, with nausea and inability to retain food on stomach. These lasted for a week to two months, and kept him from work. Attack preceded several days by gastric distress and water-brash. Would usually lose twenty to fifty pounds, which was quickly regained after stomach symptoms subsided. Each attack was worse than the one preceding, both in severity and duration.

For the last five years the attacks have come twice a year and usually last a month. A year ago he was ill three months, and lost forty pounds in weight, which he regained in the next two months. After this his health was very good until last May, when the old trouble again returned. Since then he has vomited daily, and pain and distress in stomach have increased.

Ten weeks ago, while out in a fishing schooner, the vomitus for a fortnight was like coffee grounds. From that time he has done practically no work, but has not been confined to bed. Recently, as a rule, he is comfortable during the day, but toward evening is taken with a gnawing pain in the epigastrium which gradually increases until he vomits in the middle of the night. The pain gradually wears away.

Vomitus varies in quantity from a pint to a gallon, yellow or dark colored, very sour smelling, often containing undigested food.

Patient has marked constipation: he may have no movement for a week. The dejections are occasionally black and tarry, usually not.

There are eructations of gas and acids. Borborygmus. Appetite is fairly good.

His best weight was 200 pounds; he now weighs 148 pounds.

Physical Examination. Large skeleton; cheek-bones prominent. Tongue pale, flabby, heavily coated. Pulse strong, voluminous and forcible. Lungs negative. Heart: small area of dulness; no murmurs. Liver: fifth rib, no edge felt. Inguinal glands of good size. Epitrochlear glands enlarged. Knee-jerks active. Urine: normal color, alkaline, 1.018½, no sugar, no albumin, no diazo, sediment heavy, amorphous phosphates. Blood: reds, 3,536,000; whites, 9,400; hemoglobin, 48 per cent.

Diet: Liquids and soft solids.

January 19th. This evening vomited 37 ounces of yellow fluid. Vomitus contained hydrochloric acid. Digestion leucocytosis present. At 1 P. M., proteid meal: whites, 9,550; at 4.30 P. M., whites, 12,800; gain of 3,250.

January 20th. House diet with care. Liquids limited to one pint daily. Stomach washed after test-meal. Capacity, 3,000 c. c. Hydrochloric and lactic acids present, the latter in small amount. When inflated, lower border nearly reaches to pubes. No tumor to be felt. Daily washing of stomach before breakfast showed average residue of 15 ounces.

February 3d. Owing to dilatation of stomach, presence of hydrochloric acid, absence of tumor, and variations in weight, a diagnosis was made of atonic dilatation of the stomach; and after consultation with Dr. Porter the operation of gastrorrhaphy was advised, the patient to return if operation was decided upon.

Patient entered the Surgical Ward for operation on February 15, 1897. Examined again by Dr. Shattuck. Stomach washed out. Dilatation same as before.

February 18th. Stomach washed out in morning.

Washings clear; slight greenish tinge; vomitus contained hydrochloric acid, no lactic acid. Transferred to Ward E, for

OPERATION BY DR. PORTER.

Incision along border of ribs on left side, which reached from middle line just below ensiform cartilage to angle of ribs. Peritoneal cavity opened. Hand was introduced, and stomach found immediately below incision. Pylorus palpated, and a thickened mass felt in connection with it. Stomach pulled up to the incision. Some adhesions about pylorus and some about cardiac end made this very difficult. The stomach wall very slippery — scarcely to be held ex-

FIG. 1. — Dilated stomach, showing line of fold; *a* to be sutured to *a* and *b* to *b* with intermediate sutures.

cept with gauze — owing to the violent muscular contractions induced by the manipulation. When the stomach was at last delivered through the incision, more careful examination showed that the mass before felt was apparently behind the pylorus, and not a thickening or growth in its walls. Few enlarged glands found. One, size of large bean, removed from the omentum. Was examined immediately by Dr. Whitney and pronounced non-malignant, simply hyperplastic.

As there was some doubt about the mass near the pylorus, an incision was made through anterior wall of stomach, which was somewhat thickened. Index finger was introduced easily through pylorus, the mass lying behind and not connected with it. The incision in stomach was closed by two rows of catgut sutures through the mucous and muscular walls, a third row of Lembert silk sutures in the peritoneum; surface washed off with sterile water, and the gauzes which had been placed about this part of the stomach before the incision changed. The cardiac end of stomach was next pulled down as much as possible and one or two Lembert sutures placed in such a way that when drawn tight a part of the wall would be folded in. This was accomplished by making the space between the places where the suture passed into the wall of the stomach as wide as possible. A few similar

sutures were then placed about the middle of the greater curvature. The pyloric end of the stomach was then pulled up as far as possible and the same sutures passed. These were to be used as guides, and were so placed that when tied they would bring the line of the greater curvature as high up towards the lesser curvature as possible — perhaps one and one-half to two inches below it. These guide sutures were then tied, and the fold thus made was held invaginated while its edges were caught all the way along by a row of interrupted Lembert sutures. Holding the stomach during the last part of the operation was extremely difficult, as its muscular action seemed to have been excited by the manipulations. After the suturing, stomach allowed to retract into the abdominal cavity. No bleeding. Abdominal incision closed. Dressing, swathe. In good condition.

As soon as in bed, an enema of coffee and brandy,

FIG. 2. — Completed operation.

each two ounces. Salt one pint. During afternoon, a subcutaneous injection of strychnia (grain $\frac{1}{4}$). Patient to have absolutely nothing by mouth, nutritive enema every six hours. Beef-juice; peptonized milk, two ounces; egg albumin, one ounce; whiskey and salt solution, each one-half ounce. Soap and glycerine enema every forenoon to clean out rectum.

February 19th. Morphia (grain $\frac{1}{4}$) by subcutaneous injection last night. Patient fairly comfortable to-day. No vomiting; little pain.

February 20th. Second day. Complains of feeling nervous. Has had no vomiting since operation, not even during recovery from ether. Spits up a little to-day. Morphia (grain $\frac{1}{4}$) subcutaneously, and 30 grains of bromide in 9 p. m. enema. Seen by Dr. Porter in the evening. As patient seems to have lost ground a little, decided to start with mouth feeding. Half-drachm doses every one-half hour of albumin and water, beef-juice, whiskey, soda water, black coffee. Nutritive enemata every three hours.

February 21st. Took nourishment well during night. Nauseated but slightly on two occasions. This morning doses increased to one drachm every half hour. Enemata continued, with laudanum, five grains.

February 22d. No nausea. This morning, at 9 A. M., enema not retained, interval increased to six hours.

February 23d. During the night feeding gradually increased, so that this morning he is getting two ounces of liquids every hour.

February 24th. For a short time has been raising yellow and extremely foul-smelling sputum. Seen to-day by Dr. Shattuck, who finds trouble in bases of both lungs behind. Dulness and whispered bronchophony. One ounce of whiskey every three hours. Abdominal wound looks all right. Codeia (grain $\frac{1}{2}$) every four hours p. r. n. for cough.

February 26th. Nine days after operation. Says he feels much better to-day. Expectoration about the only thing of which he complains. Scrambled

perhaps forty-five years of age. In the anterior abdominal wall a recently healed wound, with suture marks, about 14 cm. long, extending from a point $1\frac{1}{2}$ cm. below and from a point $1\frac{1}{2}$ cm. to right of ensiform cartilage toward the left, running parallel to, and one or two centimetres below, costal margin.

No rigor. No scars or pains. Subcutaneous fat small in amount.

Abdominal wound apparently completely healed. Some adhesions of omentum in neighborhood. Peritoneal cavity free from fluid. Intestines, especially colon in its upper portions, widely distended with gas. Serosa of intestine smooth and shining. No injection.

FIG. 3. — Vertical section of dilated stomach.

eggs and scraped beef added to diet list. Liquid increased to three ounces every hour.

February 28th. Eleven days after operation. Examined by Dr. Shattuck, who finds bronchial breathing in bases of both backs, more marked on right than left. Raw oysters and gruels added to diet list. Sputum has become dark colored, and rusty.

March 1st. Temperature subnormal in A. M., quite high in P. M. Whiskey increased to one and one-half ounces every three hours. Dip toast, rice boiled, thin Irish moss blanc mange added to list, according to patient's taste. Blood: whites, 14,100.

March 3d. Sputum decreasing somewhat in amount. Still rusty. Dr. Shattuck finds that consolidation is unchanged. Whiskey increased. Some distinctly bloody expectoration. Blood: whites, 4 P. M., 23,900.

March 4th. Temperature going up. For some days evident that pulse is steadily rising. To-day probable that patient will die. One-half grain morphia every four hours to keep patient comfortable. In the evening oxygen and increased stimulation. Gradually failing.

March 5th. Fifteen days after operation. Died at 10.40 this morning.

AUTOPSY BY DR. JAMES H. WRIGHT.

The body is that of a tall, slenderly built man of

FIG. 4. — Vertical section of stomach after operation showing in-folded wall.

Stomach adherent to liver and to diaphragm by a thin fibrinous exudate. The lesser peritoneal cavity not obliterated.

Liver adherent to diaphragm by fibrinous-like strings. In the neighborhood of gall-bladder old adhesions with colon.

In anterior wall of stomach there is a row of sutures along the long axis of the organ 13 cm. long. Near pylorus a second row of sutures about 3 cm. long. No evidence of suppuration. No escape of gas or fluid on pressure.

In both thoracic cavities a very small amount of fluid containing yellowish shreds.

Left Lung. Superior lobe extremely pale. On section, contains a moderate amount of a frothy, slightly reddish fluid. Inferior lobe largely collapsed. Its inferior portion, over an area corresponding perhaps to one-fourth of the lobe, near pleura, is broken down into dirty, grayish, stinking diffuent material, rather sharply marked out from lung tissue in neighborhood. The pleura of the inferior lobe and of the posterior inferior portion of the superior lobe covered with a fibrinous exudate which in places is yellow, several millimetres thick, elastic and infiltrated with fluid. The pleura in these situations firmly adherent to visceral pleura, on which a similar exudation is present, most marked over the diaphragm, apparently opposite

to the gangrenous area of the lower lobe. Just beneath the parietal pleura near the junction of the lower ribs with the spinal column there is a half-dollar-sized flattened elevation with circular outline covered with fibrinous exudate and on section composed of a red-black material resembling clotted blood. There was no perforation of diaphragm. The fibrinous exudate of pleura in places on the lung shows numerous minute vessels extending into it from the pleura.

Right Lung. In superior lobe a chestnut-sized area just beneath the pleura in which the lung tissue is broken down into a brownish-gray diffuent stinking material rather sharply marked out from surrounding lung tissue. In inferior lobe on pleura are two circular areas covered with a dirty, yellowish-gray exudate, rather sharply defined and varying in size from a half-dollar to a dollar. These circular areas seem to correspond to similar circular yellow elevations beneath parietal pleura, which on section are made up of a dirty gray diffuent purulent-looking necrotic material. They are situated in the posterior portion of the thoracic wall. A rib passing beneath one of them was excised and gave no evidence of suppuration in the intercostal or osseous tissue beneath. The areas in the pleura correspond to extensive areas of lung tissue transformed into a brownish-gray stinking diffuent gangrenous material. The areas are sharply marked off from surrounding lung tissue. The inferior lobe is markedly collapsed; its pleura and the pleura of the posterior and inferior portions of the upper lobe covered with a fibrinous exudate which in places is yellow, thick and infiltrated with fluid. The tissue of the superior and middle lobes is extremely pale, not consolidated and contains a small amount of fluid. In lower lobe there is apparently some consolidation in the neighborhood of one of these gangrenous areas, the tissue being resistant, grayish and homogeneous. The pulmonary arteries leading to the inferior lobes of both lungs were dissected, but no good evidence of embolism could be made out. Bronchi injected, and contain a considerable amount of a dirty grayish opaque fluid.

Stomach. The long row of sutures corresponds to the infolding of the stomach wall, the short row to a wound in the stomach wall with inversion of the edges and coaptation of the sound edges. At the pylorus there is a distinct loss of substance in the mucous membrane in the form of an oval ulcer, five centimetres long by two centimetres wide and perhaps four or five millimetres deep. Its margins smooth, to a considerable extent undermined and the mucosa projecting over. The floor fairly smooth with three to four small polypoid projections. The edge of the ulcer reaches to within one or two millimetres of the pylorus. The tissue in the neighborhood of the ulcer not especially indurated nor is the stomach wall especially thickened about it. The pylorus admits the index finger. The stomach, as it appears with the pleat in its wall, is of moderately large dimensions. The stomach contents show no evidence of hemorrhage. The mucosa not remarkable. Other organs not remarkable.

Anatomical Diagnosis. Ulcus ventriculi, with dilatation of stomach; gastrorrhaphy; gastrotomy; circumscribed fibrinous peritonitis; gangrene of lungs; fibrinous pleuritis.

Bacteriological report. Cultures in blood serum; spleen, liver, kidneys, and left side of the diaphragm

sterile; heart: one medium-sized, round, whitish, shining colony made up of staphylococcus pyogenes albus. Right pleura: Four colonies of staphylococcus pyogenes albus, and one of staphylococcus pyogenes aureus. Gangrene of lung: A fairly large number of colonies of staphylococcus pyogenes aureus; also numerous small, round, moist, colonies made up of streptococci.

DR. SHATTUCK: It seems peculiarly hard that this patient above all others should have succumbed to deglutition pneumonia because his stomach was washed out the morning before operation.

DR. WRIGHT: The autopsy showed that the cause of death was gangrene of the lungs. The stomach itself presented the greatest interest. I have here the specimen, hardened in formaline. This is the anterior aspect of the stomach wall. Here is the esophagus; here is the pyloric end. Along here you see a row of sutures, and at this point another row of sutures near the pylorus. When we open the stomach we find that the long row of sutures corresponds to an invagination of the stomach wall along this line, and at the pyloric end of the stomach we see a round ulcer about the size of a quarter-dollar, with smooth margins, a rather indurated base, and no extensive thickening of the stomach wall; in other words, a simple ulcer of the stomach situated exactly on the margin of the pylorus. At the autopsy I could find no evidence of stricture of the organ, but it seemed to me very probable that this ulcer might have interfered very materially with the working of the pylorus. The bacteriological examination of the various organs showed infection which proceeded from the lungs.

TWO CASES OF AORTIC REGURGITATION AND TABES DORSALIS.

DR. H. F. VICKERY: I desire to show two patients who came to me in the Out-Patient Department. The first one who appeared was the father of the second one. Two years ago, at the age of thirty-six, he complained of some stomach trouble. Incidentally, in examining him, it was noticed that there were enlarged glands in the neck and at the elbows, and that the pulse was of high tension, with the aortic second sound sharp and accentuated, without any cardiac murmur. He now presents the well-marked symptoms of an aortic regurgitation and of tabes dorsalis. With regard to the origin of the trouble, we have no history of any primary lesion. He acknowledges venereal exposure.

The little girl, who is now approaching fourteen years, is perhaps rather small for her age. She was the result of the first pregnancy; and since then two children have been still-born very near term. She was brought for a choreiform condition; she was nervous and fussy, and would drop things. She has improved a good deal. Other things to be noticed about her are as follows: around the angles of the mouth there is a scar-like condition; as her profile is seen, the bridge of the nose shows an abnormal depression, the frontal bone is large and the frontal eminences are well-marked; the upper central incisors are distinctly peg-shaped; there is evidence of a former keratitis.

All these things exist without a history of primary or secondary lesions in the family. As is often the case, the importance of the late manifestations are

entirely disproportionate to what seems to be the importance of original lesion.

DR. F. C. SHATTUCK reported briefly cases of

ACUTE CEREBRO-SPINAL MENINGITIS,

and showed one or two patients from the wards.

DR. WRIGHT: Cerebro-spinal meningitis is a disease characterized by a purulent infiltration of the meninges of the brain and cord. The pneumococcus and various other organisms have been found associated with this condition. It has long been believed that the pneumococcus was the most common cause of all forms of cerebro-spinal meningitis and of purulent lepto-meningitis. In 1887 Weichselbaum, and later others, called attention to a certain organism in certain epidemic cases. These observations were confirmed in 1895 by Jaeger, who maintained that this organism is the cause of the epidemic form of the disease. This idea I do not think is altogether borne out by the facts, but it seems very probable that a large proportion of cases of the epidemic form of this disease are due to the infection by this organism of Weichselbaum.

The present epidemic is apparently due to infection with Weichselbaum's coccus. The organism has no special difference from other cocci in its morphology. It is found inside the pus cells of the exudate and the appearances on direct microscopical examination of the exudate reminds one of the gonorrheal pus as seen under the microscope. In cultural peculiarities this organism differentiates itself from the gonococcus by the fact that it grows on ordinary culture media. It is entirely different from the ordinary pyogenic cocci. In some cases it grows readily, in other cases it is difficult to cultivate. In our autopsies here the exudate was very slight in amount and the microscopical examination showed extremely small numbers of this diplococcus in the pus cells. In one case the microscopical examination of the brain showed infiltration of the cortex with leucocytes in addition to extensive infiltration of the meshes of the pia. The cultures from both cases gave unsatisfactory results. Anatomically these two cases were remarkable by reason of the small amount of exudate on the surface of the meninges, by the coincidence of pericarditis in one and of areas of softening in the frontal lobes in the other. There was an endocarditis in the other case.

The experience of other pathologists in Boston who have made cultures from these cases is very much like ours here. They have found the organism extremely difficult to cultivate from the autopsy. From spinal punctures, however, for some reason or other the attempts have been more successful and I saw not long ago a spinal puncture in which there was an enormous amount of leucocytes present and many of them filled with this organism. From the fluid thus obtained Dr. Wentworth obtained numerous colonies of the characteristic organism. It is rather difficult to explain this negative result of autopsy culture. It may be explained by the fact that the organism has a certain slight vitality in the tissues, causes the trouble and dies out much in the same way that the gonococcus infects the Fallopian tubes, causes suppuration and dies out and the tubes are found sterile.

DR. TOWNSEND: In one case that occurred in my private practice the inversion of the thermic curve was very well marked for several days, the temperature being normal at night and 103° to 105° in the morning. In another case I saw in consultation the tem-

perature remained normal nearly all the time. The patient was a small child, had frequent convulsions and retraction of the neck, but at no time apparently was the temperature elevated.

INTERMITTENT HYDRONEPHROSIS.

DR. MAURICE H. RICHARDSON showed a patient upon whom he had operated for intermittent hydronephrosis. The cause of the dilatation of the renal pelvis was an obliquely inserted ureter. The principle followed was that of the Heinecke-Mikulicz operation for stricture of the pylorus. Fenger had adapted this principle to strictures of the ureter and to him Dr. Richardson was indebted for the suggestion of this method for the relief of an obliquely inserted ureter.

The patient, a nurse of twenty-eight, had had intermittent pain in the region of the gall-bladder. Exploration showed a tumor of the kidney, evidently a hydronephrosis. Further observation proved this to be intermittent. It was determined to explore, and if possible to remedy the obstruction. The kidney was exposed, and the ureter found so attached that dilatation of the renal pelvis compressed the ureter. The insertion of the ureter was altered and its calibre enlarged by first making a longitudinal cut through both pelvis and ureter, and by then closing the cut transversely.

The patient made a complete recovery, and was exhibited in perfect health.

Recent Literature.

Hysteria and Certain Allied Conditions. By GEORGE J. PRESTON, M.D. Small 8vo; pp. 298, with three plates and thirteen illustrations. Philadelphia: P. Blakiston, Son & Co. 1897.

It is somewhat singular that, with the exception of chapters in the recent systems of medicine, which sometimes have almost attained the dignity of monographs, we should have in English no work upon hysteria which embodies the modern investigations upon this disease. Dr. Preston's work, giving, as it does, a clear and concise summary of the recent French treatises, is therefore a welcome and useful publication. Dr. Preston has not only made a careful study of such recent treatises as those of Pitres, Gilles de la Tourette and Richer, but he has also made a survey of the earlier literature, so that he gives an interesting sketch of the earlier theories as to the nature of the affection. In two hundred and twenty pages he gives a history of the disease and the essential facts in regard to symptomatology and diagnosis. To do this in so limited a space is something of an achievement, and he has contented himself in the main with giving a synopsis of the recent French work with only an occasional addition from his own personal experience. In this we note two rather serious omissions. In the chapter on etiology he scarcely speaks of the importance of trauma in producing hysteria, although occasional reference to it is made elsewhere in the book. He says nothing, furthermore, as to the theories of Janet as to the psychical nature of the various symptoms of the disease, theories, which, although somewhat abstruse, are nevertheless of importance in explaining the anomalous character of certain symptoms and in prov-

ing that many supposedly feigned symptoms, such as unilateral amblyopia, may be real. Like the majority of the French authors, too, Dr. Preston in his chapter on diagnosis does not commit himself definitely upon the question whether contracted visual fields, hemianesthesia, and like stigmata can be accepted as definite proof of hysteria, and he makes only a brief allusion to the importance of the differential diagnosis between hysteria and multiple sclerosis, quite neglecting the English work upon this point. We look in vain in this, as in most of the French treatises, for any definite statements as to the prognosis of hysteria. Such omissions, however, may be accounted for by the necessity of condensing the material into so limited a space and by too exclusive dependence on French models, and they can readily be corrected in a future edition. The chapters on treatment, which take up the last seventy-five pages of the book, are based more upon personal experience and are excellent. The author is no follower of new fads, but his advice is clear, concise, and full of good judgment, and the various fashionable panaceas which have arisen from time to time for the treatment of hysteria receive their just deserts. The book is a very useful manual for all who wish to have in English a summary of our present knowledge of hysteria.

Water and Public Health. By JAMES H. FUERTES, C.E. Pp. 75. New York: John Wiley & Sons. 1897.

Water-Supply, considered principally from a Sanitary Standpoint. By PROF. WILLIAM P. MASON. Pp. 504. New York: John Wiley & Sons. 1897.

Water and its Purification. By SAMUEL RIDEAL, D.Sc. (Lond.). Pp. 292. London: Crosby Lockwood & Son. 1897.

The work prepared by Engineer Fuertes consists mainly of a comparative study of the mortality statistics of different cities with reference to their public water-supplies, typhoid fever being taken as the principal sanitary index of the purity of such supplies. The work is fully illustrated with very clear and well-executed diagrams and tables, together with appendices giving the death-rates from typhoid fever in different cities during the six years 1890-95, brief descriptions of the sources of supply in different places, etc.

The character of Professor Mason's excellent work is indicated by the following titles of subjects treated in the different chapters of the book: Introductory, containing a valuable historical sketch of the subject; Drinking-water and Disease; Artificial Purification of Water; Natural Purification of Water; Rain, Ice and Snow; River Water; Stored Water; Ground Water; Deep-seated Water; Chemical Examination of Water; Bacteriological Examination; Quantity per Capita; Action upon Metals. The volume is fully illustrated with maps, cuts and diagrams, including a copy of the normal chlorine map of the State Board of Health of Massachusetts. The book will prove valuable to all physicians, engineers and chemists, and all others who are studying the important problem of water-supply.

Mr. Rideal's work treats the subject in a similar manner with that pursued by Professor Mason, with the addition of a valuable chapter on the Softening of Water, which will prove especially useful to those who live in limestone districts. The style is clear and simple, and the book is well illustrated. It is, how-

ever, surprising to find in a modern work of this character some countenance given to the old superstition of the divining-rod, in the following statement on page 75: "It is perfectly possible that a rod in the hands of a specially sensitive individual may move under the 'indication' of running water."

The success of this utterly empirical and unscientific practice, which is still resorted to in the rural districts of Great Britain and to a less extent in America, for the discovery of water, is due to the almost universal distribution of water beneath the earth's surface and the consequent ease of finding it. Just as the arrant quack usually meets with success because the majority of all cases of illness recover under any form of treatment, whether rational or irrational.

Compressed-Air Illness; or, So-called Caisson Disease.

By E. H. SNELL, M.D., B.Sc. (Lond.). Pp. 251. London: H. K. Lewis. 1896.

In this book the author treats the subject of illness due to compressed air mainly from a clinical standpoint and in consequence of his large experience as a medical officer employed by the authorities who were empowered to build the Blackwall Tunnel under the Thames. Among the chief factors which influence the incidence of this form of illness are —

(1) The pressure itself, and in general terms it may be stated that the severity of the symptoms corresponds with the degree of air-pressure.

(2) The length of stay in the compressed air.

(3) Ventilation. The author believes that thorough ventilation of caissons should be practised, and presents tables which show that the frequency of illness bears a direct relation to the insufficiency of the air-supply.

(4) Prominence is given to the practice of decompression, with the view of preventing the workmen from emerging too suddenly from an atmosphere of forty or fifty pounds' pressure to one of only fifteen. A graduated series of air-locks is employed for this purpose.

(5) Personal idiosyncracies. Young men endure the hardships due to compressed air better than old men; moderately lean men better than stout men; and temperate men better than heavy drinkers.

The symptoms have been multifarious, and include pains in limbs, paralysis, anesthesia, hyperesthesia, auditory vertigo and other serious aural symptoms.

The author concludes with a chapter on the Preventive and Curative Treatment, and adds a full bibliography of the subject.

About twenty years since, Dr. R. T. Davis, of Fall River, presented a valuable paper on this subject at a Counsellors' meeting of the Massachusetts Medical Society.

A System of Medicine. By Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D., LL.D., etc. Regius Professor of Physic in the University of Cambridge. Vol. II. New York: The Macmillan Company. 1897.

The second volume of this System of Medicine treats of Infective Diseases of Chronic Course; Diseases of Uncertain Bacteriology — (a) not endemic, (b) topical or endemic; Infective Diseases Communicable from Animals to Man — (a) of certain bacteriology, (b) of uncertain bacteriology; Diseases due to Protozoa — Intoxications; Internal Parasites. Ad-

denda — Sero-diagnosis of Typhoid Fever; Supplement to article Plague. Addendum to Yellow Fever.

The issue of this volume has been delayed for several months on account of the late appearance of the Report of the Royal Commission on Vaccination. The three sections on Vaccination take cognizance of this report. The delay has also permitted a reference in the Addenda to the Sero-Diagnosis of Typhoid Fever, by Delépine; to Yersin's Serum-Therapeutics for Plague; and to Sanarelli's Bacillus of Yellow Fever.

The statement on the title-page, "By many Writers," is amply justified by this volume, there being no less than thirty-one contributors. The important subject of Vaccinia is dealt with in three separate articles: one by Dr. T. D. Acland, one by Dr. Monckton Copeman, and one by Mr. Ernest Hart — all very competent authorities. Malarial Fever is dealt with by Dr. William Osler, and Amebic Dysentery by Dr. Henri A. Lafleur. The other contributors are equally well known and equally well selected. In further support of this statement, we may mention that the article on Tuberculosis is by Dr. Sidney Martin, and that on the Climate and the Fevers of India by Sir Joseph Fayrer.

There are seventy-seven illustrations, well chosen and well executed, and half-a-dozen charts. We recommend this volume to the thoughtful medical man.

A Clinical, Pathological and Experimental Study of Fracture of the Lower End of the Radius, with Displacement of the Carpal Fragment toward the Flexor Surface of the Wrist. By JOHN B. ROBERTS, A.M., M.D., Professor of Anatomy and Surgery in the Philadelphia Polyclinic, etc. Seventy-six pages and thirty-three illustrations. Philadelphia: P. Blakiston, Son & Co. 1897.

This interesting brochure is a contribution to the subject of special fractures, and has been written by the author after an extended investigation. He has classified the subject into a study of Cases and Specimens, Experimental Observations, Causes and Mechanism, Symptoms, Diagnosis and Treatment. The lesion is described at length, and its nature accurately shown by the accompanying illustrations taken from bony specimens, clinical cases and skiagraphic prints. The book is of value and interest, especially to surgeons liable to be called upon to treat injuries to the wrist.

Incompatibilities in Prescriptions. For Students in Pharmacy and Medicine and Practising Pharmacists and Physicians. By EDELL A. RUDDIMAN, Ph.M., M.D., Adjunct Professor of Pharmacy and Materia Medica in Vanderbilt University. New York: John Wiley & Sons. 1897.

This work contains much useful information for the readers to whom it is addressed and presents in a convenient form the reasons why certain substances are incompatible. It will have its widest use among pharmacists and students of pharmacy; but to physicians also, especially those who have some familiarity with chemistry, it will be of service in the composition of prescriptions and will likewise be of use in other ways. An indication of the solubility of substances in water or alcohol would add to the value of the book or at least some general rules in regard to this question, such as the solubility of gums in water and their insolubility in alcohol, the insolubility of resins in water and their solubility in alcohol.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 11, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

A DEPARTMENT OF PUBLIC HEALTH.

THE JOURNAL has more than once expressed the opinion that no very good prospect existed for legislation at Washington upon the subject of a department of public health until the medical profession and the various State sanitary authorities came to some agreement upon the broad outlines of a plan for that purpose.

This desirable result seems now to have been accomplished. The American Medical Association, at the Philadelphia meeting of this year, adopted a draft for a bill to establish a department of public health, and the American Public Health Association, at its recent meeting in the same city, voted to accept the measure and to do all it could to secure the passage of the bill by Congress.

It is significant that the President of the Public Health Association for this year was Dr. Horlbeck, of South Carolina, who brought all his native eloquence and his large experience as quarantine officer of Charleston to the hearty support of the proposed legislation. Whatever questions South Carolina may have had as to the general doctrine of State rights, she evidently is too wise to now revive them in the presence of a pestilence that knows no State boundaries and has not yet been compelled to recognize the frontiers of the country.

The proposed bill embodies almost all the provisions which experience in this and other countries has shown to be necessary.

The attempt to make the head of the department a member of the cabinet has been abandoned, and the commissioner of public health is to be appointed by the President for a period of six years, with a salary of \$6,000. He is to have suitable assistants and authority to employ such scientific experts as may be necessary for sanitary investigations. The various powers and duties of the Marine-Hospital Service are to be transferred to the new department, which will henceforth be charged with the supervision of national

and interstate quarantine, and the preparation of the necessary rules.

The friction which has always existed between the general government and the States upon the matter of quarantine would be much diminished, if not wholly removed, by the creation of an advisory council consisting of one member of each State board of health. This council would meet in Washington at least once in each year, and oftener if the President so directed, for the purpose of advising with the head of the department upon the question of quarantine and other matters requiring the co-operation of the States.

Provision is also made for the much needed vital statistics relating to communicable diseases, a branch of sanitary administration not even in existence for the country as a whole, though a few cities and towns and fewer States have done some creditable work in this direction.

Such, in brief, is the new bill. To a citizen of Massachusetts it seems absurd that there should be any doubt about the passage of this measure by Congress, for about everything which is required in the proposed law has been done in this State for more than a quarter of a century. The subjects of the inquiries and experiments of her board of health have been so extensive as to reach beyond the bounds of the country itself, and she may now justly demand that the United States should do a share at least of the work which every other civilized government in the world is attempting. The latest contribution to the knowledge of yellow fever does not, it should be remembered, come from our own country, which has suffered so severely from this preventable pestilence. There is no lack here of those skilled in the investigation of the communicable diseases, and it is not to the credit of our government that this skill should not be applied to the diseases of man as well as to the diseases of animals.

Whatever health bill is prepared, even by a body of competent experts, will, of course, be much changed in the course of legislation; and, if the main features of this latest attempt at sanitary legislation are adopted, we shall feel that a pestilence has, once again, as in 1879, been the awful teacher of a foolish generation, though we may well hope that the lesson will not be so soon forgotten as it was when the National Board of Health was done to death in the house of those who should have been its friends.

MEDDLESOME MIDWIFERY.

THE obstetricians of a former generation were very chary in the employment of the obstetric forceps, using it only in desperate cases, or cases not likely to terminate without artificial help. Dewes in 1826 protests against the frequent use of this instrument (to which even then practitioners were resorting oftener than he thought there was any warrant for), and declares that in his own practice he had not employed forceps oftener than once in three hundred and fifty

cases.¹ Davis considered the proportion of one in 53, which was approved by Professor Burns, as at least 400 per cent. too great, and was of opinion that the forceps is not required more than once in 300 or at most in 250 cases.² Denman in 1807 (the highest authority of the time) laid down a rule "that the head of the child shall have rested for six hours as low as the perineum";³ and Churchill, while thinking this a very practical rule, qualifies it by advising a resort to the forceps "when the second stage has lasted so long as to prove the inadequacy of the natural powers, or at all events so soon as the symptoms of a prolonged second stage make their appearance (quick pulse, dry tongue, fever, etc.)."⁴

In 1835, Dr. Robert Collins published his "Practical Treatise on Midwifery," in which he lays down rules for the use of the forceps: "In tedious labors when the mouth of the womb is fully dilated, the soft parts relaxed, and the head so low in the pelvis as to bring the ear within reach of the finger, if there be a necessity for interference, the forceps may be used with advantage." In 16,414 deliveries, he met only 14 answering to this description.

With the introduction of anesthetics into surgical and obstetrical practice, there has come a reaction against this conservatism, and a readiness not only to save suffering to the parturient woman, but *time* for the medical attendant, by an early application of the forceps. We have heard at medical meetings junior members of the profession boasting of the frequency with which they have applied forceps both long and short. We find even able obstetrical authorities, like Dr. Swayne of Bristol, England, expressing approval of the practice of using the forceps during the first stage of labor. He quotes Denman's injunction: "The first stage of labor must be completed before we think of applying forceps," and declares that "in no branch of obstetrics have we departed so much from the precepts and practice of our forefathers as in this."⁵

Dr. W. Jepp Sinclair, like his predecessor Dewes, calls a halt in this forwardness for instrumental delivery.⁶ The midwifery practice of the present day, especially among the working classes of England, is, he says, something to wonder at and deplore. The young practitioner sees a woman suffering under the pangs of labor; he can relieve these by anesthetics; normal labor is a process which requires time; the practitioner does not like waiting, and he has appliances by which he can abridge the process of normal labor; he knows that he may produce injuries, but these are in his eyes trifling compared with the injuries which he has been accustomed to see treated successfully by the surgeon with the aid of anesthetics, and a laceration can always be sutured if it appears to be of sufficient importance. Why, therefore, should he permit suffering to his patient and waste his own time?

⁵ Medical Press and Circular, January, 1876.

⁶ British Medical Association, Section Obstetrics and Gynecology, September 2, 1897 (Daily Journal of the Association, September 30).

He does not know enough of gynecological practice to be impressed with the importance of a laceration of the cervix or vagina, or a dislocation of the uterus, that is to say, of the remoter consequences of his well-meant interference. The current practice is, Dr. Sinclair thinks, vastly too meddlesome and mischievous, and some reform is urgently required.

In many of the manufacturing towns the proportion of cases in which the forceps is applied amounts to 25 or 30 per cent. and even more. The highest figure mentioned is 75 per cent. It is a common practice for physicians in the case of multipara to allow half an hour to an hour for the second stage of labor, and if the case does not show signs of immediate spontaneous completion, to put on forceps. He declares that among the gynecological cases at the Manchester Southern Hospital, it is by no means a rare thing to find a young woman suffering from a dislocation of the uterus, and lacerations of the cervix and perineum whose first labor was terminated by forceps within four to six hours of the onset of regular pains. In contrast with the high percentage of forceps cases in the obstetrical practice of many of his *confrères*, he cites the relatively low percentage at the Manchester Maternity Hospital: nine per cent. among the in-patients, 1.4 per cent. among the out-patients. The higher percentage of the in-patients is explained by the fact that the hospital beds are understood to be retained for cases of difficulty and danger; hence a large proportion of the women admitted have a history of difficult or operative labor in the past. The statistics of Bela-Von-Walla comprehending cases delivered with forceps in the University *Klinik* for Obstetrics at Buda-Pesth, from September 1, 1882 to December 31, 1895, give a proportion of 1.04 per cent. over the whole time, and in 1895 of only 0.32 per cent.

Wahl's account of the forceps treatment of labor in the Dresden Hospital deals with the cases delivered within the hospital from 1889 to the end of 1895, six years. The whole number of cases was 9,061; forceps were used in 232 cases, that is, two-fifths per cent. It is insisted, at this hospital, that the cervix shall be completely dilated, the membrane ruptured and the sagittal suture as nearly as possible in the antero-posterior diameter of the pelvic outlet. There were only 17 cases in the whole 9,000 in which the forceps were applied while the head was at the pelvic brim. The final indication for resorting to forceps was always danger to the mother, to the child or to both, and three to four hours was the period allowed for the second stage of labor.

Sinclair, who cites these statistics, calls attention to the number and extent of the lacerations and injuries which are attributable to the forceps under conditions in which observations could be exactly made. Munchmeyer reports 85 per cent. of lacerations, including all tears both trifling and severe. Schmidt found 84.6 per cent. of lacerations of the vagina and perineum, two of the latter complete in 132 forceps operations at the *Klinik* of Basel. Wahl, at Dresden, found 81.4

per cent. of injuries in 342 cases. There were lacerations of the cervix which required immediate suturing to stop the hemorrhage, and there were six complete lacerations of the perineum. Only 18 per cent. of the cases were uninjured. "Munchmeyer," says Sinclair, "may well refer to the application of the forceps as the bloodiest operation in medical practice, and Wahl quotes with approval the opinion of Von Winckel that even in the hands of an experienced operator the forceps is an instrument by no means devoid of danger."

Sinclair concludes that all we see and all we read seems to point to the fact that we have replaced the one great injury of parturition of former generations — vesico-vaginal fistula — by a host of others, vesico-vaginal fistula by laceration instead of by sloughing, and in addition to the lacerations are displacements which may come from them. There are numerous other acute and subacute troubles, such as parametritis and cicatrization.

MEDICAL NOTES.

DEATH OF THE DUCHESS OF TECK. — The Duchess of Teck, who it will be remembered was successfully operated upon last April for strangulated hernia by Dr. Herbert W. Allingham, has recently died as a result of the recurrence of the trouble.

THE PARASITE OF TRACHOMA. — The *London Daily Chronicle* recently announced that Dr. Leopold Müller, a professor at the University of Vienna, has succeeded in discovering the bacillus of the so-called "Egyptian eye disease." The affection meant can only be trachoma, since the micro-organisms of other contagious affections of the conjunctiva have been already identified. If true the discovery is important.

CLINICAL RECORDS. — A hedge doctor (a quack) in Ireland was being examined at an inquest on his treatment of a patient who had died. "I gave him ipecacuanha," he said. "You might just as well have given him the *aurora borealis*," said the coroner. "Indade, yer honor, and that's just what I should have given him next, if he hadn't died." — *St. Thomas's Hospital Gazette*.

YELLOW FEVER DECLINING. — On November 8th only fourteen new cases of yellow fever and six deaths were reported in New Orleans; and the reports from Memphis, Mobile, Montgomery and other points also showed a marked decline of the disease, which is doubtless due to the recent cooler weather in the stricken region. The raising of the shotgun quarantine has allowed the resumption of trade, and the situation has markedly improved in every respect. The sudden decrease from the recent average of fifty new cases daily in New Orleans is to be noticed.

LITTRÉ VS. THE VERNACULAR! — One winter's morning in Paris, thirty years ago, M. Depaul was making his visit in the *Cliniques* at eight o'clock. On approaching the bedside of a young woman in the lying-in ward, he said, "Bon jour, ma fille." — "Bon

jour, m'sieur." — "Avez-vous dormi bien?" — "Oui, m'sieur." — "Est ce que vous-avez uriné?" — "Je ne sais pas, m'sieur?" — "Avez-vous pissé?" — "Mais, oui, m'sieur, beaucoup."

DATES OF APPEARANCE OF FROST IN NEW ORLEANS. — In the *Public Health Report* for October 23d is published a table of the dates of the first killing frosts in New Orleans for the years 1873 to 1896. The earliest killing frost occurred in 1877, on November 11th, and the latest in 1887, on December 29th. The average date was December 7th. In Memphis the earliest frost occurred in 1876, on October 2d, and the latest in 1889, on November 29th, the average being October 26th. In Mobile the average date of the first killing frost is November 22d, in Montgomery, Ala., November 12th, and in Galveston, Tex., December 18th. In Vicksburg, Miss., the average date is November 10th. The figures are furnished by the United States Weather Bureau, and, as will be seen, furnish a fair indication for Edwards and vicinity.

YELLOW FEVER IN THE SOUTH. — The following statistics concerning yellow fever have been received in the office of the Supervising Surgeon-General of the United States Marine-Hospital Service during the week ended November 6, 1897:

		Cases.	Deaths.
ALABAMA:			
Mobile,	Oct. 30-Nov. 5,	74	5
Montgomery,	Oct. 30-Nov. 3,	25	3
Selma,	Oct. 30-Nov. 4,	1	1
Wagar,	To Nov. 3,	45	3
Whistler,	To Nov. 1,	25	2
LOUISIANA:			
Baton Rouge,	Oct. 22-31	3	1
New Orleans,	Oct. 30-Nov. 5,	266	54
MISSISSIPPI:			
Bay St. Louis,	Oct. 29-Nov. 5,	42	2
Cayuga,	Nov. 5,	1	..
Clinton,	Oct. 31,	2	..
County Farm,	Nov. 5,	1	..
Durant,	Nov. 1,	1	1
Edwards,	Oct. 30-Nov. 4,	4	..
McHenry,	Nov. 2,	1	..
Nitta Yuma,	Oct. 30-Nov. 4,	9	..
Pascagoula,	Oct. 30-Nov. 3,	6	..
Seranton,	Oct. 30-Nov. 4,	35	3
West Pascagoula,	Nov. 2 and 3,	8	..
TENNESSEE:			
Memphis,	Oct. 30-Nov. 5,	19	10

THE POLICEMAN AND THE EMPEROR. — A good (and true?) story is going the rounds which shows to what extent the violent ebullitions and caprices of the German emperor are regarded in his own country. An English gentleman, it appears, was walking with a friend in Unter der Linden, and in the course of a discussion on the kaiser's conduct committed a grievous error of Majestäts-Beleidigung. "The emperor's a — fool," he exclaimed, whereupon an English-speaking police officer tapped him on the shoulder and said, "You must come mid me to ze police station." — "What for?" asked the Englishman. — "Mein herr did call ze kaiser a — fool," replied the man. — "No, no," urged the acute Briton, "it was the Russian emperor I was talking about." — "Dat vill not vash," went on the constable, "dere is no em-

peror a — fool except the German emperor." After which, Dame Rumor has it, the police officer and the Englishman agreed to keep each other's secret, and parted on good terms. — *Westminster Gazette*.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, November 10, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 60, scarlet fever 25, measles 8, typhoid fever 14.

DEATH OF A CENTENARIAN. — Mrs. Cynthia Sewell, reported to be the oldest inhabitant of Bucksport, Me., died recently, aged one hundred years and two months.

BERI-BERI AT NEW BEDFORD. — The whaling barque *Greyhound* arrived at New Bedford November 4th after a five years' voyage. The crew were stricken with beri-beri about a month ago, of so grave a type that three of the number died and five others were brought into port still suffering from the disease.

NEW YORK.

ENTERTAINMENTS IN AID OF HOSPITALS. — On the occasion of the opening of the gorgeous new Astoria Hotel, on November 1st, entertainments were given in the afternoon and evening, under the auspices of a number of fashionable women, in aid of the Saturday and Sunday Woman's Auxiliary Hospital Fund, the Loomis Sanitarium for Consumptives, the Babies' and Mothers' Hospital, the Babies' Ward of the Post-Graduate Hospital, and two day nurseries, and it is said that over five thousand dollars was realized for these institutions.

POISONING BY JAMESTOWN WEED. — Three little boys, one aged four years and the other two six, while enjoying their Saturday holiday recently ate the seeds of some Jamestown weed growing on a lot at the corner of Riverside Drive and 79th Street, under the impression that the seed-pods were chestnut-burrs. As a result, one of them died and the lives of the other two were saved only with the greatest difficulty.

THE OLDEST VOTER. — The oldest voter at the recent Greater New York election was a hale and hearty old gentleman who will celebrate his 101st birthday on the 14th of December next. He is Prof. Emanuel Schwab, a native of Frankfurt-on-the-Main, and this is the fifty-third time that he has voted in America, where he came in 1840. He was a member of the Bar in Germany, but in New York has kept a school, which he did not relinquish until he was ninety-six.

DEATH OF DR. CHARLES H. AVERY. — Dr. Charles H. Avery, for many years Corresponding and Recording Secretary of the Medical Society of the County of New York, died at his residence in New York on November 2d, at the age of sixty-three. He was born in Perryville, Madison County, N. Y., and was graduated from the Long Island College Hospital in 1865. At

the time of the death of the late Dr. Wesley M. Carpenter, he was assistant secretary of the County Society, and then succeeded Dr. Carpenter in the office of secretary.

DEATH OF DR. JOSEPH E. CULVER.—Dr. Joseph E. Culver died at his home in Jersey City, N. J., on November 1st. He was seventy-four years old, having been born in Groton, Conn., on February 9, 1823, and was one of the best known physicians in Hudson County. He was graduated from the College of Physicians and Surgeons in 1849. He aided in organizing the Hudson County Medical Society, and had been superintendent of schools and treasurer of Hudson City before its consolidation with Jersey City. Four sons, two of whom are physicians, survive him.

THE LOW DEATH-RATE.—The mortality in the city has of late been very small, representing an annual death-rate of only about 16 per thousand of the estimated population. During the week ending September 25th the total number of deaths reported was 664. In October the highest mortality for any one week was 721, and the lowest 676. In the week ending November 6th there were 669 deaths. For the year 1867 the death-rate was 32.27, for the year 1871, 28.6, and for the year 1892, 24.26. Comparing some of the causes of death in the weeks ending respectively October 23d and November 6th, we find that the deaths from measles increased from 4 to 13, those from scarlet fever decreased from 8 to 7, those from diphtheria increased from 16 to 24, those from pneumonia increased from 73 to 77, and those from pulmonary tuberculosis decreased from 107 to 99. During the week ending October 23d there were two deaths from influenza, but none have been reported since. In the week ending October 23d there were three deaths from malarial fever, and in the week ending November 6th but one.

Miscellany.

MEDICAL EXPERT TESTIMONY: A PROPOSED LAW.¹

AFTER a conference with Judge L. A. Emery, of Maine, Regent Foster, Esq., of New York City, has drawn up the following proposed law intended to correct the abuse of Medical Expert Testimony in New York.

"An Act, in Relation to Expert Testimony," passed the — day of —, 1897.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. When in any civil or criminal proceeding it appears that the testimony of skilled experts may aid in determining any issues of fact, any justice of the Court in which such proceeding is pending may upon the application of either party and after reasonable notice and hearing appoint one or more skilled experts, who shall make such reasonable examinations and tests in relation to the personal thing or subject-matter involved as either party may request.

¹ Medico-Legal Journal.

SECT. 2. Such expert may be examined as a witness at the trial by either party or by the Court, and shall receive for his services and for his attendance at court a reasonable sum, to be fixed by the Court and paid by the party making the application, and be taxed in his costs if he recover.

THE MAIDSTONE EPIDEMIC OF TYPHOID.

THE number of cases of typhoid fever in Maidstone, England, had reached 1,748 by October 27th, and thus this epidemic only finds one parallel in the modern sanitary history of England. That parallel, according to the *Lancet*, October 30th, is the case of Worthing, where, during an epidemic period of seven months, from May to November, 1893, as many as 1,411 attacks were recorded; and both in Maidstone and in Worthing the vehicle of the disease has been a public water-supply. It might be difficult to hold the Worthing Corporation directly responsible for the distribution of the enteric fever poison by means of their water-supply, because the infection that reached the water in that case was the result of accidentally meeting a fissure in the chalk during works carried out to improve, or at least augment, the water-service. But after the event it became clear that the wells sunk as they were in so fissured a stratum as the chalk, had become surrounded by houses, sewers and drains, as the result of the extension of the town, to such an extent that the supply ought to have been looked on with suspicion. Anyhow, a terrible object-lesson was afforded of the results liable to ensue on the infection, whether as the result of neglect or by accident, of a public water-supply.

THE SEPARATION FOR DIAGNOSTIC PURPOSES, BY A NEW METHOD, OF TYPHOID BACILLI FROM THE STOOLS AND URINE.

THE Health Department of the City of New York issues a circular of information regarding the separation for diagnostic purposes, by a new method, of the typhoid bacilli from the stools and urine in cases of typhoid fever, to the following effect:

The examination of specimens of blood from cases of suspected typhoid fever for the Widal reaction has been of great assistance in diagnosis. Occasionally, however, the agglutinating substances do not develop in the blood at any time, or only very late in the course of the disease, or an earlier infection cannot be excluded, owing to the lack of a reliable previous history. In these instances the Widal test fails to give the information desired.

Bacteriologists have long sought for a rapid and certain method of obtaining and identifying in pure culture the typhoid bacillus from the stools and urine in cases of typhoid fever; but hitherto without satisfactory results. Dr. Hiss, Assistant Bacteriologist to the Health Department, has devised a method, by which it is believed it will now be possible to recover and identify the typhoid bacilli within less than forty-eight hours, from specimens of feces and urine containing them. The Health Department desires to thoroughly test this method and is prepared to undertake these examinations, if proper specimens are furnished.

While definite knowledge is lacking as to the number of typhoid bacilli usually present in the stools of typhoid patients, and as to the time of their appearance and disappearance, it is believed that they are generally present in the discharges, not only during the height of the disease, but also, though to a less extent, at its commencement and

for a considerable time during convalescence. The appearance of the bacilli in the urine is usually later than in the feces. The experience thus far obtained seems to indicate that the bacilli may be obtained from about 50 per cent. of all cases on the first examination, and from about 90 per cent. after repeated examinations. The Health Board hopes that these examinations will prove of value, not only for diagnostic purposes, but also in solving important sanitary questions relating to the presence in and time of disappearance of the bacilli from the stools during convalescence.

Physicians are requested to send specimens of intestinal discharges and urine from well-defined cases of typhoid fever, and also from all doubtful cases in which the Widal test has failed to give definite information.

It must be understood that, as yet, these investigations are largely experimental; but that when the typhoid bacilli are isolated in culture an absolute diagnosis of typhoid infection is obtained.

Care should be taken to send, if possible, a specimen obtained from a natural movement, or one following a simple enema. No disinfectants, of course, should be employed. If the movement is formed, the portion from the part last passed, that is, the portion coming from highest up in the intestine, should be selected. In cases complicated by colitis, care should be observed to avoid, if possible, the selection of a specimen composed largely of mucus.

The specimen is collected by seizing a small portion of the discharges between the two slips of wood accompanying the outfit, and placing this in a bottle. The top of the bottle is replaced and the specimen returned to a culture station or to the laboratory.

Specimens of urine should be received directly into the bottle accompanying the outfit, or should be collected in an absolutely clean vessel and immediately transferred to this bottle, which is then returned to a culture station, or to the laboratory.

The necessary outfits, with directions and blanks, may be obtained at the various Health Department depots, where diphtheria culture tubes, antitoxin and other products are supplied. Blanks which should be fully filled out in every case accompany the circular.

THE WIDAL TEST FOR THE DIAGNOSIS OF TYPHOID FEVER.

THIS same department also issues another circular of information regarding the Widal test for the diagnosis of typhoid fever, in which we find these statements:

The results of a very large number of examinations made here in New York and elsewhere show, that if the blood contains agglutinating substances in sufficient amount to cause a prompt and marked reaction, when one part of serum or blood solution is added to *ten parts* of a broth culture of the typhoid bacillus, the presence of a previous or existing typhoid infection may be considered as probable, and that if these substances are present in such an amount as promptly to produce the reaction, when one part of serum or dried blood solution is added to *twenty parts* of the culture, the presence of a previous or existing typhoid infection may, for diagnostic purposes, be practically considered as established.

In estimating the diagnostic value of a negative result from this test, we must remember that the reaction is rarely, if ever, present until at least four days after the appearance of symptoms; that it is occasionally absent in cases of typhoid fever until the third or fourth week, or even until convalescence is established; that when developed it may disappear after a few days, and that no definite relation between the severity of the disease and the degree and time of development of the substances causing the reaction has been established. For these reasons a single negative result in any suspected case only renders

doubtful the existence of typhoid fever. In those cases in which the reaction is absent after the sixth day, it may be reasonably assumed that the large majority will not prove to be typhoid fever, and the absence of the reaction in all of several different cases of a suspected group, or after repeated examinations in any single case, affords evidence of very decided value in excluding the diagnosis of typhoid fever.

Either dried blood or the serum obtained from a blister may be sent for examination. The serum can be more accurately tested than the dried blood, and whenever possible this should be furnished for test. Outfits for preparing both kinds of specimens may be obtained at any of the Health Department depots.

There follow directions for preparing specimens of blood, and directions for obtaining specimens of serum from blisters.

FRACTURE OF PATELLA BY A SURGEON DURING FORCIBLE FLEXION.

ARTHUR POWELL, B.A., M.CH., reports in the *Indian Medical Gazette* the case of a Mussalmani woman, aged twenty-eight, who was admitted to hospital for stiffness ("fibrous ankylosis") of the right knee-joint, caused by synovitis two years previously, and in whose case this accident occurred.

A slight amount of passive movement existed; the patella could be moved laterally, showing no adhesion to the tibia or femur. The patient was well-proportioned, taller and stronger than most of her race.

There was no evidence of syphilis, scrofula, rickets, mollities, scurvy, malignant or other disease to account for fragility of the bone.

Chloroform was the anesthetic. Manual force alone was employed, and no snap was heard other than is ordinarily caused by the rupture of fibrous adhesions.

A peculiar dimpling over the patella was noted, and examination showed that the bone had been broken into three fragments. This was very clearly made out by palpation immediately after the accident, before any effusion took place.

This case is reported by the writer as unique; but, as he remarks, "it is possible that similar cases are not unfrequent, though the surgeon is too bashful to record his experience for the warning of others."

The case is the more remarkable, as no pulley or apparatus of any kind was used. The writer adds that he is at the best of times of weak muscular development, weighing only nine stone, and on that occasion was weak with influenza.

APHORISMS.

(A LONG WAY AFTER HIPPOCRATES.)

Ὁ βίος βραχὺς, ἡ τέχνη μακρὰ, ὁ καιρὸς ὀξὺς,
ἡ πείρα σφαιερὴ, ἡ κρίσις χαλεπή.

(1) LIFE is short, the curriculum long; examiners treacherous, tips fallacious; fees exorbitant, diplomas valueless.

(2) Of making many treatises there is no end, and a superfluity of lectures causeth ischial bursitis.

(3) Whoso seeketh appointments seeketh grief and heart-burning, for the thyrsis-bearers¹ are many but the inspired few.

(4) The art consists in three things: the disease, the patient, and the house-physician.

¹ A term applied to the general body of worshippers in a Greek [Bacchic] temple.

(5) He that would acquire a competent knowledge of medicine ought to be possessed of the following advantages: Natural ability, competent instructors, favorable conditions for study, early tuition, idomitable perseverance, ample capital.

(6) General practice is harassing, specialism lucrative, midwifery laborious, life assurance responsible, hospital measures radical.

(7) Dentistry is golden, ophthalmology cleanly, throat-work sanguinary, otology circumscribed, pessary practice debasing, hygiene elevating, clubs demoralizing.

(8) Whoever would prosper in private practice must first master all these: must possess presence of mind, gentlemanly manners, true sympathy, an iron constitution, an even temper, a head for figures, knowledge of human nature, a devoted wife.

(9) The successful practitioner understands three things: the digestion of infants, the nervous organization of women, the infirmities of age.

(10) The physician is a frequent worshipper in the temple of the dead, but the surgeon's memory for mortal cases is ephemeral.

(11) The physician recognizes the limits of his art, but the surgeon discredits himself by attempting the impossible.

(12) A scientific operation requires three conditions: accurate diagnosis, carefully-planned details, patient nursing.

(13) The most acute cases are those which are suitable for the surgical wards; the next most acute are suitable for the septic wards; after these come cases suitable for clinical; then those suitable for the medical wards; cases more chronic than these are cases suitable for another hospital; and if there be any others yet more chronic than these, they are eminently fitted for a parish infirmary. — *Guy's Hospital Gazette*.

THERAPEUTIC NOTE.

A NEW LOCAL ANESTHETIC. — A. Einhorn and Heinz¹ describe the new synthetic local anesthetic, orthoform. This body is a white, light powder, without smell or taste. It is only partially soluble in water, but enough is brought into solution to make the fluid anesthetic. It combines with hydrochloric acid, forming a very soluble compound, which cannot however always be used, as it irritates some mucous membranes, such as the conjunctiva. Anesthesia is only induced in the places with which the orthoform comes in contact. Orthoform acts as an anesthetic wherever it comes into contact with nerves, and thus it has no effect when applied to the unbroken skin. If it be applied to a burn of the third degree, the anesthetic effect is remarkable. It also allays the pain of ulcers, whether cancerous or other. In one case as much as 50 gm. was sprinkled on a wound within a week, showing that it is quite harmless. It is strongly disinfectant, hindering decomposition and fermentation. Orthoform was also useful in ulceration of the larynx; after some of the powder was blown in the pain was relieved for twenty-four hours. In gastric ulcer and carcinoma it was also of service, but much less so in chronic gastric catarrh. For external use the free orthoform is the best, but for internal use the soluble acid salt. Further observation is needed in regard to its action on the mucous membranes of the mouth, nose, and naso-pharynx. As it is non-poisonous, it can be applied to large ulcerating surfaces. Internally, $\frac{1}{2}$ to 19 of the hydrochlorate has been given several times in the day. Orthoform is stable, non-hygroscopic, and can be added to other remedies.

Münch. med. Woch., August 24, 1887.

METEOROLOGICAL RECORD

For the week ending October 30th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,726; under five years of age 912; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping cough, erysipelas, and fevers) 384, acute lung diseases 357, consumption 306, diphtheria and croup 147, diarrheal diseases 109, typhoid fever 46, scarlet fever 29, whooping-cough 17, cerebro-spinal meningitis 9, measles 9, erysipelas 4.

From scarlet fever New York 14, Philadelphia, Brooklyn and Cincinnati 3 each, Boston, Cleveland, Pittsburg, Providence, Cambridge and Newton 1 each. From whooping-cough New York 9, Brooklyn 4, Pittsburg 2, Washington and Charleston 1 each. From malarial fever St. Louis 5, Brooklyn and Nashville 3 each, New York 2. From measles New York 7, Philadelphia and Pittsburg 1 each. From cerebro-spinal meningitis New York 4, Baltimore, Boston, Worcester, Lynn and Somerville 1

each. From erysipelas Philadelphia 2, Providence and Springfield 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending October 23d, the death-rate was 16.9. Deaths reported 3,572, measles 91, diarrhea 82, diphtheria 81, fever 79, scarlet fever 49, whooping-cough 47.

The death-rates ranged from 11.6 in Derby to 22.7 in Wolverhampton; Birmingham 20.0, Bradford 13.1, Cardiff 13.8, Gateshead 12.4, Hull 15.3, Leeds 19.0, Leicester 14.6, Liverpool 20.5, London 16.8, Manchester, 19.5, Newcastle-on-Tyne 17.7, Nottingham 13.4, Portsmouth 13.1, Sheffield 18.5, Sunderland 16.9.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 6, 1897.

ADRIAN R. ALFRED, passed assistant surgeon, detached from waiting orders at his home, Jeddo, Mich., and ordered to Marine Recruiting Rendezvous, San Francisco, Cal.

P. FITZSIMONS, surgeon, ordered to duty as a member of the Board of Inspection and Survey, Washington, D. C., November 8th.

G. D. COSTIGAN, assistant surgeon, detached from the "Lancaster" and ordered to the "Indiana."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING NOVEMBER 4, 1897.

MURRAY, R. D., surgeon. To resume command of Service at Mobile, Ala. November 2, 1897.

KALLOCH, P. C., surgeon. To rejoin station at Cairo, Ill. November 4, 1897.

CARRINGTON, P. M., passed assistant surgeon. To relieve Passed Assistant Surgeon B. W. BROWN as acting chief clerk of Bureau. November 4, 1897.

COBB, J. O., passed assistant surgeon. Upon completion of duties at Camp Fontainebleau, Miss., to rejoin station at New York, N. Y. November 3, 1897.

BROWN, B. W., passed assistant surgeon. Relieved from duty as acting chief clerk of Bureau, and directed to report to the director of the Hygienic Laboratory for duty. November 4, 1897.

CLARKE, TALIAFERO, passed assistant surgeon. Upon being relieved by Surgeon P. C. KALLOCH, to rejoin station at Chicago, Ill. November 4, 1897.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 490 Boylston Place, on Monday evening, November 15th, at 8 o'clock.

Drs. A. L. Mason and H. L. Burrell: "Hydatid Cyst of the Liver."

Dr. J. L. Morse: "A Study of Thirty-seven Fatal Cases of Cirrhosis of the Liver."

Dr. A. Thorndike: "Spina Bifida Ruptured during Birth, Recovery."

Dr. J. P. Clark: "Complete Congenital Occlusion of the Posterior Nares, with the Report of a Case."

JAMES G. MUMFORD, M.D., *Secretary*, 197 Beacon St.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology and Hygiene will hold a regular meeting at the Medical Library, 19 Boylston Place, Wednesday evening, November 17th, at 8 o'clock.

At 8 P. M. Short communications: Drs. Cheney and J. L. Morse.

At 8.30 P. M. Dr. W. W. Gannett: "Yellow Fever"; Dr. W. T. Councilman: "Pathological Anatomy of Yellow Fever."

E. W. TAYLOR, M.D., *Secretary*, 416 Marlborough St.

BOOKS AND PAMPHLETS RECEIVED.

Lecture.

FRACTURES OF THE LOWER JAW AND THEIR TREATMENT.¹

BY DR. P. W. MORIARTY,

Instructor in the Mechanical Treatment of Fractured Jaws and Cleft Palate in the Dental School of Harvard University.

GENTLEMEN:—In the treatment of fractures of the lower jaw it is important that the members of our profession should be thoroughly informed upon the subject. Many of you after leaving the school may never meet with a case, but a dentist, especially in the smaller cities or towns, is liable to be called upon at any time to treat a fracture, either in co-operation with the surgeon or alone.

The surgeon finds that fractures of the lower jaw are the most troublesome to treat; he is not able to apply a splint in the same manner as in fractures of other bones. He finds that the numerous muscles which control the movements of the jaw tend to displace the fragments. The muscles which govern the tongue, larynx and the neck, when used, also tend to displacement.

The displacement is produced primarily by the force which caused the accident, secondarily by muscular contraction. If the fracture be at the median line, there will be little or no displacement, as the muscles of the one side have no advantage over those of the other side.

The muscles which are most active in causing displacement are the masseter, the internal-ptyergoid, the mylo-hyoid, the genio-hyoid, and the genio-hypoglossus.

Any decided movement of the head, either rotary or otherwise, will have a tendency to displace the fragments. The simple acts of deglutition and speaking also tend to do the same. In the act of swallowing the larynx is elevated by the contraction of the hyoid muscles, which are attached to the tongue and the styloid process of the lower jaw. Before the contraction can take place the lower jaw must be fixed to the upper by the muscles which fix the mouth, when the act may be accomplished.

I have not time this morning to go further into the action of the muscles in the various kinds of fractures.

The inferior maxillary, from its exposed position, its shape, and its office, is more subject to fracture than the superior maxillary.

There is a wide difference as to the most frequent location of fractures of the jaw.

Ehrichsen claims it occurs more frequently at the symphysis than at any other point, while Boyer makes the statement that it never occurs there, but at the weakest part of the bone, that is, on each side of the symphysis, but as long ago as Hippocrates, fracture at the symphysis was known and recognized.

Garretson says the weakest part is on a line with the roots of the cuspid, with an unbroken dental arch, but where the teeth have been removed the weakest part may be at the point of their removal.

Gibson claims that age has much to do with location, and that in the young it is commonly at the symphysis.

From my experience, I have found that the location of the fracture depends upon the direction of the force

necessary to cause a fracture, and the position of the teeth remaining in the jaw.

Fractures of the ramus are rare. This exemption may be accounted for by the protection given by the muscles and the integument, and the natural strength of the bone, also the force of the blow is often broken by the joint slipping out of place. Fracture at the ramus is more liable to occur in patients whose upper teeth are all missing or who wear a poorly fitting upper plate.

Many cases of fractured neck of the condyle are recorded, and, as a rule, are most serious, as you may get fatal brain complications.

Fractures of the alveoli are common, but are not considered serious unless unusually extensive.

Fractures are simple when the bone only is divided without piercing the integuments.

Fractures are compound when the injury is accompanied by laceration of tissue through which there is a communication between the external air and the fracture. This form is most common, and the laceration exists upon the lingual side; or when the integument is lacerated, it is most generally from gunshot wounds.

Fractures are comminuted when the bone is broken or crushed into several pieces at the same point, and communicating with each other.

Fractures of the jaw are unmistakable, the prominent symptoms being pain, swelling, drooling and crepitus, with but little hemorrhage unless the fracture is compound. There is also displacement of the fragments, which the irregularity in the line of the teeth plainly shows. You may also have increased salivation. Of course, the loss of function is apparent when the patient is unable to use the jaw.

If the inferior dental nerves and vessels are injured you may get paralysis, facial spasms, etc. Drs. St. George, Holmes and Ehrichsen, who have had some experience in such cases, never met with any paralysis connected with the injury to the soft parts; whilst Boyer, Berard, Heath and Chelius in their works claim the opposite.

When any doubt exists as to the location of a fracture of the lower jaw, grasp the bone on each side with the forefingers introduced into the mouth and resting upon the teeth; you will then have no difficulty in recognizing the false point of motion or crepitus between the fragments.

Fractures of the lower jaw are of quite frequent occurrence and are generally the result of direct violence. In men a fall, a kick from a horse or a blow from a policeman's club or from the fist being the prominent causes. In women a blow from the husband has been the cause in every case we have had at the school.

In my opinion, the dentist and not the physician or surgeon is the proper person to treat all fractures of the jaw. Dentists should emphasize this fact, and impress it upon the public and the physicians. That the hospitals are recognizing this fact is proven by the number of cases we have had here during the past few years.

In the early days various methods of treatment were resorted to. The teeth were not considered as essential to the health, comfort and good looks of the patient as now. It did not matter if the contour of the face was marred by the displacement of the fragments. If the parts grew together fairly well it was

¹ A Lecture delivered at the Dental School of Harvard University.

of little consequence if the articulation was good, bad or indifferent. If one or more teeth were prominent and made the displacement noticeable, the forceps in the hands of the surgeon soon remedied that, and the patient was thankful to get through alive.

The physician treats a case of fracture of the jaw by applying a four-tailed bandage, or by wiring the parts together. The dentist treats one by means of a dental splint nicely constructed and properly applied, which is far superior to bandaging or wiring. Physicians seem to be unaware that the comfort and interests of their patients would be better served by calling in the services of a dentist.

The application of a correctly made splint does not interfere with the functions of the jaw, and in a great many cases the patient can masticate with comfort, being able to open and close the mouth. This they cannot do when bandages are used.

The best treatment requires the readjustment of the fractured parts, and fixation, and that the fixation of the bone shall not interfere with its functions, nor with the required dressing of an associated wound.

When a patient with a fractured jaw comes to us we

FIG. 1. Simple vulcanite splint, with boxes vulcanized on each side.

thoroughly wash the mouth with an antiseptic solution, any very loose teeth are removed, and the teeth cleansed from tartar.

An impression of the upper jaw is taken in modelling composition, and one of the lower or fractured jaw in modelling composition or plaster. No attempt is made to put the fragments in proper position.

Plaster casts are made, on which the lines of fracture are clearly indicated. With a fine saw the cast is cut on these lines, and the lower teeth are articulated with the plaster cast of the upper jaw. Plaster is run around to hold the severed portion in position, and then both upper and lower casts are put upon an articulator.

The process of waxing up and making a vulcanite splint is similar to that of making a vulcanite plate, and is familiar to you all.

I find that for fractures at the symphysis the simple dental splint is sufficient (Figs. 1, 2 and 3).

I always vulcanize on the sides of the splint boxes, into which wire arms can be inserted. These wire arms are bent at the corners of the mouth and extend back towards the ears; a bandage from each arm and under the chin gives the pressure required to hold the parts in position (Fig. 4).

If the jaw is fractured in the region of the molars,

considerable pressure is required to get the parts in position. This I obtain by the addition of a mental splint or chin-piece (Fig. 5).

This is well padded and by a number of screw-bolts attached to the wire arms; and the pressure is gradually increased until the fragments are in the correct position (Figs. 6, 7, 8).

In one case that I had during the past year, the patient, who wore an upper and lower set of artificial teeth, had the lower jaw fractured on the right side at the cuspid, and on the left at the first molar. Using the lower plate for a splint, boxes were vulcanized on the side, the arms and chin-piece attached, and a good result was obtained.

In another case in which the patient did not have any teeth (Fig. 9) the fracture was at the ramus. As can be readily imagined, this case necessitated a bandage; but in order to maintain the correct relationship between the upper and lower jaw, an interdental splint, with an opening for the reception of food, was inserted, and the patient bandaged.

Fourteen days later the splint was replaced by an upper and lower set of teeth, and ten days later the patient was dismissed, the union being complete.

That the best constructed splint may be a failure was forcibly brought to my attention in the case of one patient who came to the infirmary with a fracture between the left lower cuspid and bicuspid, and at the angle of the jaw on the right side. Considerable pus exuded from a sinus on the left side. A vulcanite splint with metal chin-piece was applied, and at the end of a week the flow of pus had apparently ceased.

On the ninth day the splint was not in position, the mouth was foul, and pus freely flowing again. Believing that the patient did not properly cleanse his mouth, and being unable to explain the failure of the splint, I removed it and applied a four tailed bandage.

Annoyed and perplexed, I made inquiries, and was informed by an acquaintance of the patient that he with a pair of pliers had loosened the appliance after leaving the infirmary and tightened it again before coming to see us.

The patient at first stoutly denied doing this, but finally admitted that he did, as he could not see why it was necessary to keep such pressure on his jaw.

The great disadvantage that we as dentists labor under in the treatment of some of those cases is that we have no place where patients who are in need of nourishment can be attended. For instance, a homeless patient, or one who boards out or in a café, cannot very well sit down to table with this appliance on his jaw. Or the patient may be feverish and need constant attention; this he cannot get except in some place where he will be looked after.

I have in the cases of some private patients used a modification of the Angle system, but prefer wider bands. I do not approve of banding the lower to the upper teeth except in a few cases, the objections being that in order to feed the patient it would often be necessary to extract a tooth, and that you do not give the patient any use of the lower jaw.

There are many ways of treating a fracture of the jaw other than bandaging, which is the natural device of the sufferer. Barton's, Gibson's, Hunter's, and the four-tailed bandage have done excellent service.

In several cases where the fracture was at the symphysis, with but little displacement, I have used a continuous cap of gold or aluminum cemented onto the

FIG. 3. Shows mouth open, with the splint on the teeth, allowing patient to masticate food with but little discomfort.

FIG. 5. Splint, arms and chin-piece. Pressure is obtained by tightening the screw-bolts which run from the arms to the chin-piece.

FIG. 11a. Plaster model, showing articulation of a fractured jaw before treatment.

FIG. 11b. Plaster model of same jaw, showing articulation after treatment.

FIG. 6. Side view of splint, arms and chin-piece in position.

FIG. 8. Appliance on, showing how the mouth can be opened to enable patient to eat, drink, etc.

FIG. 7. Front view.

FIG. 9. Fracture of the ascending ramus. Patient without any teeth. Inserted an interdental splint to maintain correct relationship between upper and lower jaw, also bandage and small chin-piece.

FIG. 12a. Plaster model of jaw, showing displacement before treatment.

FIG. 12b. Plaster model, showing articulation after treatment.

teeth. The cap is struck up by die and counter-die from a reconstructed plaster cast of the fractured jaw. This is very neat, is not noticeable, and gives excellent results (Fig. 10).

Wiring the parts together has been tried frequently and often successfully. Wiring the teeth has often been a dismal failure.

Metal plates and ligatures have been used with more or less success.

I have not perhaps given you anything new, but I want to impress upon you the fact that the dentist can do this work better than any surgeon.

FIG. 10. For simple fracture a continuous capping of gold, aluminum or other metal cemented onto the teeth.

We utilize the work of our predecessors, and perhaps simplify it.

I believe that the time is coming when the treatment of fractures of the jaw will be so systematized and simplified that any dentist will be able to handle the most difficult cases.

During my eight years' service at the school I have found that the average student, under proper instruction, quickly grasps the methods to be pursued in the treatment of any deformity, many of which are more complicated than the treatment of a fracture of the jaw.

I have here models of 28 cases showing condition before and after treatment, which I invite you to inspect.

To conclude, I am firmly convinced that the best treatment of a fractured jaw requires the services of a dentist who can make a splint or appliance adapted for each case (Figs. 11, 12).

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.—At the seventh annual meeting of this society, held at Harrisburg, Pa., the following officers were elected: President, Dr. Charles R. Dickson, 343 Sherbourne Street, Toronto, Ontario; First Vice-President, Dr. Frederic Schavoir, 8 Atlantic Street, Stamford, Conn.; Second Vice-President, Dr. Caleb Brown, Sac City, Iowa; Treasurer, Dr. Richard J. Nunn, 119½ York Street, Savannah, Ga.; Secretary, Dr. John Gerin, 68 North Street, Auburn, N. Y. The next meeting will be held in Buffalo, N. Y., on September 13, 14 and 15, 1898.

Original Articles.

THE "SKIN-HEART" AS A FACTOR IN THE HUMAN CIRCULATION: WITH SPECIAL REFERENCE TO THE BRAND AND SCHOTT TREATMENTS.

BY WOODS HUTCHINSON, A.M., M.D.,
Professor of Comparative Pathology, University of Buffalo.

IN tracing the pedigree of our mammalian vascular system, from its earliest ancestral form, as well as through its embryonic stages, we have solely to deal with the familiar process of division of labor and centralization of power. Beginning originally with the network of irregular "chinks" between the cells, which become walled by a simple, flattened, protoplasmic tissue, and this, as the surrounding cells lose to some degree their powers of contraction, developing into circular bands of muscle-cells, each ring of which drives the blood onward, vermicular-fashion, we find this universal contractile power gradually concentrating itself, in one or more regions, with the result of the formation of a heart or hearts in these localities. So that, finally, in the mammalian circulation we have the result of one large, thick-walled dilatation of the original tube, known as the heart, guarded by an elaborate series of valves, propelling the blood through an apparently comparatively passive system of blood-tubes. We say "apparently passive," because even the briefest study reveals the fact that these tubes are highly elastic and to a degree which could only be possessed by living tissues, and that this elasticity plays a most important part in the circulatory mechanism. Secondly, that the calibre of the arteries and arterioles, particularly the latter, varies very considerably from time to time, so as to markedly influence the flow of blood to the part supplied by them. The reactions are obviously carried out by the presence of the elastic coat which forms the chief bulk of the wall in the aorta, and gradually diminishes in importance down to the arterioles; and the changes of calibre are equally obviously brought about by the vital contraction or relaxation of the firm and powerful muscular wall, which extends from the largest arteries down to the mouths of the very capillaries themselves.

This much of actual vital contractility is unanimously granted by all physiologists to the muscular cells of the arterial walls; but here their power apparently abruptly stops. And, while fully realizing that we are in a position to little more than raise the question, we wish to emphatically challenge this position, and assert not only the possibility, but also an apparent high probability, that these muscle-cells are possessed of far wider powers than those with which they are usually credited. In the first place, no one questions the fact that they are as thoroughly alive, responsive and capable of vigorous action as any other unstriated muscle-cell in the body, and it certainly is against all the analogies of what we know of muscular action everywhere else that they should be capable only of such mechanical changes as will merely regulate the calibre of the tubes which they surround. We know of absolutely no form of muscle which is capable of that form of sustained and uniform contraction; everywhere else muscular action is rhythmical—very slowly so in some cases, it is true, but still emphatically rhythmical; and only in a few tetanic, spasmodic conditions is it capable of maintaining a uniform contraction-level for more than a very brief period.

of time. And yet this theory presupposes the extraordinary power on the part of the muscular cells of coming to a given point and retaining their contraction practically unchanged, not only for hours, but for days and even weeks. The position becomes still more untenable upon *a priori* grounds when we remember the extraordinarily active part which is played by this very same muscular wall throughout the entire circulatory system of the higher invertebrates and the lower vertebrates, and that the heart is nothing under heaven but a simple localized aggregation of these very same muscular fibres. That this heart-forming tendency is not limited to any one locality, but may occur in two, four, six, or even eight different places in the body, that we still have, even in some of the highest mammals, those singular pulsating, spongy net-works known as *retia mirabilia*, such as are found upon the collateral branches of the carotids in the horse, and which unquestionably appear to act as local balance-wheels of the circulation. It would also seem not improbable that our own elastic, muscular and highly-pulsating spleen performs some such pressure-regulating function for the portal circulation. In fact, we cannot resist the conviction that this extraordinarily universal and vigorous muscle-coat in our arteries and veins has a higher vital function than merely that of mechanically narrowing the calibre of the vessels. As Wesley Mills aptly expresses it, "An inherent tendency to rhythmic contraction, all through the vascular system, including the vessels, must be taken into account."¹

While this dissatisfaction with the usually accepted view of human physiologists was manifesting itself at the comparative end of the line, upon the extreme opposite wing of the army of medical progress, among the clinicians and the therapeutists a similar though less articulate feeling was developing itself. We have long been conscious of the utter inadequacy of most of the explanations of the extraordinarily tonic and beneficial effects of bathing, or splashing the surface of the body, with cold water. The familiar "reaction" theory has been growing more threadbare every year; for, if it simply consists in throwing more work upon an already exhausted or overloaded central organ, its ultimate effects would necessarily be that of our boyish attempts to lift ourselves by our boot-straps. Not that this element does not play some part in the result, but that it is utterly inadequate to account for the general glow of satisfaction, the feeling of comfort and permanently tonic effect which is brought about by this simple but wonderfully effective means. Why the blood should remain for not merely minutes, but even hours, in the superficial vessels, with less effort on the part of the heart than before the plunge or splashing is, of course, hardly to be accounted for simply by any tonic effect upon the heart or central nervous system; but when this remedy began to be systematically applied in therapeutics, the gap between the theory and the results became wider still. In the Brand treatment of typhoid fever, for instance, while we were at first inclined to regard almost the whole of its beneficial effect as due to a mere mechanical lowering of the temperature and quickened escape of abnormal bodily heat, one after another our clinicians have come to the conclusion that this is one of the least of its beneficial effects, and that the singularly tonic effect which is produced upon the heart and nervous system and the renal excretion is the central factor in its

wonderful power. All the leading authorities upon this method of treatment—Baruch, Osler, Seiler, Stockton—have expressed themselves most definitely to this effect. In the words of the last: "It is not simply a question of reducing the temperature, for it cannot be too strongly insisted that while the temperature is an extremely important and constant accompaniment of these states and changes it is far from being the most serious or the most important of them. In fact, it is to be regarded, both in its rise and reduction, as only an index of the more important and active conditions which are going on deep in the interior of the body. So far as the mere reduction of temperature is concerned, the Brand method offers probably little advantage over the antipyretic drugs, but its remedial superiority lies chiefly in the effect it has upon the underlying factors. Authorities are agreed that the chief factor in its curative effect is not the mere mechanical reduction of the temperature, as such, but the marked improvement in tone, first in the peripheral cutaneous and then in the general vascular system. This it is which drains and empties the engorged lymph-spaces of their poisoned food materials, that relieves congestion in the hepatic and pulmonary circulations, that throws the full volume of blood through the anemic, paralyzed kidneys."

Still more recently, in a widely divergent realm of therapeutics, this method has been applied, and with even more surprising results: first, in the treatment of the toxic heart-failure of pneumonia; and, second, in the so-called Schott method in the treatment of valvular heart-disease. In the latter of these the effect upon the vascular mechanism is much the same as before—the application of cold or cool water to the body surface. This, however, is rendered more stimulating, first, by the addition of considerable quantities of salt, chiefly such as will be found in sea-water; and, second, in the later stages by the introduction of that unrivalled stimulant to unstriated muscle fibre, carbonic acid. In this last case we have obviously the temperature factor completely eliminated, and the nervous system as such almost equally so; for these patients are usually in a fairly good state of equilibrium, with but the one defect, the inadequacy of their great heart-pump. So marked is the effect of this skin-heart tonic, that in severe cases of dilatation the almost incredible result is attained, of causing the apex to retract three-quarters of an inch towards its normal position in a single bath. Not only are the pulsations of the heart greatly lowered in frequency, but apparently increased proportionally in power, so that the work, which was previously altogether too much for it, is performed with comparative ease and comfort. In fact, the results obtained from this simple remedy sound almost too good to be true, and would hardly be believed, if the repeated experience of competent clinicians did not almost unanimously verify them.

Now, it seems to me that on no possible theory which regards the heart as the sole motive-force of the circulation, and the heart-muscle as the only muscle in the vascular system possessing powers of rhythmic, propulsive contraction, can more than the merest fraction of any of these three great classes of results be explained. But, suppose we recognize the power already suggested, of constant rhythmic contraction upon the part of the muscular tissue *wherever found* in the vascular system,—grant this, and it seems to us that

¹ Animal Physiology.

the problem in all three cases is wellnigh solved. The voluminousness and functional importance of the great mesh of blood-vessels in the skin and subcutaneous tissue, its importance as a heat-regulating and excretory factor, have been insisted upon by all physiologists; and if, in addition, we have the right to regard this enormous mesh, capable of containing nearly thirty per cent. of the entire blood of the body, as endowed with the power of independent contraction in its muscular walls, we have at once a factor in the circulation which could be depended upon for the production of some most striking results. In fact, we venture to claim that in the blood-vessels of the skin and underlying tissues we have in the higher vertebrates, just as everywhere in the lower forms of life, a great "skin-heart," which plays an important part in the circulation, not only in health, but also in disease. For instance, in the effect of the Brand baths, the fact that the local stimulant effect upon the vessels of the skin is promptly followed by a rapid reactionary dilatation is as familiar as the alphabet; but just why this reaction should so immensely improve the quality of the heart's action and relieve the toxic condition of the whole nervous system is as yet hardly accurately explained. It is usually accounted for simply on the ground that it relieves the work of the heart by dilating the skin-vessels and diminishing peripheral resistance.

But Winternitz observes, what a glance at the flushed skin of the fever patient would immediately suggest to the eye, that we have already a distended condition of the peripheral blood channels due to paralysis of the vessel walls, and insists, in flat contradiction to the other explanation, that the heart's action is improved by the *restoration of resistance* in the peripheral circulation. But let us once admit that the fundamental element in this so-called "improvement of the tone" in the superficial vessels, the appearance of which all investigators agree upon, is really an active and not a passive one, a local rather than a reflex change, and the problem is solved. In other words, the normal condition of the muscles in the walls of the arterioles, and of the ameboid contractile endothelium of the capillaries is not one of rest, either in contraction or dilatation, but of constant rhythmic activity, and that the restoring of this active contractivity in the vast mesh of vessels in the skin, by the contact of the cold water and by friction, is the essential element in the improvement of the circulation. The heart itself is nothing but a special local aggregation of these same muscular fibres, and like them, its action is intrinsic and merely *regulated* by the so-called cardiac nerves; and, when we recall that the great contractile mesh of the cutaneous vessels is capable of containing over thirty per cent. of the entire blood of the body, and that the whole of this surface is affected by the cold bath, it hardly seems impossible that the stimulation of this great, diffuse "skin-heart" may be a factor of the greatest importance in improving the entire circulation. Once this active addition to the total force of the circulation has been effected, the relieving of the lymph toxin-stagnation in all the tissues and organs follows rapidly. The nervous system, rid of the torturing poisons with which it has been saturated, most rapidly feels the relief. Sleep now becomes possible, and is simply the beginning of the benefits which will flow from this gain. The digestion is distinctly improved by the relief of the portal stagnation,

and another important line of connection with the relief column is opened up. The marked improvement in the nerve, determination and courage of the patient is but a striking symptom of the similar change which is taking place throughout the whole organization, and is of itself an immense gain in the struggle back to health. The kidneys are flushed by an abundance of blood, which both nourishes and stimulates them to increased excretory efforts. The glands of the skin, freed from the singular choking effects produced upon their spinal excretory ducts by the lymph stagnation in the surface tissues, resume their activity, and, according to Quirolo, the toxic properties of the sweat of fever patients are almost as well marked as those of their urine, and so the entire situation is modified in the right direction.

Now let us see of what assistance this hypothesis would be in explaining the remarkable effects of the Schott-Nauheim treatment. Upon what would these cool baths, with a high percentage of saline constituents in them, rendered still more stimulating by the addition of carbon dioxide, and prevented from depressing or chilling the system by passive movements and gentle friction, be most likely to act? Obviously, upon the great skin-mesh. And, when we remember that we are practically plunging the cells of this entire skin-heart into their old, ancestral medium of sea-water, and adding to it the one remedy which most powerfully increases peristaltic action on the part of any of the unstriped muscles of the body — as seen in animals poisoned by it — carbon dioxide, could we imagine anything which would be much more likely to stimulate to its highest degree of vigorous contraction, and restore to its molluscan and crustacean, long-swinging, tireless rhythm, the great skin-heart?

The first shock of the cold stimulates the whole mesh to contract forcibly and drive on the stagnant blood, not merely through the arterioles, but, by acting upon the unquestionably contractile epithelium of the capillary walls, through the capillary system, by a similar stimulation of their linings and walls through the lymphatic and venous systems, the lymph which has become poison instead of food to the tissues. This, when thrown into the right side of the heart, provides the greatest stimulus for contraction of the ventricular muscle, namely, active dilation by an abundance of blood. The lungs do their part in purifying, and return it to the left side of the heart, from which it is driven in abundant flow through the kidneys, thus accounting for the marked increase of urinary secretion after this treatment. But if the action ended here, we would only be a little better off than before, for upon the principle usually accepted, the superficial blood-vessels, having contracted, would remain for a considerable length of time in the same condition, and the heart would simply have to overcome on the arterial side precisely the same amount of force which had been added to it upon the venous. Suppose, however, that the contraction has been a rhythmic one, and that the vessels have dilated in readiness for this increased supply of purer blood. The moment they have received it they again promptly, no matter how slowly, contract and drive it on again into the great veins. That this rhythmical contraction, as evidenced by a healthy flush of the skin, is steadily increased by the continued restoration of ancestral conditions, the vigorous sea-bath which the vessels are receiving, is evident; and it seems to me

that we really have a new force added to the circulation, something like an adequate explanation of how the weak and distended ventricle can succeed in retracting its apex half or three-quarters of an inch toward the median line during a single sitting.

We would again insist upon the fact that neither in typhoid nor in cardiac inadequacy can these effects, or anything like them, be produced by cold alone (for that has been thoroughly tried in both cases), by the temporary application of water alone, of whatever temperature, or by either dry saline, gaseous or mechanical irritants. It is absolutely necessary that not merely cold, but cold water, should be used; that the surface should be literally soaked in this for a considerable length of time; while the effect is markedly increased by the addition of the sea salt, and still further by carbonic acid, such as would result from abundant processes of oxidation in the water. In fact, fanciful perhaps as the suggestion may seem, it is by a precise and accurate imitation of our most ancient ancestral surroundings, in cool sea-water of high degree of salinity and a considerable percentage of carbon dioxide—in short, precisely the condition which we find in the shallow sun-warmed lagoons in which life probably originated—that we reach the maximum of curative effect.

I have been greatly pleased to learn upon writing to our leading American authority upon hydrotherapy, Dr. Simon Baruch, that his experience has led him to an almost identical view; that, as he expressed it, the cold bath gives rise to an "active dilatation" of the skin-vessels, an "active hyperemia, by reason of which the blood is propelled more vigorously through them;" that "the Almighty himself could not have created an apparatus possessing sufficient force to propel a viscid fluid like blood through the fine vessels of the skin, did not the latter possess propulsive powers," and that some such hypothesis as the "skin-heart" could be of great value in explaining some of the perplexing points in hydrotherapy.

Now let us see for a moment what basis of probability exists for the presence of this factor in the present state of our physiological knowledge. Although, as I confessed at the beginning, little more than suggestions of its possibility can be given, yet there are several of these. In the first place, all observers for the last thirty years have reported from time to time the appearance of rhythmic contractions in certain groups of the vessels of the lower forms, not merely in the invertebrates, but also in the lower vertebrates, even in mammals. The further we go down the scale, the more frequent this becomes. In fact, in the invertebrates it may be regarded as the rule. Among the lower vertebrates the vessels in the wing of the bat, in the fin of the eel, in the fins of various fishes, and in the foot-web and mesentery of the frog have been seen repeatedly to possess the power of constant though slow rhythmic contraction. In many cases this has been reported without any apparent suspicion of its real nature—as, for instance, when the arterioles of the frog are reported to seem to "vary spontaneously," and when, as Curtiss states, in watching the capillary area in a rabbit's ear, "capillaries not noted before may suddenly spring into view," and shortly after disappear. Among mammals almost every observer has commented upon, with varying resultant opinions, the singular rhythmic contraction frequently observed in the ear of the rabbit, and

occasionally in the mesentery of the same animal. Curtiss also admits that the capillary walls are evidently "living cells and possibly contractile." Porter declares that there has been much discussion over the rhythmic contractions present in some of the vascular areas of mammals; and these are but a few of dozens of admissions of at least the existence of such contractility (or occasional signs of it) in the mammalian blood-vessels.

Of course it hardly needs to be said that it is only very occasionally that the opportunity for observing this process in the mammalian tissues can be obtained; and with the single exception of the ear of the rabbit, in which every observer has noticed it, the placing of the tissues in a position to permit of this change being noted, if it occurred, would necessitate a very serious disturbance of the normal relations and even of vitality. It is, to my mind, significant, to say the least, that in the only places in the mammalian kingdom in which this phenomenon might readily be studied with the parts in their normal condition—the wings of the bat and the ear of the rabbit—it has been noted, and in some cases quite extensively speculated upon, by almost every observer. In fact, as Mills sums up the discussion of this phenomenon, "Such facts lend some color to the view that the return of vessels to their previous size after distension by the cardiac systole is aided by the rhythmical contractions of the muscle cells in the walls."² But we must also admit that nearly every investigator who takes the trouble to definitely pronounce upon this question expresses himself practically in the words of Marrant Baker: "There appears to be no reason for supposing that the muscular coat assists to more than a very small degree in propelling the onward current of the blood."³

Finally, are there problems in the physiological aspects of the circulation which remain conspicuously unsolved, and in which this factor might play a part? There are three at least. One of them is the much disputed question of the dicrotic wave in the pulse, which has usually been explained as a reaction wave upon the part of the elastic coat of the vessels, as an oscillation reflected from the periphery, as a percussion wave from the closing of the aortic valve, and upon a variety of other grounds. Upon closer examination, this wave is usually found in reality to consist of a low pre-dicrotic and a higher dicrotic curve; and we cannot resist the suggestion that we have here precisely the condition which would be accounted for by supposing that the first return of the blood-vessel to its normal calibre was carried out mechanically by the elastic tissue in its walls producing the predicrotic oscillation, while its return was completed by the active muscular contraction of the muscular coat producing the dicrotic wave proper. Moreover, this condition of affairs is exaggerated and retarded by lowered arterial tone; by which is meant a relaxed condition of the muscular coat, and consequently a free and complete distention, followed by a slow contraction of wider range, corresponding to the degree of distention. In conditions which increase the arterial tone, in which the distention from yielding is slight, and the reaction so prompt as to practically coincide with the recoil of the elastic tissue, not only are the two waves merged in one, but their beginning is so nearly synchronous with the cessation of

² Animal Physiology.

³ Kirk's Physiology, p. 207.

distention that the downward curve is practically uninterrupted, and the dicrotic wave almost disappears in high arterial tension.

I have been assured by my colleague, Dr. Hopkins, that he became convinced some years ago, as the result of an extensive study of sphygmographic tracings in the wards of the Buffalo General Hospital, that some active participation in the propulsion of the blood upon the part of the arterial wall was absolutely necessary to in any way adequately explain the phenomena of the dicrotic wave, and all physiologists are agreed with Porter that, "although the origin of the dicrotic oscillation has been much discussed, it is not yet satisfactorily settled, important as the bearings of such a decision would be."

And, last of all, there are certain reactions in the wonderfully complex and interesting problem of the maintenance of the blood-pressure which still lack anything like satisfactory explanation on the usually accepted hypothesis of the passive relation of the arterial walls—for instance, the familiar increase of general arterial pressure where an increased amount of blood is being driven through a part—precisely the opposite of what would be expected by one on *a priori* grounds, from the action of the vessels were they mere passive conducting tubes. This has usually been lamely explained by calling into play that mythical power of the long-suffering heart of increasing the work done by it in direct proportion to the resistance offered to it; which, if true (except for a very limited period), would place it upon a perfectly abnormal pinnacle of virtue. Suppose, however, that this increase of the arterial pressure is due to the active propulsive pressure which the muscle wall is exerting upon the blood, and that its contractions occur at the same rate with those of the heart, but in the intervals between them, and we can at once see how the blood-pressure may be distinctly raised and yet the work of the heart not only not increased but diminished thereby.

In fine, we would venture to submit these conclusions, as a basis for further investigation and discussion:

First, that the existence of active contractility upon the part of the muscular wall of the arteries and arterioles and in less degree of the veins and lymphatics, and of the capillary epithelium, is something which we have the strongest reason to expect upon ancestral grounds in even the highest mammals.

Second, that the beneficial effects upon the circulation of cold water, particularly of a high degree of salinity and accompanied by friction, first in health, second in the Brand method, and third in the Schott-Nauheim method in cardiac disease, are only adequately to be explained upon the ground of the persistence of such a power in our mammalian skin-heart.

Third, that the occurrence of this sort of contraction is almost uniform in invertebrates, and has been observed in the vascular area of many of the lower vertebrates—frogs and fishes, and in those positions in which it could be readily seen under normal conditions in the higher vertebrates, namely, the wing of the bat and the ear of the rabbit. So that we have abundant grounds for the possibility and some even for the probability of its occurrence in our own species.

Fourth, that in the behavior of the vessels in health, as noted by physiologic investigators, there are again conditions which are confessedly unexplained, and yet which may be accounted for on this supposition—the rhythmic pulsation of the vessels in the rabbit's ear,

the restoration of normal tone on the part of the vessels of any area after recovery from section of the vaso-motor nerves, the persistence of contraction in the ventricle in lower vertebrates and auricle in all forms after the section of all the cardiac nerves, the phenomena of the dicrotic wave, and the anomaly of an increase in the rapidity of the circulation and amount of blood in a given part, coinciding with marked increase of the arterial resistance.

NOTES UPON DENVER WEATHER.

BY CARROLL E. EDSON, A.M. M.D., DENVER, COL.

Miss —, aged seventeen years, came to Denver in March, with a history of tubercular invasion of the right lung, complicated with a recent serous pleurisy which had been aspirated a few weeks before. The right chest moved but slightly on respiration, and over the lower two-thirds was flat on percussion, with faintly heard breathing only on forced inspiration, slight tactile fremitus, and increased voice transmission. Over the upper third there was marked dullness, prolonged expiration and many moist rales. There was some cough, with about two drachms of expectoration in the morning. Tubercle bacilli present. The girl was pale, lips slightly cyanotic. There was marked anorexia and lassitude. The temperature was 101°, the pulse 120.

One month later my record reads: "Right side expands well. Percussion still very dull, but respiratory murmur of fair quality, heard to the base. Above, a few clicks after cough; the cough is slight and occasional. There is no expectoration. Temperature 99°, pulse 96. Color good. Appetite excellent. Has gained four and one-half pounds."

I do not report this case even thus briefly because the patient has improved so much more than was to be expected—there are frequently cases which happily correct our prognosis, and many which, with every promise of recovery, grow steadily worse—but because of another incident in the history. She was advised by a most competent consultant not to come to Colorado at that time, but to postpone her residence here until autumn, for the reason that the spring was the worst period of Colorado's year—rainy and windy.

There was certainly, in view of the history and condition of the patient, a grave doubt as to her improvement even in Colorado; but there is implied in the reasons for delay in coming a great misunderstanding of Colorado weather, a misunderstanding which, from frequent expression among the invalids sent to us, is apparently widespread.

The meteorological data of Colorado have been carefully tabulated and set forth for comparison with other places; but, as Mr. Ward has well said in a recent paper,¹ "A medical man ought to know how to interpret climatic tables. . . . It is not enough to know the mean annual rainfall. This should be supplemented by data as to the kind of rainfall, whether general rains lasting for some hours at a time, or thunder-storms, giving a heavy precipitation in an hour." Such details are not readily tabulable, and are too frequently unmentioned in the formal discussion of climate. I wish to supply a few comments, marginal notes as it were, to the more elaborate articles previ-

¹ Teaching of Climatology in Medical Schools, Boston Medical and Surgical Journal, February 4, 1897.

ously published and accessible, to describe that part of our climate which affects the patient as "weather," and influences his daily life and spirits. Simple as some of my statements may appear, they have yet proved surprisingly novel to many new-comers.

Denver is a high altitude station, situated just one mile above sea-level. It is not, however, *in* the mountains, or even among the foot-hills, as so many suppose before coming, but lies open upon the plains, fifteen miles from the first line of hills. Its open situation frees it from the diurnal up-and-down draught of a mountain valley, and its long day of sunshine is unbroken by the shadows of surrounding peaks. This distinct advantage in the matter of sunshine has a very practical relation to the daily life of an invalid. In Davos, which lies at the same elevation as Denver but in a valley sheltered from the winds by surrounding mountain heights, the sun does not rise on January 1st till 10.03 A. M., and sets at 3 in the afternoon. As Dr. Wise says, "An additional hour's sunlight during the short days of December and January is an inconceivable delight." Denver stands out from the mountains on the slope of the plains to the east. The sun has no high peaks to climb, but the first rays which tinge the snowy summits of Rosalie, or of Long's, are the immediate heralds of his rising. Up over the level eastern horizon there is no delay in the warm cheering of the daylight. On January 1st the sun rises at 7.19 A. M.; on December 1st at 7, and February 1st at 7.07. The sun is up before the invalid is awake, and a cheerful sunny sky greets his first vision. By 8 or 9 the air is warm, so that by the time he is up and dressed he can be out of doors. Over two hours of warming sunlight at the very first of the day without waiting—it is like waking in a warmed room instead of having to get up and make a fire first. Nor is the day shortened in the afternoon. The fifteen miles "set-out" from the mountains distinctly lengthens the day. Even Colorado Springs suffers in the comparison. On January 1st the sun does not set till 4.49 P. M.; nine hours and a half of sunshine.

This early sunrise with its invigorating cheery opening of the day cannot be valued too highly. With the morning depression so common in tuberculosis, the sense of effort in getting under way, a brilliant, sunny sky and a warmed air are of great mental as well as physiological benefit to the patient.

The promise of a sunny day is well kept, 70 per cent. of the possible sunshine being realized, while the partly-clouded days are by no means unsuited to an outdoor existence, and are often a grateful change to the patient from the intensity of cloudless blue sky. Patients often come here with an idea firmly impressed on their minds that we have but forty cloudy days in a year, a popular fallacy not easy to trace, and if there is the least little cirrus cloud to be seen, exclaim that they have been lured here under false pretenses. We do have cloudy, stormy days. No habitable region of the globe has none. There are as few here as in any place accessible to an invalid. The past winter has been considered as cloudy a one as we have had for several years, certainly the least pleasant of the last three; yet in December there were but seven days when the sun did not shine at all, only two when it rained or snowed, and the percentage of sunshine was 69. January had five all-clouded days, five only with rain or snow, and 65 per cent. of sunshine. February had seven completely clouded days and but

nine with any precipitation at all; its sunshine was 64 per cent. It is not a bad region where during the three winter months the sun shines on four out of every five days!

The marked diathermancy of the air, due to the altitude, with its barometric pressure of 24.74, and the great dryness (an absolute moisture of but 1.89 grains to the cubic foot) renders the sunshine very intense and penetrating. Conversely, the air from this same dry clear tenuity has little heat-holding capacity. Denver is not a warm place; its winter climate is distinctly cool. Its mean annual temperature is 49° F.; that of Boston is 48° F. In no other feature does the Colorado climate so often prove disappointing to the newcomer, or is it so misrepresented to the prospective sojourner as in this of the winter temperature. He is not coming to, nor should he expect to find, a tropical climate. The mean January temperature for twenty-five years is 28° F. This, of course, includes the night temperatures, which are always very low. The invalid, however, is not affected by these night temperatures, and the daytime averages are the important ones. The air in winter is clear, sharp and cold; but its great dryness makes it easily borne and even very pleasant. Its tonic effect upon nutrition and metabolism is from this very coolness the more marked and the more desirable in early tuberculosis. In the shade there is the tingle of northern cold, and the heaviest clothing is none to warm. The sunshine, however, tells another story. Its direct, unrefracted rays burn strongly, and the temperature of the sunshine ranges nearly 60° higher than the air. It is this glory of warm sunshine which is so much praised in Colorado, and which is so often misunderstood to refer to the air. The patient sent to Colorado for a winter is not coming to a soft, balmy warmth, but to a far better, sharp, bracing cold, flooded during two-thirds of the daytime with a blazing sunshine.

This tremendous difference between sun and shade, day and night, has been objected to as making a trying climate for an invalid. The night temperature may be neglected as the patient is indoors. The day changes between sun and shade are much mitigated by the extreme dryness of the air, which renders the extremes of heat and cold less noticeable. It does necessitate explanation to the inexperienced, and an intelligent conduct of living. A change from sun to shade must be met by extra wraps. As heavy clothing, that is, underwear and suiting, should be worn in winter here as in Boston; but the summer overcoat need never be put away. The changes of temperature are best met by the outer garment. In winter one who is in active outdoor life finds great convenience in three overcoats—a thin summer coat for noontime (though frequently none is needed), an ordinary winter coat for early morning and afternoon, and, for any long or night ride the heaviest of ulsters or fur coats.

Precipitation and humidity statistics are the favorite tables of climate papers. Attention should be called to one factor in their interpretation. Denver has an annual precipitation of a trifle over fifteen inches, about one-third that at Boston or New York, less than half that at Chicago, and three-tenths that at Jacksonville, Fla. But the total amount of rainfall is not alone a true measure of the dampness. In Colorado, especially on the eastern slope of the mountains and on the plains, it falls upon a dry and porous soil thirsty for any moisture. It is absorbed with great rapidity,

and in a few hours the ground is dry and hard again. About Denver there are some areas of clayey soil which for a day or two after a *heavy* rain are muddy — not thin and sloppy, but a good, stiff, gluey mass which clings to boots and clothing with more than brotherly closeness. There are no standing puddles, and often forty-eight hours after a rain the dust will be blowing on the roads. In winter when the precipitation is in snow, the advantages of the dry soil and air are especially marked. There is no accumulation of snow at Denver; a few days, rarely a week, and all traces of it are gone, save on the northern side of banks or walls. There is never any sleighing here. The wind from the south or west licks up the snow with visible rapidity without its melting into slush or icy pools. Indeed, it evaporates rather than melts. It does not house the invalid save while it is falling; and a few days gives dry, bare roads again. As there is no accumulation, there is no melting season in the spring to be avoided, as in Davos or Saranac. There is sunshine enough without a heavy mantle of snow to give reflected radiation, and its absence allows greater opportunity for outdoor exercise in winter, and offers no threat in spring.

Objection is frequently made to Denver as a residence for invalids on account of its wind: a curious example of the popularity of a fallacy. A study of the very full statistics of the Weather Bureau for over five years shows that of the sixteen largest cities of the United States Denver has a less total wind movement than any of them, with one exception. The mean annual movement of the wind here in Denver is 62,000 miles. Boston shows 101,000, New York 96,000 and Chicago 136,000. A study of these records, the details of which I propose to discuss in another paper, shows that the wind movement here is very regular, and has an average velocity of 7.2 miles an hour. With this must be taken into account the greater lightness of the air at this elevation — but fifteen-nineteenths of that at sea-level — a decided factor in the apparent force of the wind.

The occasional dust-storms are unpleasant, but are much less frequent and severe than popular accounts would indicate. They are becoming less frequent, too, as more of the land comes under cultivation. Moreover, they do not depend upon the velocity of the wind, but apparently upon some peculiarity of angle at which the air current strikes the ground, enabling it to pick up the fine soil. This must be remembered, as it is too often thought that every high wind means a dust-storm, which is by no means the case. This winter we have had but two worth considering, both of comparatively short duration — a few hours only. In 1895 there was a period of four days of almost continual dust — an exceedingly trying time, necessitating an invalid being housed. This was an unusual occurrence. The ordinary dust-storms last but an hour or so, and are no worse than some of the March days in Boston, and without the cold, piercing wind. The storm, so-called, is usually but a limited period of extremely dust-filled air, in the midst of an often cloudless, sunny day.

The common impression that Colorado climate is seasonal is erroneous. What little bad weather we have is fairly evenly distributed throughout the year. Indeed, a common remark of residents is that we miss the sharp contrasts between summer and frosty autumn, or winter and the balm of spring. There is no

well defined spring, as in the East. There is no accumulated snow to melt and uncover the fresh earth. The winter weather gradually becomes less cold, then distinctly warm; the days are longer and one wonders when the buds will be out. The sun is very warm by day, but the nights are still cold. Suddenly, in a day or two, the trees are all in leaf, and it is summer. Similarly the summer passes into winter without the frosty crisp of a New England autumn. The air is too dry to be snappy. It may almost be said that one is on the watch for the cold and roughness of winter, and is at last aware by the return of birds and summer that the winter he expected has already passed.

As in other parts of the country, there is, of course, more uncertainty in the weather during the spring months. About one-third of our total precipitation occurs in the three spring months; but it does not come as a prolonged rainy spell, but from short, sharp showers, or in thunder-storms of brief duration. There is never the long, cold drizzle. The mornings during April and May are almost invariably pleasant, with clear blue sky dotted with rising white clouds and fragrant with the delicate perfume of the new alfalfa. The afternoon or early evening often brings a short, brisk rain, but the ground is hard and dry again by morning. The short, curly buffalo-grass of the plains does not stay wet, as the long, heavy grass of New England.

The three spring months show an average of twenty-four clouded days, or but eight a month. Nor do these mean a day indoors for the invalid; for it must be distinctly understood that an overclouded day does not mean rain of necessity or a blustery storm. The heat of the sunshine is removed, and the invalid may need an extra wrap. Many speak of these clouded days with gratitude, as being a restful change to the eyes from the unbroken blue intensity of the sky. These all-clouded days are not lost to the invalid's recovery — as the tables are too often interpreted, as though when the sun were not out no one else could be. To many, they bring a pleasant refreshment in a sense of lessened nervous tension. Those of us who are long here often speak of the restfulness of a day of clouds. That they do not mean storm or wet, an interpretation of published figures will show.

This spring (1897), as I have said, has been considered unusually cloudy. In March there were 23 cloudy days; yet there were but nine on which .01 of an inch of rain fell, and the total fall was but .9 of an inch. The actual sunshine was 64 per cent. of the total possible. The unyielding skeleton of figures in columns must be clothed with intelligent features to be recognized as a friend.

The summer is hot but pleasant. The sun is strong and direct; but while the solar heat registers not infrequently 140°, the mean temperature of the air at 1 P. M. is but 85° in July, 81° in August, and but 72° in September. This temperature is rendered even less apparent by the dryness of the air — even the sunshine being endurable, while the shade is always comfortable. The relative humidity of the summer months is but 45 per cent. as against 71 per cent. in Boston, 74 per cent. in New York and 76 per cent. in Chicago. Collars do not wilt, and the dryness of the air may be realized by the fact that there is no dew deposit on soda-water fountains or ice-pitchers except rarely, just after a shower or rain. Sunstroke is unknown in Colorado. The nights are always comfort-

able, and the refreshing sleep renews one for the next day. You do not start exhausted.

When autumn comes by the calendar, it is known only by a more delightful charm of air. From September to Christmas there is an almost unbroken period of delicious, sparkling days. There is not the snap or zest of a New England fall—a beauty which it alone possesses—but there is the delight of warm, dry air dancing full of sunshine. The foliage does not turn to the brilliant hues of the East, but shows a beauty of dull reds and yellows and soft deep browns, which must be seen to be appreciated. The mountain slopes and uplands appear as if spread with the richest of Persian rugs.

Winter shows the dull expanse of gray, brown plains occasionally blanketed for a day or two with snow, just long enough to give zest to a rabbit chase. With its clear, sunny, blue sky and cold, dry air, it is little more than an expectancy between summer and summer.

Taking the year round, a few facts of such ordinary interest that they are rarely mentioned will show how evenly good the weather is. In the year 1895—an average year—a friend went with his bicycle club upon its weekly Sunday run fifty-two times; not once was that excursion prevented by storm or snow or impossible roading. The open street-cars run all the year round, and the days are few when they are too exposed for riding.

NOTES ON SURGICAL GAUZES.¹

BY HERBERT J. HALL, M.D., MARBLEHEAD, MASS.

THE study of textile fabrics, of their capillarity and other purely physical characteristics, in relation to surgery, is a department which at present receives less attention than it deserves.

It will not be considered an unreasonable supposition that the success or failure of certain operations in surgery may depend upon the speed or slowness of capillarity in the gauze used as a dressing. The surgeon knows all about his patient, all about his asepsis: pathology and bacteriology are his allies. He knows practically nothing about his dressings, beyond the fact that they are sterile and absorbent.

Sterilization is carried on under personal supervision. It is not trusted to a stranger. Absorbency—a no less important faculty of gauze—is left in a general and trusting way to a manufacturer who knows nothing about surgery and whose principal aim is profit.

It is the object of this paper to consider with some care, from the surgeon's standpoint, the capillary power of the various commercial gauzes. Gauze and drainage are so closely associated that some reference must necessarily be made to the latter subject. We may be confident that we are using good gauze, or we may not consider at all whether one gauze is better than another. At any rate, if we have no definite knowledge of the capillary power of the gauze which we use, we are trusting rather too largely to the honesty and intelligence of the manufacturers of cotton cloth. If the gauzes are uniformly excellent, it will be a comfort to know it. If they vary in any marked degree, we should not be long in choosing the best.

Taking a one-hundred-yard roll of absorbent gauze,

such as is furnished by any dealer in surgical supplies, we will see if throughout it possesses an even and rapid capillarity. Probably the most practical way of doing this, and the one least likely to error, is to determine by weight, the amount of water absorbed in a given time, under given conditions, by a strip of gauze of given dimensions. A little frame of wire has been devised, to which the strip of gauze can be attached and an equal degree of immersion obtained in each case.

A piece of gauze six inches long and one-half inch wide, containing in most fabrics fifteen longitudinal threads, is found to weigh, for example, two grains. When it is stretched double on the little frame we have a wick of thirty strands. The double end of the gauze is immersed in water, to the depth of one-quarter of an inch, for a period of sixty seconds. Taken from the frame, its new weight is found to be three and one-half grains. The difference between these figures equals one and one-half grains, and is the amount of water absorbed by this wick, under our chosen conditions. This is the principal method used in testing the various gauzes.

For convenience, when we have made a number of such tests in a given gauze, we will strike an average of the weight of water absorbed by the different strips and call that figure the average capillarity of the gauze in question.

Returning to our one-hundred-yard roll, we select three samples, not containing selvage, from remote parts of the gauze, and we find, after a number of tests, that the wicks vary a good deal in capillarity. If now we cut strips, side by side, from the same width of gauze, we shall see like differences in absorbency.

Plain, unsterilized gauzes from four hospitals were examined in the above manner, and certain rather striking averages obtained. It was believed that sterilization, especially the baking process, would make some difference in the absorbent power of the gauzes. Therefore, the hospital gauzes were tested, after being sterilized, by the two common methods—baking and steaming. The averages showed in some instances increase in capillarity by steam, and in others a diminution. A like result was obtained with the baked gauzes. All these differences, it was believed, might fall within the limit of initial variability in different parts of the same sample of gauze.

Disregarding the sterilizing and taking the results of nine immersions of each plain gauze, we make the average capillarity of

Massachusetts General Hospital plain gauze	4½
Children's Hospital, Boston,	4½
Carney Hospital, South Boston,	4
Salem Hospital	3
A gauze submitted by Sampson & Padelford, of Allston, gave an average of	3½

It is a common belief that a perfectly dry gauze will not absorb so well as a moist gauze. An apparent proof of this assumption is seen when we throw a dry gauze sponge into a basin of water. Such a sponge will float for some time and we say it does not readily absorb water. It is true that a moist sponge will sink at once, but this, as will presently be granted, is because, being moist, it already contains nearly water enough to make it sink. If a dry strip of plain gauze, like those described, absorbs, for example, three grains of water under the given conditions, we have shown by repeated trials, that the same strip of gauze, thoroughly

¹ Read at the February meeting of the Essex South Section of the Massachusetts Medical Society.

and so out of the line of progress. In the open gauze the transverse threads are long and, having quite as much capillarity as their longitudinal brothers, they carry far in the wrong direction large amounts of fluid. In the selvage when the drainage strikes a transverse leader, its lateral excursion is short and frequently intercepted by longitudinal threads, so that progress is almost uninterruptedly upward.

A homely, but convincing demonstration of the soundness of this reasoning can be made with ink, a medicine-dropper and a piece of blotting paper. Cut a piece of blotter one-fourth of an inch wide and the length of the width of an ordinary insurance blotter, and place five drops of ink in the middle of the strip. There are practically but two directions in which the ink can travel. The color will run along the strip for about two inches. Place in the middle of a broad piece of blotter the same number of drops, and you have a circular blot, with a diameter about half the length of the first blot. The first part of this simple experiment illustrates the action of the selvage in absorption. The second part is analogous to the action of the open gauze.

In this connection we should mention wicking or cordine, which, according to this principle, has a decided advantage over ordinary gauze wicking, as it contains in small compass a maximum number of longitudinal threads. In proportion to its bulk it is, perhaps, the best wick we have, as it will absorb, even when drugged with iodoform, thirty-three grains against perhaps eight grains, by a gauze wick, which would fully occupy the same space.

Dr. Thayer says further in his article: "It was also observed that the same number of strands as contained in the other drains, with the warp removed and the woof made into a wick, possessed no advantage over either the plain or medicated ganges as to its power to drain fluid."

The wicking, or cordine as it is called, and also the selvages which have been considered, can scarcely be compared to a fabric with its woof removed, because they are more compact in structure, and the close proximity of the threads must be an advantage. In these structures, if there are any spaces they are tubular and capillary. If one thread ceases to absorb, its neighbor can quickly take up the work.

A study lamp which burns a pint of oil in an evening may teach a lesson in drainage. In most lamp wicks the threads all run as nearly longitudinally as is consistent with stability of the fabric.

We are now confronted with some plain facts about surgical gauzes. The commercial product is not only uneven in capillarity, but the very weave of the stuff makes it unsatisfactory for drainage purposes. We must bear these things in mind when we apply our dressings.

Steps have already been taken toward securing the manufacture of an absorbent tape on the principle of the selvage. Such a tape, it is hoped, will supplant the faulty gauze drain. Where walling off is necessary, a gauze woven with twice or three times the number of threads running longitudinally would help in making a safer dressing.

In the light of what we have seen, the most appropriate place for the ordinary absorbent gauze is in the so-called receiving mass, where lateral distribution is rather an advantage.

However high the index of absorption may be in an

iodoform gauze, we may safely say that it would be higher, if the iodoform were left out. Therefore, if we need rapid drainage, we should not use iodoform gauze.

It is a comfort to know, experimentally, that dry sterilization does not lessen the absorbency of gauze.

Whether we are able to better ourselves or not, we should not, in such a field as surgery, be ignorant of our limitations in any direction. If we have gone over the ground, if we know where we stand, we shall be able to make more intelligent use of a faulty material, until we are supplied with something which will serve our purpose better.

New Instruments.

A NEW ELECTRICAL NASAL SAW.¹

BY FREDERIC C. COBB, M.D., BOSTON.

In presenting a new electrical nasal saw it is of importance to recapitulate the work already done in this direction.

The first mention I have found of such a saw is in the "Transactions of the Laryngological Association" for 1887. Dr. Roe, of Rochester, exhibited a saw of this kind having a somewhat elaborate and expensive mechanism. In the following year these defects becoming evident to him, he modified the saw, making its mechanism more simple. This saw had a vertical driving-wheel and was connected to the flexible by a spring. To this saw the main objections seem to me to be the liability to kinking or "buckling" of the spring when resistance is put on the mechanism. Its lateral attachment to the flexible also tends to throw it out of plumb.

Next came the chain saw of Veeder.² This was a saw intended to cut vertically. The great difficulty in keeping such a complicated mechanism clean and aseptic will, I think, be evident to any one examining it carefully.³

Black followed this by a description of a saw very similar in many respects to the one shown by me, the main difference being in the lack of ability to stop and start it from the handpiece.

Schepppegrell, in April, 1897, exhibited a saw⁴ improving upon that of Black's in this respect, but one which seems to me more complicated in its mechanism.

The great disadvantage of all electric saws has been the lack of power to control them. Such a saw should be strong, and not too light, so as to give as little vibration as possible, offering a firm grasp to the hand, and so arranged that it can do no damage if it gets beyond control.

The saw shown in the cut is very strong, and its mechanism is simple, consisting only of a wheel with piston attachment connected with the saw. The length of the stroke is altered by turning a screw on the driving-wheel. It is easily cleaned and oiled, the cap on the driving-wheel being hinged so as to be easily removed for that purpose. A friction clutch on the handle, as suggested by H. M. Sweet, of Boston, enables the operator, by removing the little finger from a spring, instantly to stop the action of the saw while

¹ Read before the Laryngological, Rhinological and Otological Society, at Washington, May 2, 1897.

² New York Medical Journal, February 21, 1891.

³ Laryngoscope, July 1, 1896.

⁴ Loc. cit., vol. xi.

the motor still continues at full speed. Pressure on this spring at once starts the saw, whatever the position of the motor. Every operator in nasal work knows the strain of arm and hand to which one is subjected in removing a long, thick and bony spur. In the use of this saw attention need only be given to the direction and the work is accomplished much more quickly than is possible with the hand saw.

bedding of passengers — those portions of it which are not regularly laundered — blankets, mattresses and pillows, saying they should be freely exposed to the air and, if possible, to the sunshine after each trip. The somewhat common usage on inland steamboats of having the dining room on a deck below the water-line was not to be commended. Such a position renders proper cleanliness and ventilation more difficult, and

This saw has been used by me at the Throat Department during the larger part of last winter, and has given very good results. It was made for me by Codman & Shurtleff.

Reports of Societies.

AMERICAN PUBLIC HEALTH ASSOCIATION.
TWENTY-FIFTH ANNUAL MEETING, HELD IN PHILADELPHIA, OCTOBER 26-29, 1897.

FIRST DAY. — MORNING SESSION.

THE Association met at Hotel Walton, and was called to order by the President, DR. HENRY B. HORLBECK, of Charleston, S. C.

After the transaction of some routine business, the reading of reports and papers was begun.

REPORT OF COMMITTEE ON STEAMSHIP AND STEAM-BOAT SANITATION.

This was read by DR. FREDERICK MONTIZAMBERT, General Superintendent of Quarantine of the Dominion of Canada, in which he directed attention to the

tends to unwholesomeness. Reference was made to the all-important matter of the exposure of the traveling public on steamboats, as elsewhere, to the danger of contracting diseases from fellow-travellers suffering with consumption, who, in their expectorations, scatter infectious material broadcast. Objectionable and indefensible as it is at all times, with steamboat saloons closed and artificially heated the expectorator's filthy habit becomes especially dangerous to other passengers. The sputa drying on the decks rises as dust, to be inhaled, and to add to the great list of the victims of this fell destroyer of mankind. All spittoons should contain water or a disinfectant, which should be frequently changed. With the advancing education of the general public in the knowledge and belief in the contagiousness of consumption, and the methods to be employed to limit and prevent its spread, an ever-increasing degree of success may be confidently hoped for.

DR. EDUARDO LICEAGA, President of the Supreme Board of Health of Mexico, sent a paper entitled

A STUDY OF YELLOW FEVER FROM A MEDICO-GEOGRAPHICAL POINT OF VIEW,

which was read by Dr. Gihon, in the absence of the author.

The author said in part that in the port of Vera Cruz, which, as had already been shown, could be considered one of the sources in which the yellow-fever germ obtains a spontaneous growth, yet only three cases of the disease have appeared during the period under study, and these three cases occurred within the month of June. With respect to other points on the Gulf Coast, and especially the ports, it could safely be asserted that during the period covered by this report not a single case of yellow fever had presented itself.

Passing to the Pacific Coast, and bearing in mind the terrible epidemic that in the year 1884 desolated the coast, the Supreme Board of Health of Mexico had taken especial care to prevent the disease from being imported from the Central American countries, where unfortunately it now prevails in an epidemic form. Difficulties were still encountered in making an exact diagnosis between yellow fever and certain forms of paludic infection that in hot countries assume a very similar aspect and the serious character that is generally borne by that disease, so much so that even persons who are accustomed to observe the two affections are often uncertain as to the diagnosis. These doubts, the speaker hoped, would be dissipated in the future by the discovery of the yellow-fever microbe by Sanarelli. A knowledge of the cause of the disease will not only allow us to make an exact diagnosis, but will doubtless facilitate the means for attacking it in a certain manner.

DR. SAMUEL H. DURGIN, of Boston, spoke of the importance of closer and more careful bacteriological work in the study of yellow fever.

THE DRAINAGE, PLUMBING AND VENTILATION OF PUBLIC AND PRIVATE BUILDINGS.

A paper on this subject was read by MR. J. W. HUGHES, of Montreal.

The author confined himself to the ventilation of the plumbing system of a building, or, more correctly, that part of a plumbing system which serves for the conveyance of the house wastes known as sewage, and that are to be finally disposed of, as far as any particular building is concerned, when they reach the public sewer. It was no more possible to lay down rules covering every possible contingency called for in scientific plumbing and ventilating than it was to apply fixed rules to the practice of medicine. The principles of scientific medicine and plumbing were fixed, but the application of these principles called for the intelligence acquired by education and developed by practice. Much injury had been done by attempting to frame plumbing by-laws which would apply to every case. If the Association would make a study of the general principles covering this question and embody them in a code having its endorsement, leaving the practical application of those principles to those whose special duty it is to apply them, much good would result.

FIRST DAY. — AFTERNOON SESSION.

DR. JOHN L. LEAL, Health Officer of Paterson, N. J., followed with a paper on the same subject, in which he emphasized three points bearing upon the question of ventilation: first, that every building intended for occupancy should have some special means of ventilation; second, that these means should be commensurate with the requirements of any particular building; third, that the more simple and uncompli-

cated the means used the more successful was likely to be their operation. The object of plumbing is, first, the immediate withdrawal from a building of certain waste products of life, the presence of which would prove detrimental to health; and, second, to prevent harm to the inmates of the said building arising from these products after removal, through the means of their removal. Not only were we threatened by the presence of these substances, but we were also threatened by certain dangers inherent in the best system at our disposal for ridding ourselves of them.

REPORT OF THE COMMITTEE ON CAR SANITATION, by Prof. S. H. Woodbridge, of The Institute of Technology, Boston, was read by Dr. Durgin, in the absence of the author.

The author stated that something like interstate agitation and regulation were requisite to any legislative advancement in this field of hygienic improvement. For this reason it seemed the better way that the movement should originate within, or be fostered by, some strong railroad corporation which shall set the pace for other railroads to eventually put themselves in step with.

The writer described a new type of improved parlor and sleeping car which had been devised.

FIRST DAY. — EVENING SESSION.

At this session the public were invited. Prayer was offered by REV. WILLIAM N. MCVICKAR, D.D., of Philadelphia.

DR. BENJAMIN LEE, in the absence of Governor Hastings, welcomed the members and visitors on the part of the Commonwealth, and MAYOR WARWICK extended to them the hospitality of the city. The Mayor referred feelingly to the life-work of the late Dr. William H. Ford in the cause of municipal sanitation, after which the

ADDRESS OF PRESIDENT HORLBECK

was delivered.

Speaking of the progress made in the study of disease, President Horlbeck said that the theory based upon the humors of the blood had given place to a knowledge of the denizens of the blood, which were being recognized as surely as the flora and fauna of our fields. The microscope gave us the keynotes of our temporal welfare.

He then gave a history of the Association from its organization, in 1872, which he said had grown until there were now 1,844 names enrolled in its membership. During its existence some of the most important discoveries in the domain of medicine and surgery had been made, and the science of bacteriology had had its birth and development. Since the last annual meeting in Buffalo the method of diagnosing typhoid fever, as discovered and described by Vidal, of Paris, had been elucidated by Dr. Wyatt Johnston, of Montreal.

During the twenty-five years of the life of the Association the processes of taking care of contagious diseases had entirely changed. It was now an essential feature of practice in all communities to confine all such cases to the individual affected. He next dwelt upon the necessity for a pure water-supply, and then passed on to the consideration of quarantine methods. He recommended a government commission on yellow fever. It is estimated that over 95 per cent. of all the yellow-fever cases that had reached our shores had

come from Havana. A committee of the Association had been appointed to bring the vital question before the government of this country, and urge the governments of the countries interested to prompt action in this matter. This would seem to be the occasion when not only the recommendations of the committee on yellow fever should be carried out, but that the Association should make a demand on our general government to the effect that a commission of expert bacteriologists be sent to Havana and Rio, and be kept there until the *materies morbi* have been discovered, until the secrets of this dread disease have been unfolded. The examples of other countries in the solution of the problems involved in cholera, tuberculosis, bubonic plague and leprosy were noted; and why should we not solve the problems of yellow fever? He recommended that a committee from the Association be appointed to wait upon the President of the United States to carry out this idea.

Finally, reference was made to the experiments carried on by the State Board of Health of Massachusetts at Lawrence on the utility of filtration of water-supply with reference to the removal of typhoid germs, the average result being the removal of 98½ per cent. of the germs. A diminution of 60 per cent. in typhoid cases at Lawrence had been the result of sand filtration.

SECOND DAY.—MORNING SESSION.

DR. CHARLES SMART, of Washington, D. C., read the

REPORT OF THE COMMITTEE ON POLLUTION OF WATER-SUPPLIES.

The report stated that the committee had been chiefly engaged in perfecting the stand and methods of bacteriological research. The committee feels that it should be discharged from its duties, and that a new one should be appointed, which shall consist of a couple of men who are practically acquainted with municipal water-supplies, a couple more who know effectively the chemical aspects of the subject, and finally a like number who know as it should be known the bacteriology of the subject. The committee had, however, announced the bacteriological formulæ for use in laboratories.

In accordance with the suggestion the committee was discharged.

PROF. FRANKLIN C. ROBINSON, of Maine, spoke on the subject of

DISINFECTANTS.

He said he could not help noting how rapidly the knowledge and use of formaldehyd had spread. Only one year ago it was practically unknown in the United States. There was no apparatus for generating it in quantity except the one that was exhibited then. Now probably most, if not all, of the members had used it. He ventured to predict that we were far from knowing all about it, and that a year from now greater progress would be seen than during the past year.

DR. E. A. DE SCHWEINITZ, of Washington, D. C., followed with a paper on

THE DETERMINATION OF THE AMOUNT OF FORMALDEHYD YIELDED BY THE FORMALDEHYD LAMP.

PROF. S. BURRAGE, of Lafayette, Indiana, made some remarks on fumigation experiments with formaldehyd.

DR. FRANK W. WRIGHT, of New Haven, read a paper entitled

DIAGNOSIS OF SMALL-POX.

He said an early diagnosis of small-pox was of great importance. Next to vaccination this is the most essential factor in preventing the disease from spreading. If all cases of small-pox were typical, it would not be difficult to make a correct diagnosis; but in these days of general vaccination typical small-pox is seldom seen, the great majority of the attacks being modified by former vaccinia and commonly spoken of as varioloid; but we will call them modified small-pox. If by chance a health-officer should fail to recognize a case of small-pox and the disease should spread, he would be subjected to very severe criticism and would likely be removed from his position in disgrace. On the other hand, if he should declare some disease that resembles modified small-pox as that disease and future events prove that a mistake had been made, he would be just as severely criticised, and would probably have to defend himself in a suit for damages.

SECOND DAY.—AFTERNOON SESSION.

DR. A. WALTER SUITER, of Herkimer, N. Y., read a paper entitled

THE BARBER SHOP AS A MENACE TO THE PUBLIC HEALTH.

It seems that the time has arrived when the attention of public health authorities should be called to that part of hygiene which applies to the barber shop. The first attempt of modern times to regulate sanitarily the operations of the barber shop was recently made in the city of Paris. As a public regulation and by direction of the sanitary authorities an order has been promulgated requiring that specific rules of asepsis and disinfection shall be observed in all shops for the protection of the public.

One evening, several years ago, a sheepish-looking individual shuffled his way into the author's waiting-room and requested a prescription. He was observed to be suffering from disease and presented a most unattractive appearance; his face was literally covered with eruptions and his mouth and lips were ulcerous in high degree with mucous patches. The man's case was disposed of, and he was gladly dismissed. Having to take an early train, Dr. Suiter shortly afterward proceeded to the barber shop to prepare for his toilet. His barber's chair was occupied and he sat down to await his call. As the occupant was about to arise he was startled to observe the very patient for whom he had prescribed an hour before. It is needless to say that he took his departure. Then and there he resolved that his face should never again be shaved by a barber.

PROF. LEONARD PEARSON, of Philadelphia, discussed the subject of

MEAT INSPECTION.

Reference was first made to the amount of meat consumed by the various peoples of the world and to the methods of inspection followed in Europe and America. Since the bacterial origin of many diseases has been demonstrated, and the close relationship of many of the diseases of man and animals has been established, the importance of rational meat inspection has been greatly emphasized.

DR. EDWARD JACKSON, of Philadelphia, spoke of eye-strain from poor window-glass, and said the bad influence of defective window-glass was intensified by the eye having to look through different parts, causing different kinds of strain, so that the eye could not adjust itself so as to work with the best advantage. Even if the defects in the glass are comparatively slight, at a certain distance they will cause serious strain, similar to that of astigmatism.

DR. E. P. LACHAPPELLE, of Montreal, followed with the

REPORT OF THE COMMITTEE ON TRANSPORTATION OF DISEASED TISSUE BY MAIL,

in which he said that the postal authorities of Canada had lately given their consent to the use of the mails for this purpose, this result being largely due to the valuable help received from the newly appointed deputy postmaster-general, who, being a physician, was quite *au fait* as to the importance of the demand. As regards the United States, it may be said that since the use of the mails have been granted, the State Board of Health, of New Jersey, at least, which has fully availed itself of the privilege, has not detected any case of infection traced to the circulation through the mails.

THIRD DAY. — MORNING SESSION.

THE REPORT OF THE COMMITTEE ON HEALTH LEGISLATION

contained a proposed bill to establish a Department of Public Health, the latter to be under the control and management of a Commissioner of Public Health, who shall be a regularly educated physician, appointed by the President of the United States, and whose term of office shall be six years.

SURGEON-GENERAL GEORGE M. STERNBERG, of Washington, talked on the

BACILLUS OF YELLOW FEVER.

DR. J. E. MONJARAS, of San Luis Potosi, Mexico, spoke on

THE NECESSITY FOR ADOPTING AN INTERNATIONAL CLASSIFICATION OF THE PROFESSIONS.

DR. PETER H. BRYCE, of Toronto, read a paper in which he emphasized the view that in dealing with

TUBERCULOSIS

it is the duty of the State to do whatever can be done so well by the individual.

DR. SAMUEL W. ABBOTT, of Wakefield, Mass., followed with a paper on

CONSUMPTION AS AN INDOOR DISEASE,

saying that no form of infection had been studied with greater interest during the past quarter of a century than that of tuberculosis. As proofs that consumption is an indoor disease, he first called attention to the evidence shown by occupations, and secondly, to evidence presented by the conditions of age and sex.

At the close of the morning session the members visited the Medico-Chirurgical College and Hospital of Philadelphia, where they were entertained at a luncheon, and were afforded an opportunity of inspecting the splendid new amphitheatre and the various appointments of the institution.

THIRD DAY. — AFTERNOON SESSION.

This session opened with the reading of a paper by DR. S. A. KNOPP, of New York, on

THE URGENT NEED OF SANATORIA FOR THE CONSUMPTIVE, POOR OF LARGE CITIES.

The question what to do with the thousands of tuberculous patients who inhabit the tenement districts of our large cities, unconsciously disseminating the germs of their diseases among their own kin, friends and neighbors, or who crowd the wards of our general hospitals to the detriment and danger of the patients suffering from acute diseases, has become for the sanitarian one of the vital issues of the day. A number of well-known sanitarians were quoted as expressing the belief that the only solution of the question is the erection of special sanitariums under municipal control.

Two other papers were read on the subject of consumption. One dealt with bovine tuberculosis in its relation to the public health, and the other with tuberculosis and our milk-supply.

DR. LAWRENCE L. FLICK, of Philadelphia, in discussing the papers, said that no hope of accomplishing great results could be looked for until the public was educated on the subject of the infectiousness of the disease. This education was going on, and in Philadelphia in the last ten years there had been a reduction of the disease by one-third.

DR. LYDIA RABINOWITSCH, of Philadelphia, told of the experiments which she had made in the past two years with butter and milk. In milk she had found from 20 to 30 per cent. of tubercle bacilli. In 18 samples of butter from different stores she had not found the bacillus of tuberculosis, but a micro-organism which very much resembled it.

DR. E. F. STEWART, of East Orange, N. J., presented a paper entitled

A PLAN OF PURIFYING WATER.

MR. F. H. NEWELL, of Washington, D. C., followed with a paper on

INVESTIGATIONS OF WATER-SUPPLY BY THE UNITED STATES GEOLOGICAL SURVEY.

He said it had been demonstrated again and again that purification of sewage by filtration or by irrigation was practicable and could be conducted at reasonable expenditure, and it was to be hoped that the time was rapidly approaching when public sentiment would be aroused to the degree of compelling such filtration whenever public health or comfort were imperilled.

H. W. CLARK, chemist in charge of the Lawrence Experiment Station, gave

A BRIEF REVIEW OF THE WORK OF SAND FILTERS IN LAWRENCE, MASS.

In 1887 the deaths from typhoid fever at Lawrence were 12 per 10,000; in 1889, 18.75; in 1890, 13.33; in 1891, 12.20, and in 1892, 11.11. During 1893 the filter was built, and hence during a portion of the year filtered water was being used. In 1894 filtered water was in use during the entire year, and the death-rate from typhoid fever was 5 per 10,000; during 1895 it was 3.07; during 1896, 1.86, and the rate for the present year promises to be exactly the same as for 1896.

FOURTH DAY. — MORNING SESSION.

MR. RUDOLPH HERING, C. E., of New York, read
THE REPORT OF THE COMMITTEE ON DISPOSAL OF
GARBAGE AND REFUSE.

The report stated that it was expedient to make original researches, and the work of the committee had been confined to the collection of statistics and the inspection of plants.

A REPORT OF THE COMMITTEE ON THE TRANSPORTATION AND DISPOSAL OF THE DEAD,

was read by DR. CHARLES O. PROBST, of Ohio.

Among other things this report favored the preparation of bodies for shipment by "licensed embalmers."

DR. HENRY MITCHELL, of Asbury Park, objected to this on the ground that it sought to create a special class of workers, to whom all the business would be restricted.

Several other papers were read and discussed.

The following officers were elected for the ensuing year: President, Dr. Charles A. Lindsley, of New Haven, Conn.; First Vice-President, Dr. Benjamin Lee, of Philadelphia; Second Vice-President, Dr. John C. Schrader, of Iowa City, Io.; Secretary, Dr. Charles O. Probst, of Columbus, O.; Treasurer, Dr. Henry D. Holton, of Brattleboro, Vt.

The Association will hold its next meeting in Ottawa, Canada, 1898.

Recent Literature.

Pathological Technique. By FRANK BURR MALLORY, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School; Assistant Pathologist to the Boston City Hospital; Pathologist to the Children's Hospital and to the Carney Hospital; and JAMES HOMER WRIGHT, A.M., M.D., Director of the Laboratory of the Massachusetts General Hospital; Instructor in Pathology, Harvard University Medical School. Philadelphia: W. B. Saunders. 1897.

This work, as its title states, is devoted entirely to the methods of pathological examination. It is especially designed for practical use in the laboratory and by the general practitioner. Only those methods are given which have been tried and found satisfactory by the test of everyday use. Great attention is given to details, and the individual steps of each method are clearly and fully described. In fact, it would be hard to go astray in any examination if the directions given were carefully followed. The work cannot but prove indispensable to the student, invaluable to the practitioner and most useful to the specialist.

The arrangement of the book is novel, being based on the fact that the study of the pathology of disease only begins with the post-mortem, and is not complete without bacteriological and histological examinations. On this basis three main divisions are made: post-mortem examinations, bacteriological examinations and histological methods.

The steps of post-mortem examinations, both in hospitals and private houses, are fully detailed, and the points to be especially noted emphasized.

The division on bacteriological examinations is uniformly good. The section on clinical bacteriology will prove extremely useful to the clinician. The

preparation of media is described in detail as well as the usual bacteriological methods. The almost universal applicability of blood serum as a culture medium is emphasized and the authors' own rapid method of preparation and new "blood-serum coagulator" described.

In the division treating of histological methods the various methods of hardening and cutting tissues and the special usefulness of each are described. The preparation and use of stains, as well as the principles of their action, are fully gone into. Among the original methods are those for actinomyces in sections, ameba coli, neuroglia fibres and elastic fibres. The section on examination of the blood has many practical hints, and that on clinical pathology is excellent.

On the whole the book reflects credit on the progress of medicine in Boston, and is worthy to rank with the other works recently published by the teachers of the Harvard Medical School.

The Living Substance as Such and as Organism. By GWENDOLEN FOULKE ANDREWS. 8vo, pp. 176. Boston: Ginn & Company. 1897.

This beautifully printed work is issued as a supplement to the *Journal of Morphology*, and is, we believe, the first unscientific article issued by that valuable journal. It does not report any definite original observations of the authoress, although she informs us that the work was "assisted by exceptionally far-sighted eyes, having great range and swiftness of accommodation." Although the structure of protoplasm has been the topic of numerous painstaking researches by some of the ablest of living investigators — a recent review by Von Erlanger enumerates 53 new researches published on this subject within two years — our authoress considers it unnecessary to make any allusion to any of these writers, except Bütschli, whose foam theory she adopts, and of Bütschli she cites no articles. As regards the general ideas in the article we have found nothing sufficiently new and important to deserve even passing notice.

The authoress's language is, however, very original, and at times striking and picturesque. She has apparently taken George Meredith as her chief model, and her rhetorical terms are steadily surprising. On page 72 she says: "Pellicles open almost everywhere, and under very adverse physical conditions, as one would think. The interalveolar substance seems to be irrepressible." And this is a description of an observation! It is all there is at this point, the animal, the tissue, the cell, the part of the cell; the conditions at the time are left to the reader's imagination. The whole essay is in this manner. But the tone is of one infallible, and speaking *ex cathedra*. Professor Leidy described the unicellular Rhabdiodiophrys, individuals of which coalesce with others to form a wandering colony; whatever the number of individuals coalesced, pseudo podia are formed only at the periphery of the whole mass. That is clear and plain, but Mrs. Andrews's rhetorical longings are not so easily satisfied; and she paraphrases it in several sentences, of which the first reads: "That is, each Rhabdiodiophrys lays aside for the term of its union with the others the habit of close formation at all those portions of its mass, which, though still peripheral to itself, are not peripheral to the colony as such," etc. This is not thought, it is verbiage; and the proper recompense for the publication is oblivion.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 18, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

A NEW METHOD FOR THE RADICAL CURE OF INGUINAL HERNIA.

Of the invention of new methods for the radical cure of inguinal hernia there seems to be no end, and the constant occupation of surgical ingenuity upon this subject may be taken as an indication that no perfectly satisfactory method has so far been devised.

The latest contribution in the way of a new method of operating comes from Dr. George Ryerson Fowler, Professor of Surgery in the New York Polyclinic, who, in an instructive and well-illustrated article published in the *Annals of Surgery* for November, 1897, argues that the methods of operation now in vogue, namely, those which bear the name of Bassini, with its modifications devised by Halsted and others, leave a weak spot in the abdominal wall at the internal ring, owing to the funnel-shaped protrusion of the ligatured sac, and the emergence of the cord at this point, which invite the recurrence of the hernia.

McEwen's method of avoiding this defect, by fixing the folded sac under the internal ring, Fowler criticises as difficult to execute satisfactorily. Kocher's method of drawing the displaced sac outward through an opening in the aponeurosis of the external oblique toward the anterior spine of the ilium, and attempting to close the canal without incising its anterior wall, is only applicable in cases without pathological alterations of the sac, and is mechanically a faulty method. Attempts to modify Halsted's operation, by directing the cord upward and outward for a short distance on its emergence from the abdominal wall and fixing it by sutures, have proved unsuccessful, as the weight of the testicle soon proved sufficient to drag the cord down into its normal direction.

As a result of recent experiences in which herniæ have recurred in adults after operations which followed the essential feature of the Bassini operation, namely, the displacement of the cord directly forward through the internal ring and muscular parietes, Fowler has devised a method the essential feature of which

consists of an intra-peritoneal, or backward displacement of the spermatic cord, allowing the complete closure of the internal ring by sutures. The essential features of the operation are the following: (1) a curved incision of the skin, allowing a flap to be turned upward and exposing the canal, the anterior wall of which is incised; (2) separation and isolation of the sac and cord; (3) cutting away the sac at the level of the abdominal wall; (4) isolation of the deep epigastric artery and vein, and their division between ligatures; (5) incision of the posterior wall of the canal, including the transversalis fascia and peritoneum, upon the finger inserted through the neck of the sac. The operation is then completed by placing the spermatic cord within the peritoneal cavity, and uniting the transversalis fascia and peritoneum by broad approximation sutures in front of it until the lower end of the gap in the posterior wall of the original inguinal canal is almost reached. The cord is then brought forward through the newly formed external ring.

The canal is now closed by sutures of kangaroo tendon which include the conjoined tendon and the aponeurosis of the external oblique upon the inner margin, and Poupart's ligament upon the outer, and the new point of emergence of the cord is strengthened by the displacement outward of the pubic attachment of the corresponding rectus muscle.

Fowler commends his method as the only one which allows obliteration of the internal ring and inguinal canal, and has employed it in six cases, which, however, are of too recent date to allow of any estimate of permanent results. Although this method has certain features to commend it, the simpler operations of Bassini and Halsted with their modifications have of recent years met with such pronounced success that there can be no doubt of their efficiency in a large proportion of cases, and in those which present no extraordinary difficulties, there would seem to be no reason for discarding them for a method which is complicated by the additional steps of tying the deep epigastric artery and making an extensive incision into the peritoneum.

The conditions presented to the operator by different cases of hernia vary so greatly that no one method can promise success in every case. Experience may prove that in certain cases of large and long-existing herniæ in adults in which the whole posterior wall of the inguinal is stretched and protruded forward, and in which there is marked stretching and atrophy of the muscular and aponeurotic structures, Fowler's method will have distinct value.

The operation is certainly ingenious, and is devised to meet certain well-known faults of the older procedures as applied to this class of cases.

Up to the present time no perfectly satisfactory method of disposing of the cord in these cases without the extremely undesirable alternative of castration has been devised. If Dr. Fowler's method shall prove to have solved this problem, it will have very definite value.

THE MICHIGAN MONTHLY BULLETIN OF VITAL STATISTICS.

THIS monthly bulletin forms a new and commendable departure in medical journalism, inaugurated under the provisions of a recent statute of Michigan, which requires the issue of monthly bulletins, "showing the mortality of the State in detail, the prevalence of important causes of death, and such other information as shall be of public interest and sanitary value."

The State of Michigan has for many years had a system of registration of vital statistics, the value of which was much impaired by the fact that the returns were defective, a very considerable portion of the population not being embraced in the reporting districts. But as a result of the commendable zeal and progressive spirit of the medical officer in charge of this department (Dr. Wilbur) legislation has recently been secured which will undoubtedly place Michigan in line with the New England States so far as the efficiency and completeness of registration are concerned.

By this first report, for the month of September, 1897, it appears that returns of death were received from a total population of 2,061,616, which is 93.4 per cent. of the total population of the State. A small portion of the population living in sparsely settled districts and amounting to 33,000 persons is exempt from the operation of the new law. The total number of deaths in the registering population was 2,370, which is equivalent to an annual death-rate of 13.4 per 1,000. The deaths under one year were 603, and those from the principal infectious diseases were as follows: from consumption, 201; typhoid fever, 51; scarlet fever, 8; diphtheria and croup, 45; pneumoëmia, 57; diarrheal diseases (under five years), 432; cerebro-spinal meningitis, 25.

These returns appear to indicate, as a result of the operation of the new law, an increase in accuracy of the registration, amounting to 50 per cent. over the preceding years, as well as an increase in the promptness of the returns, and of their early publication.

The *Bulletin* furnishes valuable suggestions to the registering officials of cities and towns, and proposes an organization of the registrars of vital statistics throughout the country, with the view of adopting uniform methods of classification, and the estimations of populations and of death-rates.

MEDICAL NOTES.

A COLORED WOMAN PHYSICIAN.—A colored woman physician, a graduate of the Woman's Medical College in Philadelphia, recently applied for a license to practise medicine at Atlanta, Ga.

SUSPENSION OF A HOUSE PHYSICIAN AT BELLEVUE.—A member of the house staff of Bellevue Hospital, New York, has been suspended, pending the investigation of the charge of kissing one of the nurses in that institution.

IMPROVEMENT IN THE YELLOW FEVER SITUATION.—The occurrence of more or less severe and extensive frosts has put a new face upon the yellow fever situation, and the quarantines are being gradually abolished, greatly to the relief of trade.

YELLOW FEVER AND PHYSICIANS.—Several young practitioners have been stricken with the prevailing fever. Fortunately we have no fatality to record for October. Drs. J. Barnett, M. J. Magruder, H. Olliphant, Otto Lerch, E. P. Lowe, C. J. Miller, S. G. Kreeger are among those who have been attacked, but we are happy to state that they have all made good recoveries. — *New Orleans Medical and Surgical Journal*.

THE ANNUAL ADDRESS BEFORE THE CHICAGO PATHOLOGICAL SOCIETY will be delivered on the evening of Friday, December 3d, by George M. Sternberg, M.D., Surgeon-General of the United States Army. The subject of the address will be "Yellow Fever, its Etiology and Pathology."

HYSTERICAL LEGISLATION.—Hysterical is the adjective which fits such legislation or attempted legislation as we hear of in Georgia, where the House of Representatives has passed a bill making it a misdemeanor to engage in a game of football where matches have been arranged or gate money demanded.

FOOT-BALL NOTES.—The City Government of Chicago has refused to prohibit the game of foot-ball within the city limits by a vote of 56 to 7. President Fetterhoff, of Girard College, Philadelphia, has forbidden foot-ball playing by the students of that institution owing to one of the students having recently broken his leg in a practice game. The death of a boy named Bucknam, of Stoneham, Mass. from injuries received during a game of foot-ball has been recently reported.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, November 17, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 46, scarlatina 29, measles 9, typhoid fever 15.

A MEETING IN AID OF NEGRO EDUCATION.—There will be a Sunday evening meeting in the Old South Church, Boston, December 5th, in the interest of Negro Education as carried on at the Tuskegee Institute in Alabama. The Principal, Booker T. Washington, and other prominent persons will deliver addresses.

DEATH AT AN ADVANCED AGE.—Mrs. Mary Hollister Pitkin died November 14th, in Amherst, aged ninety-nine. She was one of the oldest persons in western Massachusetts and was the fourth person over ninety years old who has died in Amherst this year. Mrs. Pitkin was born in South Manchester, Conn., August 30, 1798. Mrs. Pitkin's father served in the Revolutionary War as a soldier and was with General Washington at Valley Forge.

SUFFOLK DISTRICT MEDICAL SOCIETY.—At a stated meeting of this Society, on October 30th, the President, Dr. Francis H. Brown, appointed the secretaries of sections as follows: Section in Clinical Medicine and Hygiene, Dr. E. W. Taylor; Section in Obstetrics and Diseases of Women, Dr. C. H. Hare; Section in Surgery, Dr. Paul Thorndike. A committee for preparing a list of candidates for officers of the Society was also chosen, consisting of Drs. J. Collins Warren, G. W. Gay, F. W. Draper, S. H. Durgin, J. H. McCollom.

NEW YORK.

INSANITY NOT INCREASING.—The report of the State Commission in Lunacy for the year ending September 30, 1897, for the first time shows a decrease in the number of original commitments to the State Hospitals for the insane. The apparent increase in insanity indicated by their previous reports would seem to be probably due to the fact that during the period since these hospitals have been established many insane persons have been committed to their care who were previously neglected or cared for in private.

COMPLETE AND UNIVERSAL ANESTHESIA.—Dr. Charles E. Nammach recently presented to the Neurological Section of the New York Academy of Medicine a case of complete and universal anesthesia, in the person of a young woman twenty one years old, which is believed to be unique. The anesthesia is constant, not simply present when she is hypnotized, but so sensitive is the patient to hypnosis that she can be readily thrown into a state of profound catalepsy by a glance of the eye or at the hypnotic suggestion of any one.

APPENDICITIS DELAYS A TRIAL.—A new sensation has been created in the sensational Guldensuppe murder case by the seizure, on the third day of the trial of Martin Thorn for the crime, of one of the jurors with appendicitis, rendering necessary an operation on the following day, the dismissal of the other jurors, and a new trial altogether. The incident will probably be regarded also as an illustration of the prominence which appendicitis would seem to have attained as a factor in modern life.

THE NEED OF THE PROPOSED DEPARTMENT OF PUBLIC HEALTH.—The New York Board of Trade and Transportation, at a meeting held November 10th, adopted a resolution declaring the health of the people of far more importance than the proposed enlargement of the navy or other preparations for war, and calling for the appointment of a committee to consider the desirability of the establishment of a national department of public health.

THE AMERICAN ORNITHOLOGICAL UNION.—The fifteenth annual meeting of the American Ornithological Union was held last week at the American Museum of Natural History, on Manhattan Square, and there were more than a hundred delegates present. Dr. C. Hart Merriam, of the Department of Agriculture, Washington, presided at the sessions, and among

those in attendance were Drs. Elliott Coues, of the Smithsonian Institute, Jonathan Dwight, Walter Saxon, of Cambridge, Mass., and Albert K. Fisher, of the Department of Agriculture.

THE GROWTH OF COLUMBIA UNIVERSITY.—There are this autumn enrolled in the various departments of Columbia University 2,017 students, a gain of about 250 over last year. This is the highest number ever reached, and it is expected that by Christmas it will be increased to 2,150.

AN ANTHROPOMETRICAL BUREAU.—In order to maintain the physical condition of the men on the force in the greatest efficiency possible the Board of Police have established an Anthropometrical Bureau. All applicants for positions as policemen have been required to pass a rigorous physical examination, but after they have once been admitted to the force little or nothing has hitherto been done to keep the men in good condition. The new bureau will have charge of the matter and will see that gymnastic apparatus and other appliances are placed in the various station-houses. At its head will be Dr. A. H. Brown, an expert on physical training, who during the last three years has passed on the condition of more than ten thousand applicants. For this purpose he has been transferred from the Civil Service Commission to the position of police surgeon. The Anthropometrical Bureau is also to have charge of the measurement of criminals by the Bertillon system, which has up to the present time been conducted by the detective department.

THE FORCE OF HABIT.—The force of habit is strikingly shown in the case of the foreman of one of the city engine companies, who, while on duty at a fire, received a bad fracture of the ankle, and was admitted to the Manhattan Hospital for treatment. One night shortly after the accident a gong in the hospital struck one of the numbers to which his company was accustomed to respond, and being suddenly awakened from sleep by the sound, he sprang from his cot to the floor with such force as to cause another fracture.

NEW PARKS RECOMMENDED.—The advisory committee appointed by Mayor Strong has handed in a report in which is recommended the opening of a number of small parks and children's playgrounds. Fourteen new sites in crowded sections of the city are recommended, two of which, the mayor states, will be acted on at once; the rest as soon as practicable. The report compliments the Dock Department for providing recreation piers, and the Board of Education for opening out of school hours the playgrounds which are required by law in connection with all new school-houses. It also recommends the establishment of a park on Randall's Island, in the East River, as soon as the necessary legislation can be obtained.

A SUCCESSFUL SYMPHYSEOTOMY.—A symphyseotomy, with successful results, was performed at the Kings County Hospital, at Flatbush, on November 9th, by Dr. Robert L. Dickerson, of Brooklyn.

Miscellany.

TRAINED ATTENDANTS FOR CHRONIC CASES.

It is perhaps not generally known among physicians in Massachusetts that the Massachusetts Emergency and Hygiene Association maintains a Department of Instruction to Attendants, in which women are trained for the position of attendant in the care of convalescents, feeble or elderly persons, and subacute and chronic cases, and for other cases which do not require the skill of a trained nurse. These attendants are taught to take temperature, pulse, etc., make and change sick-beds, and perform the duties of a nurse where there is not great responsibility or where serious emergencies are not likely to arise. They are taught how to serve meals to the sick and how to prepare many articles of an invalid's diet. Attendants are intended for mild cases of sickness and chronic invalids and for other cases where a trained nurse cannot be afforded, to intelligently assist the family in caring for the sick.

Attendants receive for their services, during their first year after graduation, seven dollars a week, and after the first year may charge ten dollars a week, but never more than twelve dollars.

The course of study lasts but nine weeks, whereas a regular training-school requires two years; and it has been found that there are many persons who cannot afford to pay for a trained nurse, but can afford to pay the price an attendant charges; and there is at the Directories for Nurses a constant demand for persons occupying the position which the attendant, as trained by this Association, is intended to fill.

During their course of instruction the pupils are under the constant observation and instruction of a trained nurse, and it has been found that surprisingly good results are attained considering the brevity of the period of instruction. Those graduated last year have been nearly constantly employed; a good per cent. of those of earlier date have been well employed and many of them have been in the same place for years.

The diplomas of the Association permit the holders to register as attendants at the Directory for Nurses, 19 Boylston Place, Boston.

Pupils not wishing to become attendants and to be registered as such, can take the lectures and class work, and receive a special certificate for the work done.

The Association desires to find cases among the needy to which it can send its pupils to care for the sick and so gain for them the necessary experience and training. Physicians who know of cases suitable for the care of pupil attendants may obtain the services of pupils and thus benefit both their patients and the Department of Instruction, by applying to the instructor, Dr. Anna G. Richardson, for the services of a pupil attendant.

The following are the rules under which pupil attendants are furnished:

(1) The case must be suitable and the instructor must have a suitable attendant to send.

(2) The attendant can remain with the patient as long as necessary, except during the time of class work and a proper time for rest each day.

(3) This department is under the supervision of a

trained nurse, who must be allowed to visit the case at any time to direct and instruct the attendant.

(4) It must be understood by the attending physician that an attendant is not a trained nurse and cannot assume the responsibilities of one, but requires explicit directions.

MARRIAGE BY CAPTURE IN ARABIA.

EDWARD S. HOLDEN writes to *Science*, September 15, 1897:

"Antar" is a Bedouin romance reputed to have been written by Asmai, one of the learned men of the court of Haroun-al-Raschid, shortly before the beginning of the ninth century. From the translation by Terriek Hamilton (London, 8vo, 1820), Vol. iv, pp. 388-89, the following description of an early Arabian marriage custom is quoted. The custom is a well-known one. Asmai's explanation of it is new to me.

"Now, there was a certain curious custom current among the Arabs at that period. The night on which a bridegroom should wed his wife, they brought a quantity of camel pack-saddles and heaped them one upon another, decorating them with magnificent garments. Here they conducted the bride, and having seated her on high, they said to the bridegroom, 'Come on, now, for thy bride!' And the bridegroom rushed forward to carry her off, whilst the youths of the tribe, drawn up in line, right and left, with staves and stones in their hands, as soon as the bridegroom rushed forward, began beating and pelting him and doing their utmost to prevent his reaching his wife. If a rib or so were broken in the affair it was well for him; if he were killed it was his destiny.

"But should he reach his wife in safety, the people quitted him and no one attempted to approach him. 'I inquired about this circumstance,' says Asmai, 'and what it was they were about.' 'Asmai,' they answered, 'the meaning of this is to exhibit the bride to the warriors, that should her husband die, any one else might take a fancy to her and take her off.'")

So far as my reading goes, the explanation of marriage by simulated capture, which is given in the last sentence, is entirely novel.

LAYING OF THE CORNER-STONE OF BELLEVUE HOSPITAL MEDICAL COLLEGE.

THE corner-stone of the new buildings of the Bellevue Hospital Medical College, New York, was laid with appropriate ceremonies on Saturday afternoon, November 13th. They are situated on 26th Street, adjoining the Carnegie Laboratory and opposite Bellevue Hospital. It is expected that they will be completed in time for the opening of the next college session, and the cost of erection will be about \$200,000. The building committee consists of Dr. Edw. G. Janeway, President of the School, Dr. Austin Flint, Secretary, and Drs. H. M. Biggs and F. S. Dennis, members of the Faculty.

The exercises were presided over by Mr. D. O. Mills, President of the Board of Trustees, and the corner-stone was laid by the venerable Dr. Lewis A. Sayre, now Emeritus Professor of Orthopedic Surgery, who was the only representative present of the founders of the college. Among the deposits in the stone was a small package of antitoxin and a sealed glass tube of living specimens of the bacillus *aerogenes capsulatus* cultivated in the Carnegie Laboratory. Accompanying the latter was a written description stating that these were the oldest identified spores of this species of bacterium. Dr. Sayre in

his address gave the following interesting account of the origin of the college:

"One day I had an exceedingly interesting clinic, and the amphitheatre (Bellevue) was so crowded that there was not standing room in the aisles or gallery. After my clinic, while walking up 26th Street with Dr. Stephen Smith, who was then one of the surgeons of the hospital, he said to me that while the students attended the different colleges to get their diploma, or legal license to practise, yet they had to come to the Bellevue Hospital clinic to get the actual knowledge which enabled them to practise their profession. Dr. Smith then and there suggested that a medical school be formed in connection with the hospital, so that students could receive the advantage of more thorough practical teaching, instead of being limited to one hour's clinical instruction in a day. This was the first suggestion I ever heard of establishing a medical school in connection with Bellevue Hospital. Soon after this conversation the Commissioners of Charities and Correction requested Dr. Isaac E. Taylor and myself to go to Albany and secure a charter for a college to be connected with the hospital and empowered to grant medical degrees. This we did in April, 1861, and the Bellevue Medical College was thus founded—the object of the school being to combine practical clinical demonstration with didactic teaching, in accordance with its motto, *Clinica Clinice Demonstranda*. In 1885 the Carnegie Laboratory, devoted to bacteriological and scientific research, was given to the college by the generosity of Mr. Andrew Carnegie. This was the first institution of the kind connected with any medical college in this country. . . . Since its organization Bellevue has sent out 4,745 alumni, who can be found in almost all parts of the civilized globe, and last year had 715 matriculants."

The remaining exercises were held in the large lecture-room of the Carnegie, and Dr. Landon Carter Gray, President of the Alumni Association of the College, was the first speaker. In his address he made the following reference to the old Faculty: "Austin Flint, with his massive head and benign face, which was once compared to that of Fénelon; James R. Wood, the incomparable operator, eagle-eyed, rubicund of visage, spotlessly attired, even in the morning in his dress suit, which was invariably adorned with a buttonhole nosegay; Van Buren, grand of manner, with an easy flow of simple words, and his high head knocking the stars; Frank Hamilton, erect in his military bearing and precise in language; Fordyce Barker, husky of voice, but of strikingly commanding presence; Isaac E. Taylor, a tremendous man, as I recently heard him called; Sayre, now living in a ripe age, with the satisfaction that is rarely vouchsafed to a man of genius, of seeing his own original ideas universally accepted; and Austin Flint, the younger, whose lectures are to-day as lucid and charming as of yore."

The Rev. Roderick Terry, D.D., spoke briefly on the behalf of the Trustees of the College, and Dr. John S. Billings then made an address as the representative of the medical profession in general. In the course of it, he said: "It is now fifty years since the medical profession made an organized effort to improve medical tuition in this country. When I was a student we attended two courses of lectures which were just alike. There was no laboratory work, and there might not be any clinical work. The time has

long gone by when a lecturer was considered a sufficient equipment for a medical school. The lecture-room is becoming the least important part of the college. The clinic is what characterizes modern medical education.

MAN AND MEDICINE.

DR. J. F. GOODHART, one of the prominent London consultants, delivered, October 13th, the inaugural address at the opening of the York Medical Society.¹ It contains so much shrewd sense tempered by a liberal kindliness, and so much wisdom controlled by experience in regard to the relations between the laity and the medical profession, between the man in the street and the regenerate, as Dr. Goodhart puts it, that we commend the entire address to those of our readers who may have access to it. Others will thank us for the closing paragraphs:

Patients and medical men look upon their mutual relationship from different points of view. The man in the street in this instance takes a business view of his association with his adviser. He considers that the payment of the bill is the just equivalent, the *quid pro quo* that settles all claims—indeed, he has been known to think that the *quid* was more than the *quo* and to grumble thereat—and that he can henceforth try, if he is so minded, the latest fashion—the young man who has just come to town, and who is "so clever" (it is only the young that are "so clever"). But the medical man looks at things very differently. He feels, and rightly feels, if it be kept within due limits—but I think we are inclined to push it too far—that in the great majority of cases he undertakes responsibilities, undergoes sacrifices, and enters into delicate relationships by becoming in large measure a partner in other people's anxieties and sorrows as well as having to bear all his own, for the wear and tear of which no money payment is an equivalent. The only payment that we accept as payment *in full* is gratitude, and gratitude for imperderable service such as medicine renders to mankind is too often a stream with full head which rapidly gushes itself out. There is much truth as well as humor in "Gratitude is a lively expectation of favors to come." No medical man could be such and conduct his business on purely business principles. I will not claim for the profession of medicine that it is more righteous than any other calling in life, but I should always maintain that, however much the public might think and wish to have it otherwise, the larger half of the practice of medicine is, and must be, pure philanthropy. Not a case comes before one probably but that much more is done for it than ever the patient supposes. He supposes that he comes for an opinion and he gets it, and that that is the whole of the transaction. If that were all one had to do, medicine would be much simpler, perhaps, but it would be much less entralling. But before forming an opinion you probably have to throw yourself into the position in life of the patient, as far as possible, to realize yourself his hopes and his fears, his troubles here and his ties there, and numberless things that have nothing to do with the disease, but everything to do with the treatment and with your power to give the very best advice that the circumstances of the case admit of. And when you have come to an opinion, there is then again the necessity of entering into the man's feelings and shaping your words in accordance therewith. Thus at the end of any investigation the larger number of items in the bill cannot possibly be discharged by any equivalent in gold. You have been obliged, even though willingly, to become the friend and confidant of a family, and friendship and sympathy cannot be bought or sold. It is often said, "You doctors are hard men." I have even heard it said of the ladies who have taken to the practice of physic that they, too, upon occasion are not too conspicuous for the exhibi-

¹ Lancet, October 30th.

tion of sympathy. Well, a medical man cannot wear his heart upon his sleeve. I sometimes reply, "If you could but join us you would know that it is scarcely possible to be hard in the practice of medicine." The outsider knows nothing of the storms of anxiety, born entirely of sympathy, that sweep through the mind of the medical man when harassed by a critical case. Have I done the best possible thing? is present night and day, perhaps for many days together, upon such occasions, and the relief that is experienced when the sick one emerges from danger is so keen that it can only be compared to the feelings of the convalescent himself when he returns to the pleasure of living.

"Can naethin' be done, doctor? Ye savit Flora Cammil and young Burnbrae, an' yon shepherd's wife Dunleith wy' an' we were a' sae proud o' ye, an' pleased tae think that ye hed keepit deith frae anither hame. Can ye no think o' *somethin'* tae help Annie, and gie her back tae her man and bairnies?" and Tammas searched the doctor's face in the cold weird light.

"There's nae poorer in heaven or airth like Iuve,' Marget said to me afterwards. . . . 'Oor herts were as water afore Tammas's words, an' a' saw the doctor shake in his saddle. I never kent till that meenut hoo he had a share in a body's grief, an' carried the heaviest wecht o' a' the Glen. A' peeted him, wi' Tammas looking at him sae wistfully as if he had the keys o' life an' deith in his hands.'"

Thus there does grow up in the medical man's being a sense of a peculiarly close interest in the life that in God's good providence he has helped to steer through the quicksands of illness, and he comes to look upon his patients as in some sort his children, and to claim from them an allegiance in all matters pertaining to their health, which they at the most but very imperfectly recognize, and the binding nature of which they cannot therefore understand. But this relationship between men and their family practitioner is a very valuable one, and should be tenderly cherished. For I think there can be no doubt that the tendency in modern life is to change this old, and, as I think, salutary order of things. But, as I have already said, you may go to the great man in the town, but you still have a constitution or a temperament, of which you know little, and he may see nothing in one short interview. The three orders of medicine — medicine, surgery and general practice — are still as necessary as ever they were. You may do without the last-named when there is nothing the matter with you, you may go to the specialists in town for an opinion on an obscure case, or to settle a moot point in treatment; but when one is really ill, then it is that you want, and cannot do without, the man with the cheery voice, the kindly smile, the deft hand, the many-sidedness of resource for easing pain born of long experience in many fields, and with it all the ready self-sacrifice that at times like these makes the medical man almost seem to be "He that sticketh closer than a brother."

But I must stop. I have even now hardly more than indicated a few of the many points that my subject admitted of, but which were difficult to harmonize within the scope of the interest of an hour. Briefly put, my dominant idea is that man remains much too ignorant at the present day of the rudiments of the workings of his various parts. Thus it happens that at one time there is still a too blind faith in the power of the medical man, and at another time an equally blind intolerance and questioning of the restrictions and regulations that he, in his wisdom, feels called upon to impose. It would be much better for both parties concerned, and much more helpful to the art of healing, if medical man and patient could meet upon some common ground, and if the layman were able to follow the trains of thought that we may wish in some measure to make him understand, to realize in some small measure the great responsibility that medical men have to undertake. I do not suppose that this can be done to any great extent; in the case of the illness of those who are dear to us the issues involved are so tremendous to us that to think on anything, much more on unfamiliar lines, becomes well-nigh impossible. Nevertheless, we should be better off if everyone had learned in some slight fashion to think upon the

functions of their various parts and on the way in which those functions are conducted. There would then be less ignorance of the extreme intricacy of the subject; it would be more freely admitted that doubts must arise on all sides; and that watchfulness on the part of the medical man, and patience on the part of the sick man and of his relatives, are often the most important elements in successful treatment. The *Spectator* wrote the other day that "modern medicine discards more and more the old remedies of specific drugs, and relies more and more on the natural agencies, striving to reduce to a minimum artificial devices." And yet how much we see of the old order of things. The mass of mankind does not seem to me to have adequately kept up with this march of medical knowledge, and thus one is still too much in the seethe of excitement over the last new specific; the absolutely impossible is still deemed to be within the range of actual accomplishment; a medicine is still swallowed more as a charm than as a direct means to an end; and ignorance and shrewdness and the chances of life which happily mostly seem to make for health are together able to compete successfully with real knowledge. While this is so it can hardly be wondered at, life being so precious and tenacious as it is, that when common-sense advice is tendered it is too likely to be met in the same spirit as of old. "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? may I not wash in them, and be clean?" And the medical man, out of the depths of a yearning disappointment at the apparent hopelessness of his contest against the competing forces, is too often driven reproachfully to respond, "If the prophet had bid thee do some *great* thing, wouldest thou not have done it?"

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, NOVEMBER 6, 1887.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Deaths reported 3,427; under five years of age 750; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough,

erysipelas, and fevers) 302, acute lung diseases 326, consumption 305, diphtheria and croup 103, diarrheal diseases 89, typhoid fever 49, measles 18, scarlet fever 13, malarial fever 12, cerebro-spinal meningitis 9, whooping-cough 7, erysipelas 2.

From measles New York 13, Pittsburg 5. From scarlet fever New York 7, Chicago and Brooklyn 2 each, Baltimore and Salem 1 each. From malarial fever Brooklyn 5, Nashville 3, Baltimore 2, New York and Charleston 1 each. From cerebro-spinal meningitis New York 3, Cambridge 2, Baltimore, Boston, Worcester and Somerville 1 each. From whooping-cough Pittsburg 3, New York, Cambridge, Washington and North Adams 1 each. From erysipelas New York and Baltimore 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending October 30th, the death-rate was 17.6. Deaths reported 3,716, measles 117, diphtheria 98, fever 76, diarrhea 74, scarlet fever 55, whooping-cough 43.

The death-rates ranged from 9.5 in Cardiff to 25.7 in Wolverhampton; Birmingham 19.2, Bradford 12.0, Brighton 10.7, Gateshead 19.1, Hull 16.5, Leeds 16.0, Leicester 10.5, Liverpool 21.3, London 17.7, Manchester, 21.1, Newcastle-on-Tyne 19.9, Nottingham 14.1, Sheffield 22.2, Swansea 15.6.

METEOROLOGICAL RECORD

For the week ending November 6th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 6, 1897, TO NOVEMBER 12, 1897.

Leave of absence for one month is granted CAPTAIN ISAAC P. WARE, assistant surgeon, Fort Grant, Ariz.

Leave of absence for two months and twenty-six days, to take effect when, in the opinion of his department commander, his services can be spared, is granted MAJOR LOUIS W. CRAMPTON, surgeon, Fort Meade, S. D.

Leave of absence for two months, to take effect when his services can be spared, is granted CAPTAIN ROBERT S. WOODSON, assistant surgeon, Jackson Barracks, La.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 13, 1897.

JAMES R. WAGGENER, surgeon, relieved from the "Marion" and ordered to resume duties at Mare Island Navy Yard.

C. BIDDLE, surgeon, detached from duty at the Navy Department 12th inst., and ordered to the "Newport" 13th inst.

C. H. T. LOWNDES, passed assistant surgeon, detached from the Washington Navy Yard 12th inst., and ordered to the "Newport," 13th inst.

J. E. GARDNER, surgeon, detached from the "Dolphin" and ordered home on waiting orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING NOVEMBER 11, 1897.

WHEELER, W. A., surgeon. When relieved by Passed Assistant Surgeon W. P. McINTOSH, to rejoin station at Cincinnati, O. November 10, 1897. Granted leave of absence for one month from November 15, 1897. November 11, 1897.

WASDIN, EUGENE, passed assistant surgeon. Detailed by the President for special duty at Habana, Cuba, for bacteriological investigation of yellow fever. November 11, 1897.

McINTOSH, W. P., passed assistant surgeon. When relieved by Passed Assistant Surgeon G. B. YOUNG, to proceed to St. Louis, Mo., for temporary duty. November 10, 1897.

MAGRUDER, G. M., passed assistant surgeon. To resume command of Service at Galveston, Tex. November 10, 1897.

GUIERAS, G. M., passed assistant surgeon. To rejoin station at Key West, Fla., not later than November 20, 1897. November 11, 1897.

GEDDINGS, H. D., passed assistant surgeon. Detailed by the President for special duty at Habana, Cuba, for bacteriological investigation of yellow fever. November 11, 1897.

YOUNG, G. B., passed assistant surgeon. To resume command of Service at Memphis, Tenn. November 10, 1897.

NYDEGGER, J. A., passed assistant surgeon. To proceed to Brunswick Quarantine, Ga., for temporary duty, arriving there not later than November 30, 1897. November 10, 1897.

GREENE, J. B., assistant surgeon. Upon being relieved by Passed Assistant Surgeon G. M. GUIERAS, to report at Bureau preparatory to detail as medical officer of the Revenue Steamer "McCulloch." November 11, 1897.

RECENT DEATHS.

HARRISON ALLEN, M.D., emeritus professor of comparative anatomy in the Medical School of the University of Pennsylvania, died suddenly on November 14th. He was born in Philadelphia in 1841, graduated from the University of Pennsylvania in 1861, and soon after entered the regular army. He was stationed at Washington, and in 1865, at the age of twenty-four years, was called to the chair of comparative anatomy and zoology, which he held until May, 1895. He was the author of numerous monographs, papers and books in many departments of medicine and natural science. At the Columbian Exposition Dr. Allen was one of the judges on anthropology. He was president of the Pathological Society in 1877; president of the American Laryngological Association in 1886; president of the Association of American Anatomists from 1891 to 1893.

DR THOMAS W. EVANS, the famous American dentist, died suddenly at Paris, November 12th. He was born about 1823 in Philadelphia. His father was a soldier of the War of 1812.

Dr. Evans began the practice of dentistry in Lancaster, Pa., but, after a few years, having been called to Paris for a consultation, he established himself there and rapidly rose to the head of the dental profession in Europe. He was employed by the King of the Belgians, Louis Napoleon, and later by most of the royal families of Europe.

Sent by the Emperor during the Crimean War to study the sanitary condition of European camps and hospitals, he was so impressed by the misery and suffering there presented to him that on his return he secured the interest of the civilized world in important measures of reform. His record during the late Civil War in the United States will be found in the history of the United States Sanitary Commission, of which he was an active organizer in Philadelphia. During the Franco-Prussian War he was at the head of the ambulance service. His last service to the ill-fated Imperial family of France, was his co-operation in the removal in secret of the Empress to England out of Paris. Since the death of the Emperor he has been living in quiet retirement in Paris.

He is supposed to have left a very large fortune, a part of which, there is reason to believe, will be devoted to the founding and maintenance of educational institutions in this country.

BOOKS AND PAMPHLETS RECEIVED.

Vade Mecum of Ophthalmological Therapeutics. By Drs. Landolt and Gyax. Philadelphia: J. B. Lippincott Co. 1898.

Fifteenth Annual Report of the Trustees of the Soldiers' Home in Massachusetts, at Chelsea, for the year ending June 30, 1897.

A Text-Book of General Botany. By Carlton C. Curtis, A.M., Ph.D., Tutor in Botany in Columbia University. New York: Longmans, Green, & Co. 1897.

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Second series. Vol. II. B.—Lywater. Washington: Government Printing Office. 1897.

Text-Book of Materia Medica for Nurses. Compiled by Lavinia L. Dock, Graduate of Bellevue Training School for Nurses. Third edition, revised and enlarged. Eleventh thousand. New York: G. P. Putnam's Sons. 1897.

Comparative Frequency of Stone in the Bladder in the White and Negro Races. Acquired Umbilical Hernia in Adults. Value to the Public of State Medical Societies. Symptoms and Treatment of Hepatic Abscess, with Report of Seventeen Cases. By George Ben Johnston, M.D., Richmond, Va. Reprints. 1895-97.

THREE CASES OF EXTRA-DURAL ABSCESES; OPERATIONS AND RECOVERIES.

BY J. ORNE GREEN, M.D.,
Clinical Professor of Otolary in Harvard University.

CASE I. Fracture of the skull, infection and extra-dural abscess.

M. E., an unusually strong, healthy man, aged twenty-seven, about November 1, 1895, jumped from a rapidly-moving electric car, received a scalp wound over the left parietal bone, and was unconscious for a short time. The scalp wound was stitched at the time. Shortly after the accident there was bleeding from the left meatus, followed by a serous discharge for two or three days only. Two weeks after, he began to have pain in the ear; and at the end of another fortnight an edematous swelling appeared above the auricle and extended so far forwards as to close the left eye. There was no dizziness, no nausea and no headache, the pain consisting of occasional sharp shoots from the ear into the left temple. The tests were, W. L. c/100, V. L. 1/25 and Weber, localized in the affected side; by Valsalva's inflation there was no perforation whistle.

He entered the infirmary on December 15th. There was a diffuse swelling of the upper wall of the osseous meatus, and below this granulation tissue which completely concealed the deeper parts. The external swelling was entirely above the linea temporalis and zygoma; was edematous and extended forwards to the eye and upwards half-way to the vertex to the cicatrix of the original wound; it was most prominent two inches above the auricle, where a distinct crater with fluctuation could be felt. There was no sensitiveness of the mastoid. Under ether the swelling was incised freely at the crater, over the original cicatrix and over the temporal fossa; no collection of pus was found, but there was bare bone at the crater and in the temporal fossa. The three openings were connected by drainage-tubes and dressed daily with douching with sublimate 1-3,000, and the meatus was similarly treated.

December 21st. The bare bone had covered with granulations except one small spot at the crater; the ear was dry, and all swelling had disappeared; the drainage-tubes were removed and iodoform gauze substituted. All pain had ceased.

December 28th. A probe was found to enter a small carious hole in the bone at the position of the crater; under ether the bone was fully exposed, and two fractures of the temporal bone were seen, one beginning just above the zygoma, running upwards and backwards, and one from the squamous suture downwards and forwards; at the junction of the two was a

carious perforation three-sixteenths of an inch in diameter, filled with exuberant granulations from the dura. The opening was enlarged with rongeurs to nearly an inch in diameter, evacuating some three drachms of inodorous pus. The anterior edge of the fracture was depressed about one-sixteenth of an inch below the posterior edge, but attempts to raise it were futile; the upper fracture extended into the parietal bone but was not exposed, as a probe passed beneath the periosteum showed a perfectly smooth surface. The area of granulating dura did not extend beyond the opening in the bone, as was seen by pushing the dura inwards; the dura itself was pulsating distinctly. The granulations were not removed, the whole wound was douched with corrosive solution, 1-5,000, the upper portion sutured and the rest packed lightly with iodoform gauze. Convalescence was uninterrupted; the wound was septic, was dressed daily, then every second, then every third day. It gradually closed by granulation, and on February 26th was entirely healed. The inflammation of the ear was confined to the meatus, and was healed within a few days after the first operation. More than a year afterwards the patient was in perfect health.

CASE II. Infection of the tympanum, caries of the antrum-roof and extra-dural abscess.

J. H., a strong, healthy man, aged forty, from a cold in April, 1896, had earache, for which he applied at the infirmary, where a paracentesis was done, and the ear discharged purulent fluid for one week, and then the discharge ceased. The earache returned; another paracentesis was done; the discharge continued for about a week, then ceased from closure of the perforation. This history kept repeating itself: earache, complete relief from a paracentesis as long as the discharge continued; with closure of the perforation, gradual return of the pain. Between April 14th and November 1st, ten paracenteses were required.

On November 10th he began to have the old symptoms, five days from the cessation of the last discharge; the left membrana tympani was swollen and injected so that all landmarks had disappeared, but there was no localized bulging. He complained of pain in the ear and over the side of the head; there was no tenderness of the mastoid, but distinct sensitiveness over an area two inches in diameter on the squamous bone, just above the linea temporalis, and another sensitive spot two and a half inches upwards and backwards from the auricle over the parietal bone. A paracentesis evacuated a sero-purulent fluid, and a culture taken from within the tympanum showed infection with the staphylococcus aureus (Dr. Daley). The temperature was 99° F. Arguing that, from the history, there was some focus of inflammation not yet reached which was continually re-infecting the tympanum, I advised exploration of the mastoid.

November 13th the mastoid was opened; the cortex was not inflamed; the interior was partly pneumatic and partly hyperostosed, inflamed, but without any large collection of pus. The roof of the antrum was destroyed by caries, and about a drachm of pus was evacuated from between the dura and the squamous bone. The opening was enlarged upwards, exposing the dura for about half an inch, or as far as the pus seemed to extend. All carious bone was chipped away, the cavity cleansed by wiping and packed with iodoform gauze.

November 17th there was some oozing on the dress-

ing, which was changed; and on account of eczema of the auricle, sterile gauze was substituted for iodoform gauze.

November 18th the perforation of the drum-membrane had healed; the dural cavity was discharging slightly, and was dressed daily. It gradually filled up by granulations. All pain had been entirely relieved from the day of the operation, and the patient was about the ward, but a slight discharge continued from the dura.

On January 7th he again complained of pain in and about the ear, but without any return of pus in the tympanum; and at the spot of sensitiveness over the parietal bone, first noticed on his admission, was an area of edema about three-quarters of an inch in diameter. Under ether the tissues were incised, the periosteum reflected, and a fistula through the bone three-eighths of an inch in diameter exposed; this was enlarged with rongeurs and the dura found covered with granulations nearly half an inch in height. The bone was then removed in every direction with rongeurs till the opening extended beyond the area of dural granulations, making an opening in the skull about two inches in diameter. The granulations were covered with pus, but no marked collection was found except

in the extreme posterior portion of the wound, where two drachms were evacuated, which I at first thought came through a fistula in the dura; but on removing the granulations with a curette, the dura was found to be unperforated, and the collection of pus was evidently a pocket in the granulation tissue. The galvano-cautery was used to check obstinate oozing in the scalp, the upper parts of the wound were united by sutures and the rest packed with aseptic gauze.

From this time there was no further pain; the wound remained completely aseptic and was dressed about every fifth day; convalescence and healing were rapid. On January 13th he was allowed his clothes; and on February 1st went home, returning for occasional dressing. On March 17th both the dural and mastoid wounds were entirely healed; the tympanic swelling had been subsiding gradually, but had not then wholly disappeared; the hearing for the voice was 3/25; the general condition perfect. No signs of the cranial opening could be felt; it was apparently closed firmly by bone.

The temperature chart is interesting in that it gave no indication of the serious condition within the skull, 99°F. being the highest record just before operation, when there was extensive suppurative pachymeningitis going on. The aseptic condition attained in the wound I attribute entirely to the very thorough removal of the granulations by the curette. The case is further

interesting, not only in showing the insidious character of some of the otitic brain complications, but also the value of thoroughly exposing the ear-cavities and following the disease inward wherever it may lead.

CASE III. Chronic suppuration of the tympanum, caries of the antrum-roof and extra dural abscess.

J. McG., a woman, aged twenty-one, with a chronic suppuration of the left tympanum of eight months' duration entered the infirmary on November 6, 1896, complaining of pain in the ear for the last four days. The lower half of the drum-membrane was destroyed, and through the perforation a medium-sized polypus projected, which was removed with the snare, and bare bone was felt on the promontory. The mastoid, antrum and tip were slightly sensitive to pressure, but without external swelling.

Under the use of Leiter's ice-coil to the mastoid and hot douching of the meatus, both the pain in the ear and the sensitiveness of the mastoid improved until November 11th, when she waked at 1 A. M. complaining of severe pain in the ear, which was soon followed by a severe chill lasting half an hour; after this she slept well, and the next day appeared as usual till 3 P. M., when she had another severe chill with a temperature of 107.4° F. The temperature fell six degrees in the next hour but the patient was delirious, vomiting and very restless, and once there was distinct twitching of the right hand for two or three minutes. Examination of the eyes by Dr. Carleton showed no marked changes in the optic nerves. Dr. James J. Putnam saw her with me, and although the delirium had passed into unconsciousness and the pulse was very weak, it was decided to operate.

Before etherization one-thirtieth of a grain of strychnia was given hypodermatically. On exposure of the mastoid, the cortex was apparently not inflamed; but on opening it with the gouge and mallet, about two drachms of very offensive pus was evacuated, but pus continuing to appear from the upper posterior portion of the mastoid, the roof of the antrum was fully exposed and found to be carious over a spot about one-quarter of an inch in diameter, and pus was exuding from within the skull through a carious fistula. The dura of the cerebrum was exposed by removing the entire roof of the mastoid and for half an inch up the squamous bone through the linea temporalis; it was covered with red granulations over the carious bone and red, but smooth, for about half an inch around the granulations. The entire amount of pus within the cranium was only a few drops. The wound was cleansed by wiping, and packed with iodoform gauze. The pulse improved steadily from the time the bone was opened, and four hours after the operation consciousness returned and she recognized her father. Strychnia, one-thirtieth of a grain, was given after the operation.

November 12th. She was perfectly conscious and free from pain.

November 13th. The dressings were changed; there was a small amount of offensive pus in the depth. Dr. Daley reported streptococci and a bacillus, single and combined, in the culture from the operation; the bacillus resembling somewhat, but not absolutely, the tubercle-bacillus.

November 14th. Very comfortable, taking nourishment well.

November 15th and 16th. About the same, but some pain in the ear.

November 17th. Involuntary urination six times, and a convulsion lasting three minutes, with limbs rigid, head thrown back, eyes staring and frothing at the mouth, followed by dulness of intellect and wrong answers to questions. A change of dressings and evacuation of about three drops of pus seemed to give relief, and she became perfectly rational again.

For the next three weeks the patient gained steadily; there were no more convulsions, very little pain, no return of delirium; most of the time she was bright and cheerful, although occasionally fretful, but every night the urine was voided involuntarily during sleep. The wound was dressed daily, the pus became more abundant and more offensive, and as carious bone could be felt in the wound another operation was advised.

December 13th. Under ether the squamous bone was exposed, a part found loosened, and a semilunar sequestrum one and a quarter inches long and seven-

patient was then discharged to the out-patient department.

As the swelling of the drum-membrane disappeared, a large perforation of Schrapnell's membrane was seen, through which carious bone could be felt within the epitympanum in the region of the head of the malleus; and on March 19th an operation for carious ossicles was done, and the drum-membrane and malleus removed, together with a large quantity of granulations from the fissure of Rivini. The entire head of the malleus had been lost by caries and the neck was still carious; the incus was not found, and had probably been destroyed. The tympanum was syringed every three days, kept packed with aseptic gauze, and in three weeks all discharge had ceased.

One of the most interesting features of the case is the temperature chart, which shows such a slight variation from the normal between the first and second

eighths of an inch broad, was removed, evacuating about an ounce of yellowish-green, very offensive pus. The dura was covered with granulations. The sequestrum was eroded externally, but its inner surface was smooth and showed the groove of the middle meningeal artery.

For the next five weeks, although the general condition steadily improved and the patient was about the ward, the discharge continued abundant and very offensive, both from the mastoid and from a pocket between the dura and the squamous bone, and any retention of pus in this pocket produced headache. Examination of the blood by Dr. Putnam showed leucocytosis.

As carious bone could be felt in the mastoid and was suspected again in the squamous, on January 17, 1897, a third operation was performed by an incision upwards and backwards from the previous cut, which revealed newly-formed bone with pus exuding from beneath it; this was removed by the rongeur, and the greater portion of the squamous found to be a loose sequestrum, which was removed, evacuating two drachms of very offensive pus. The dura was covered with soft granulations, which were entirely removed with the curette, leaving the membrane smooth. The second step of the operation consisted in thoroughly clearing out the mastoid, where at the depth of an inch and a half forwards, a second sequestrum was felt and removed; this proved to be the posterior portion of the labyrinth including two of the semicircular canals. The entire field of operation was doused with distilled water and packed with iodoform gauze. There were now three wounds: one to the dura, and one to the labyrinth and a purulent tympanum. The two first continued aseptic, granulated rapidly, and in three days the communication between the mastoid and tympanum had closed. By February 5th the dural wound had healed and the mastoid was granulating well, and by March 1st was healed also, but there was still offensive discharge from the tympanum. The

operation, from November 12th to December 13th, notwithstanding a considerable collection of pus on the dura. During this time the only symptoms were one convulsion on November 17th, and constant involuntary urination during sleep only.

This case shows well the complicated nature of these suppurations within the bone; for there were practically three foci of disease, the caries of the antrum-roof with the extra-dural abscess, the necrosis of the labyrinth and the caries of the ossicles, all of which had to be got rid of before the disease was cured.

Four months after the healing the patient remained well and the ear was absolutely dry and free from all swelling.

THE CHEMICAL ANALYSIS OF THE GASTRIC CONTENTS.

- I. METHOD OF ANALYSIS FOR USE IN CLINICAL WORK.
- II. RECORD OF THE ANALYSES OF THE GASTRIC CONTENTS OF FIFTY HEALTHY INDIVIDUALS.

BY HENRY F. HEWES, M.D.,

Assistant in Chemistry, Harvard Medical School, Boston.

I. METHOD OF ANALYSIS FOR USE IN CLINICAL WORK.

To the physician who would utilize the investigation of the products of gastric digestion, as an aid to the diagnosis and treatment of his cases, there are two requisites. These requisites are (1) a reliable method of investigation; (2) a series of results for comparison, obtained by the application of this method to the product of the normal gastric digestion.

The development of a systematic method of investigation is dependent upon the collected knowledge of the subject of gastric digestion in health and disease. This knowledge is, stated briefly, as follows:

The digestion of food in the stomach occurs through the agency of a mineral acid (hydrochloric acid), a proteolytic ferment (pepsin), and a coagulating ferment (rennin), all produced from the glands of the mucous membrane of the stomach. Under the com

bined action of these physiological agents the proteid elements of the ingested food are digested.

The secretion of the hydrochloric acid begins immediately upon the ingestion of the food. The secreted acid at once combines with the native proteids of the food, forming acid proteids. It also acts upon the pepsinogen in the gastric glands forming pepsin.¹ The secretion of the acid continues until the affinities of the native proteids for acid being satisfied, a certain amount of superfluous (free) hydrochloric acid obtains in the stomach.

Coincident with the appearance of this free hydrochloric acid the activity of the pepsin ferment begins.² Under the influence of this pepsin in free HCl, the acid proteid products are converted with increased rapidity to albumoses and peptones. The rennin ferment is produced from the beginning of digestion, in part existing preformed in the cell of the mucous membrane, in part being formed by the action of the secreted acid upon the rennet zymogen. Under its influence the casein of food is digested to a coagulated and a soluble proteid.³

The products of digestion are in part absorbed, in part expelled in small quantities during the process of digestion. The greater part of the contents is, however, expelled *en masse* into the duodenum at the completion of digestion (Richet and Kühne). Whatever products are absorbed are replaced by water secreted by the stomach.

The mixed contents of the stomach will contain in the earlier stage of digestion—

(1) The elements of the ingested food, proteids, albuminoids, carbohydrates, fats, mineral and organic salts and extractives.

(2) The acid proteids and acid salts, the products of the combination of the secreted hydrochloric acid with the proteids and mineral salts of the food.

(3) The ferments, pepsin and rennin and the rennet zymogen.

(4) The products of the action of rennin upon casein. The principal proteids present are the native proteids and the acid proteids.

In the later stage of digestion the contents will contain the above substances except the organic salts, and, in addition, free hydrochloric acid and certain organic acids due to the action of the free HCl upon the organic salts of the food.⁴

The principal proteid substances present are albumoses and peptones.⁵

In pathological conditions of the stomach we may find absence or diminution of one or more of the physiological agents of digestion; and in addition the presence of certain abnormal substances not produced in the normal organ. These last substances are principally certain organic acids, lactic acid, butyric acid, acetic acid.

These substances are present in the normal contents only in the amount in which they or their salts are contained in the ingested food. In pathological conditions of the stomach they may be produced in considerable amounts as a result of the fermentation of the foods, principally the carbohydrate foods.

The particular fate of the different food elements in the stomach is as follows:

The native proteids are transformed in turn to albuminates, albumoses and peptones.

The albuminoids are to some extent digested, to some extent remain unaltered: thus gelatin is transformed to gelato-peptone, keratin is unchanged.⁷

The carbohydrate food is not digested by the agents of gastric digestion. The hydrochloric acid of the gastric juice has the power of inverting cane sugar, but aside from this the gastric secretions exert no influence upon the carbohydrates.⁹ A certain amount of amylolytic digestion does, however, occur in the stomach under the influence of the ptyaline of the saliva brought into the stomach with the food. The digestion of cooked starch goes on in the stomach through the influence of this ptyaline until inhibited by the increasing acidity of the contents.¹⁰

The fats are not digested in the stomach. The proteid envelopes of the fat cells are digested away, allowing the fat globules to run together and thus preparing the fat for the action of the intestinal digestion.¹²

The duration of digestion in the stomach, the rapidity of the appearance of free hydrochloric acid in the contents and the quantity of the secretion of the physiological agents necessary for complete digestion are directly dependent upon the quantity and quality of the food.¹³

Thus 100 gm. of raw beef *plus* 300 c. c. of water are digested in two hours.¹⁴ The same amount of beef roasted takes three hours. The duration of the digestion of an Ewald test breakfast (1 roll, wgt. 35 gms., and 300 c. c. of water) is from two to two and one-half hours. The digestion of a Leube meal (soup, meat and bread) is from six to seven hours.¹⁵

Free hydrochloric acid appears in the normal stomach from 15 to 20 minutes after the ingestion of 35 gm. of bread with water, 25 to 35 minutes after the ingestion of twice this amount (70 gm.), 25 to 35 minutes after 60 gm. of meat, 60 to 90 minutes after egg albumin, 45 minutes after a mixed meal of bread, meat and vegetables. The addition of fat to a meal delays the appearance of free HCl. The replacing of a certain amount of meat by a potato delays the appearance of the HCl.

The total amount of the free hydrochloric acid may rise after a light meal (Ewald meal) to 2.2 gm. per mille, after a full meal (Leube) to 3.3 gm. per mille.¹⁶ This maximum mark is reached from one to one and one-half hours after an Ewald meal, from two to three hours after a Leube meal.

Upon the facts contained in this review of the function of gastric digestion is based the method of investigation. It is clear from this review that the important points to be investigated are: the presence and amount of the physiological agents of digestion; the

evidence of their action upon the food; and the presence or absence of certain abnormal products. We have found that the time of the appearance of these agents and the amounts of them secreted vary according to the quantity and quality of the food ingested. To judge of the status of these agents in a given case therefore, we must obtain the contents of the stomach in that case at a given time after a definite meal, subject these contents to a systematic examination, and compare the results of this examination with standard results obtained from an investigation of the contents of the normal stomach in a series of cases under the same conditions.

The first step in the development of the method is the choice of the meal. This test meal should contain the ordinary elements of mixed food, that is, proteids, albuminoids, carbohydrates, and fats. It should also contain none, or as small amounts as possible, of those substances the production of which is peculiar to the pathological conditions of the stomach, that is, lactic, butyric and acetic acids.

Of the meals which have been proposed as test meals we may mention those of Ewald¹⁷ of Leube and Riegel,¹⁸ of Reichman,¹⁹ of Jaworski,²⁰ of Klemperer,²¹ of Boas.²² Two of these only are in common use for general work, that of Ewald and that of Leube and Riegel.

The Ewald test breakfast consists of one baker's roll, weight about 35 gm. and 300 c. c. of water, or of tea without milk or sugar. According to König's analysis, such a roll contains seven per cent. of nitrogen, one-half per cent. of fat, four per cent. of sugar, and 52.5 per cent. of non-nitrogenous extractive substances, to which one per cent. ash must be added.²³

This meal thus contains the various nutritious ingredients, albuminoids, starches, sugars, plant albumins, salts and fat.

The Leube meal consists of 400 gm. of soup, barley or flour soup, 60 gm. scraped beef, 50 gm. of wheat bread and 200 c. c. of water.

The use of both these meals may be necessary — in some cases one, in some the other, in some both. In a majority of cases, however, but one meal has to be resorted to; and for this general work the Ewald meal is the superior. This superiority of the Ewald meal is based upon the following comparative data:

(1) The Ewald meal contains lactic acid, if at all, in amounts too small to react to the ordinary approved tests.²⁴ The Leube meal, on the other hand, contains a considerable amount of lactic acid.²⁵ As the production of lactic acid in the stomach is a symptom of pathological conditions, we have thus in the presence of this acid after the Ewald meal positive evidence of abnormal conditions, which evidence cannot be obtained by the use of the Leube meal.

(2) The quantitative results in regard to the amount of the hydrochloric acid secreted and the period of the appearance of the free hydrochloric acid vary

within much more extended limits in the normal after a Leube meal than after an Ewald.^{26 27}

The considerable amounts of organic acids and acid salts which may be present in the Leube meal make rough estimations of the hydrochloric acid less reliable and accurate estimations more laborious than with the Ewald meal, with its insignificant amount of these substances.

A fourth advantage of the Ewald meal lies in the fact that it can be taken by patients with disordered digestive functions, with much less difficulty than the Leube.

It is true that the Ewald meal is not as strong a test of the digestive function as the Leube. A patient might have sufficient digestive capacity to completely digest an Ewald meal, and yet not sufficient to digest the ordinary mixed meal taken by a person of health and vigor. If this is the case, the deficiency will appear in the quantitative results obtained after the Ewald meal. And where such a condition is suspected or indicated, a Leube meal can be given after the Ewald test has been applied.

The Ewald test breakfast is given on a fasting stomach. Thus the meal may be given at 8 A. M., the patient having fasted since the dinner of the night before.

One hour after ingestion of the meal, the stomach tube is passed and the contents expressed.

The choice of one hour as the period of elapsed digestion before expression is founded upon experimental research. The most complete information can be secured if the contents be obtained at the period when all the physiological agents of digestion are present and active, and when the quantity of these approaches the maximum. This period has been found to be practically one hour after the ingestion of the Ewald meal.

As it is impossible, in ordinary clinical work, to obtain the contents in each case at exactly one hour after ingestion, I have this year made an investigation for the purpose of determining the effect of a longer interval than one hour upon the results in regard to the important conditions investigated.

The investigation consisted of the examination of the contents expressed one hour after an Ewald meal in fifteen normal cases, and an examination of the contents expressed one and one-half hours after this meal in fifteen cases. The results may be seen in the following table of averages:

TABLE 1.

	1 hour.	1½ hours.
Average quantity of mixed contents	120 c. cm.	100 c. cm.
Average total acidity	2 gm. p. m.	2.01 gm. p. m.
Starch present	2 cases	2 cases
Erethrodextrin present	8 "	6 "
Albumin present	15 "	15 "
Free HCl present	15 "	15 "
Lactic acid present	0 "	0 "

The conclusion to be drawn from these results is, that the conditions, the estimation of which is of importance in clinical work, do not vary in the period between one hour and one hour and a half after ingestion of the food, to an extent sufficient to affect the significance of the results.

For practical work, then, the contents may be expressed at a period between one and one-half hours after ingestion of the meal.²⁸

²⁷ Langruth: Loc. cit.

The tube used is a soft rubber tube, 75 to 90 cm. in length. The end of this tube is introduced to the pharyngeal end of the esophagus and swallowed by the patient. When the tube has reached the stomach the contents are expressed.²⁹

The simplest method of expression is that suggested by Ewald. This consists of pressure of the hand upon the epigastrium and forced vomiting by the patient. The end of the tube is moved up and down in the stomach during the expression. As a rule, practically all of the contents can be obtained by this method. I have repeatedly tested its efficiency by following the expression with siphonage by the introduction of water.

Another excellent method of expression is aspiration. An aspiration bulb with a short rubber tube on each end is attached to the stomach tube. By alternate compression and expression of the bulb, under the control of appropriate stopcocks, the contents may be successfully aspirated.³⁰

The expressed contents are measured, mixed thoroughly and subjected to the chemical analysis. The aim of this analysis is —

(1) The detection of the presence of the physiological agents of gastric digestion — the hydrochloric acid, pepsin and rennin.

(2) The determination of the quantity of these agents.

(3) The detection of certain abnormal products peculiar to definite pathological condition, if present — as lactic acid.

(4) The testing of the digestive capacity of the contents as removed.

The reason for these determinations and their value is clear from the consideration of the digestive function which has preceded. The integrity of the function is dependent upon the presence and sufficient amount of the physiological agents.

The failure of any agent, or of its normal amount, may at the same time point to the malady in a given case, and suggest a treatment.

The presence of the abnormal substances not produced in the normal stomach is itself an indication of a pathological process, and to some extent of the nature of this process.

Of secondary value may be the determination of the separate products of the proteid and carbohydrate digestion in the stomach.

Some writers ascribe considerable importance to these tests, especially the tests for starch and dextrin in the gastric contents; but recent works and my own observations, given later in this paper, tend to show that very little if any useful information can be obtained by these tests.³¹

In detail the chemical analysis includes the following determinations:

The reaction.

The presence of free acids.

The qualitative determination of free hydrochloric acid, lactic acid, butyric acid, acetic acid, pepsin, rennin and the zymogen.

The quantitative determination of the total acidity, and of the total hydrochloric acid and of its factors, the total free and total combined HCl.

The determination of the digestive capacity of the contents.

In certain cases the following determinations may be useful, in addition to the above test:

The qualitative determination of starch, erethodextrin and achrodextrin.

The qualitative determination of native proteids, acid albumin, albumoses and peptones.

The quantitative determination of the total organic acids.

The quantitative determination of the total acid salts.

The determinations of the hydrochloric acid of the contents include:

(1) The detection of free hydrochloric acid.

(2) The quantitative estimation of the total free hydrochloric acid.

(3) The quantitative estimation of the total combined hydrochloric acid.

(4) The quantitative estimation of the total secreted hydrochloric acid, that is, the free *plus* the combined hydrochloric acid.

The hydrochloric acid secreted by the stomach during digestion is disposed of in four ways. One portion combines with the inorganic bases of the food or of the saliva.

As the Ewald meal is in infusion acid, the amount of acid used in this way in cases examined by this method is practically that necessary to neutralize alkaline salts of the saliva.

This portion of the hydrochloric acid is not adaptable for the digestion of the food and does not appear in the quantitative determinations of acidity.

A second portion combines with the proteid or albuminoid substances either normal in the stomach, as mucin, epithelial cells, pepsinogen, rennin zymogen, or produced there in pathological conditions.

A third portion combines with the organic bases of the food, the proteid elements — to form acid proteids.

A fourth portion, which appears only when the first three portions are completed, exists as free acid.

These last three portions make up the total acid adaptable for purposes of digestion. They all appear in the quantitative determination of the hydrochloric acid — the first two as combined acid, the third as free acid.

The purely digestive function of the hydrochloric acid is, then, (a) to completely combine with the proteid food elements; (b) to combine with the pepsinogen and rennin zymogen, to liberate the ferments; (c) to serve as free acid, as a menstrum for the action of the pepsin upon the acid proteid combinations.

The object of our analysis in a given case is to determine if a sufficient amount of hydrochloric acid is secreted to perform this function.

From what has been said concerning the action of the acid, it is clear that this object is in some measure attained by the determination of the presence in the contents of free hydrochloric acid. Free acid present, we have the proteid affinities saturated, the ferments liberated and the conditions for peptic digestion present.

Even with free acid present, however, a more definite knowledge of the comparative vigor of the digestive function in a given case can be obtained by the determination of the total hydrochloric acid. Thus, of two cases, both containing free acid, one may contain only enough acid to give a small amount of free acid, the other enough to give a large amount. The second condition is, within certain limits, indicative of a more vigorous function and greater reserve force.

In cases where no free hydrochloric acid is present

²⁹ The distance from the incisor teeth to the fundus of the stomach is about twenty-three to twenty-six inches.

³⁰ Boas: Magenkrankheiten, s. 104.

³¹ See Ewald: Klinik der Verdauungskrankheiten, vol. ii, s. 51.

a quantitative estimation is our only method of determining how great a degree of hyposecretion is present.

For satisfactory work, therefore, both a qualitative test for free hydrochloric acid and a quantitative estimation of the total hydrochloric acid are necessary.

For the determination of the presence of free hydrochloric acid there are four good tests suited to practical work: these are Gunzburg's phloroglucin-vanillin test, Boas's resorcin test, Töpfer's di-methyl-amido-azo-benzol test, and the 00 Tropeolin test.

Gunsburg's reagent consists of phloroglucin 2, vanillin 1, absolute alcohol 30.³² One drop of the contents is heated on a white dish over a water-bath, and one drop of the reagent added. If free hydrochloric acid be present, a red zone of crystals is formed.

Boas's reagent consists of resorcin 5, sacch. alb., 3, spiritus dil. ad., 100. The test is performed in a manner similar to that described for the Gunzburg. Free hydrochloric acid gives a purple-red color.³³ These two reagents, the Boas and the Gunzburg, give no reaction whatsoever with organic acids, and are not interfered with by peptones or acid salts.

The 00 Tropeolin test consists of the addition of one drop of a saturated alcoholic solution of 00 tropeolin to one drop of the contents over a water-bath. Free hydrochloric acid gives a deep bluish-purple color. Organic acids give an orange color; acid salts a tawny yellow.

Töpfer's reagent consists of a half-per-cent. alcoholic solution of di-methyl-amido-azo-benzol. One drop of this reagent is added to a portion of the contents in a test-tube. If free hydrochloric acid be present a carmine-red color appears. This reagent gives a brownish-red color with organic acids.³⁴

All four tests are of about equal delicacy in testing straight solutions of hydrochloric acid. Where the acid is mixed with other substances, particularly with organic acids, as in the gastric contents, this equality of the different tests does not hold. In cases where considerable amounts of organic acid are present it is impossible to make an accurate reading from the Töpfer test. In other cases, owing to conditions not thoroughly understood, the Gunzburg test will react while the 00 Tropeolin fails, or the Töpfer test work where the Boas fails, or *vice versa*. It is my custom in general work to depend upon all four reagents. The Gunzburg test I have found the most satisfactory for the varying conditions. I therefore test the contents first with this test. If it reacts, free hydrochloric acid is present. If it fails, the Boas, Töpfer and 00 Tropeolin tests are tried in turn. It is only when a positive test is lacking with all four that free hydrochloric acid is recorded absent.

The methods for the quantitative determination of the hydrochloric acid are of several kinds. Three type methods serve to illustrate the different principles employed in the various methods:

(1) Methods based upon the determination of the total hydrochloric acid by precipitation and estimation of the total chlorine present.

(2) Methods based upon the determination of the total HCl by estimation of the acidity of the ash.

(3) Methods based upon the determination of the total HCl by the reaction of color reagents.

The precipitation method is best represented by the

method of Martius and Luttke, which is the most accurate of all the methods of this class.³⁵ This consists of the estimation of the total hydrochloric acid by determination of the total chlorine of the ash not present as in the form of chlorides. This method, as all the accurate methods of this class, is too difficult for clinical work.

The second type of method is represented by the method of Seeman.³⁶ This method consists of (a) the neutralization of the total acidity of the contents with soda solution, in known amount; (b) the reduction of the contents to the ash, thereby driving off all the organic compounds; (c) the estimation by titration with decinormal acid solution of the acidity lost by this reduction; (d) the estimation of the total hydrochloric acid by subtraction of the lost organic acids total from the total acidity. This method is very simple. It is not, however, absolutely accurate, since the total acidity due to acid salts is contained in the total recorded as total hydrochloric acid.³⁷

A review of all these precipitation and ash methods produced up to 1891 may be found in Martius and Luttke's "Magensaure d. Menschen."

The method of the estimation of the total hydrochloric acid by color analysis includes the following determinations:³⁸

(a) The determination of the total acidity by phenothalein.

(b) The determination of the total acidity due to free acids and acid salts by alizarin or Congo red.

(c) The determination of the total combined acids by subtraction of b from a.

(d) The determination of the total free hydrochloric acid by phloroglucin-vanillin or di-methyl-amido-azo-benzol.

(e) The determination of the total hydrochloric acid by the addition of c and d.

This color-analysis method has not the absolute accuracy of the precipitation methods.

It is, however, of sufficient accuracy for comparative work, and has the advantage of a simplicity fitting it for ordinary clinical work.

The details of this color-analysis process are as follows: The estimations are all made by titration of the contents with a decinormal solution of sodic hydrate.³⁹ Each cubic centimetre of this soda solution is capable of neutralizing 0.00365 gm. of hydrochloric acid. The estimation of the total acidity (a) is made by titration against an indicator phenothalein. This reagent gives a red color in an alkaline solution, no color in acid solution. Ten cubic centimetres of the mixed contents are diluted with water, and two or three drops of a one-per-cent. alcoholic solution of phenothalein added. To this mixture the decinormal soda solution is added from a graduated burette until a definite red color appears and remains after shaking. The presence of the red color shows that all the acid present has been neutralized.

By multiplying the number of cubic centimetres of decinormal soda solution used (x) by 0.00365 gm., we obtain the total acidity, in equivalents of hydrochloric acid, of the ten cubic centimetres of contents, and from

³⁵ Martius u. Luttke; Magensaure d. Menschen, Stuttgart, 1892.

³⁶ Seeman: Zeitschr. f. klin. Med., Bd. v, s. 273.

³⁷ Hari: Archiv. f. Verdauungskrankheiten, Bd. ii, H. 203.

³⁸ This plan of analysis is that originated by Töpfer, with some modification of the tests. Töpfer: Zeitschr. f. Physiol. Chemie, Bd. xix, H. 1.

³⁹ One-tenth molecular wgt. of Na OH+1000 c. cm. distilled water = 4 gm. to 1000 c. cm.

³² Centralblatt f. klin. Med., No. 40, 1887.

³³ Boas: Diagnostik, 2d Auflage, 1891, s. 134.

³⁴ Töpfer: Zeitschr. f. Physiol. Chemie, 1894, Bd. xix, H. 1, s. 104.

this result the per cent. or per mille amount of acid is estimated. (See bottom of next column.)

The estimation of the total acidity due to free acids and acid salts (*b*) is performed in the same manner, using Congo red as the preliminary indicator and alizarin as the final indicator.

Congo red paper, prepared by dipping filter paper into a strong aqueous solution of Congo red, turns a clear blue color in the presence of free HCl, purple in the presence of organic acids and a dull brown with acid salts. In the presence of combined acids it does not change color. In this test the decinormal solution is added to a given amount of the contents until a drop of the mixture fails to give any change of color to the Congo red. The reading taken at this point is recorded as the preliminary record of the amount of free acids *plus* acid salts present.

An aqueous solution of alizarin monosulphonate of soda (one per cent.) of a yellowish color gives no change of color when added to a solution containing free acids or acid salts, but gives a purple color in alkaline solution or in an acid solution, the acidity of which is due to combined acids alone. Decinormal soda solution is added to a portion of the contents to which two or three drops of a one-per-cent. solution of alizarin has been added, until a purple color is obtained. The appearance of this color marks the neutralization of the free acids and acid salts. It is the final record of the amounts of these substances.

The alizarin test is the more accurate and should be taken as the final index where it is possible to get an accurate result with it.

The reason for employing both the Congo red and alizarin in this estimation is that it is impossible in some cases to make an accurate reading by the alizarin test, the point of transition from a yellow to a purple color not being abrupt.⁴⁰

In such cases the record by the Congo-red test must be used. The reading by this test will always be less than the alizarin test by about 0.1 to 0.3 c. c. decinormal solution to 10 c. c. contents, as the first records the end of the acid reaction while the latter records the actual alkaline reaction.

By the subtraction of the total acidity due to free acids *plus* acid salts (*b*) from the total acidity (*a*), the acidity due to combined acids is obtained (*c*). Where free hydrochloric acid is present all of the combined acid is combined hydrochloric acid, whatever organic acids may be present.⁴¹

The estimation of the total free hydrochloric acid (*d*) is performed by titration with the decinormal soda solution until the test for free HCl can no longer be obtained. Ten cubic centimetres of the contents to which two drops of the one-half-per-cent. alcoholic solution of di-methyl-amido-azo-benzol have been added are titrated with the soda solution until the red color of the mixture gives place to a yellow color. This point determines the neutralization of the free HCl. This is the simplest method of performing this test. It has, however, one great disadvantage as a test for general use. Where any considerable quantity of organic acids is present in the contents, the point of transition from a carmine-red to a yellow color is not sharp and cannot be accurately determined.⁴² The organic acids give a brownish-red color which is not

unlike the much diluted carmine red of the mineral acids.⁴³ For this reason I have used phloroglucin-vanillin as the indicator in place of or in addition to Töpfer's reagent. The test with this reagent can never be confused by the presence of organic acids or other constituents of the gastric contents. Ten cubic centimetres of the contents are titrated with the soda solution until a drop of the mixture fails to give the free HCl reaction with phloroglucin-vanillin. The last reading before the failure of the test is taken as the measure of the hydrochloric acid. Thus, if the test responds after the addition of 4 c. c. one-tenth soda solution and fails with the addition of 4.1 c. c., the free HCl in the 10 c. c. of contents = $4 \times .00365$ gm.

The total hydrochloric acid (*e*) is determined by the addition of the total combined HCl (*c*) and the total free HCl (*d*), in cases where free HCl is present. Where no free HCl is present the total hydrochloric acid can be estimated by the following method (Mintz method):

To 100 c. c. of the contents add a decinormal solution of hydrochloric acid until the test for free HCl with phloroglucin-vanillin is obtained. Since the limits of the Gunzburg reaction is 0.036 gm. per mille HCl (that is, one cubic centimetre decinormal soda solution to 100), the difference between this figure and the amount of decinormal soda solution used represents the amount of combined HCl present in the 100 c. c. of contents, that is, the total hydrochloric acid present. For example, if Gunzburg's reaction were first positive after the addition of six-tenths of a cubic centimetre decinormal HCl solution to 100 c. c. contents, then $1 - 0.6 = 0.4$ c. c. one-tenth normal HCl is the amount of HCl already present in 100 c. c. of contents. This process can be conducted with less than 100 c. c. if necessary.

The total combined acid (*c*) in cases where no free HCl is present represents the sum of the combined hydrochloric and combined organic acids. Where no organic acids are present by the qualitative tests the total combined acid (*c*) may be taken approximately as the total hydrochloric acid in these cases.⁴⁴

As an example of the application of this method, I give the results of the examination of the contents of a normal stomach — contents expressed one hour after an Ewald test meal.

Amount of contents, 160 c. c.

Amount of filtrate, 85 c. c.

A. Ten cubic centimetres mixed contents *plus* two guttæ phenothalein gave red color on addition of 7 c. c. decinormal soda solution. ∴ Total acidity of 10 c. c. contents = $7 \times .00365$ gm. = 0.02555 gm. HCl = per mille $\frac{10.0}{100} \times 0.02555 = 2.55$ gm.

B. Ten cubic centimetres contents with Congo-red paper fail to give change of color at 4.7 c. c. decinormal NaOH ∴ 1.71 gm. per mille HCl = preliminary record total free acids *plus* acid salts. Same 10 c. c. contents give purple color with alizarin on addition of 4.9 c. c. NaOH solution ∴ Total acidity due to free acids *plus* acid salts in 10 c. c. = $4.9 \times .00365 = 1.78$ gm. per mille (final record).

C. Total combined acid = A — B, that is, $2.55 - 1.78 = 0.77$ per mille.

D. Ten cubic centimetres contents titrated with NaOH failed to give red color with phloroglucin-vanillin, first, on

⁴³ Strauss: Deutsches Archiv. f. klin. Med., Bd. lxvi, H. 1.

Mohr: Loc. cit.

⁴⁴ The qualitative tests for lactic and butyric acids, etc., react to lactates and butyrates as well as the free acids.

addition of 3.2 c. c. NaOH solution — responded with 3.1 c. c. . . . Total free HCl = $3.1 \times .00365 \times 100 = 1.13$ gm. per mille.

E. Total hydrochloric acid = C + D, that is, $0.77 + 1.13 = 1.90$ gm. per mille.

F. Total acidity due to organic acids plus acid salts = B — D, that is, $1.78 - 1.13 = 0.65$ gm. per mille.⁴⁵

The whole process of quantitative determination by this method can be accomplished with simple apparatus within twenty minutes.

The results though not of absolute accuracy, are accurate for comparative work. For example, the delicacy of the test for free HCl is .05 gm. per mille. The total free HCl is thus for 3.1 c. c. NaOH solution not 1.13 per mille but 1.13 ± 0.05 per mille. Also the error incident upon the judgment of colors must affect the results in this method for absolute work. The above sources of error are, however, constant in comparative work, and thus do not affect the results.

A certain amount of the secreted HCl combines with the phosphates of the food, forming acid phosphates, which contribute to the sum of the total acidity of the contents. In some cases it may be useful to estimate these total acid salts and the total organic acids separately. This may be accomplished by the addition of the following method (Leo's method) of estimating the total acid salts to the scheme of analysis already given.⁴⁶

To 15 c. c. contents add one gramme dry powdered CaCO_3 ; shake, filter. Measure off 10 c. c. of filtrate; pass a stream of hot air through it to carry off the CO_2 ; add 5 c. c. CaCl_2 , add one drop of phenolphthalein, and titrate with decinormal soda solution. The total acidity of this last filtrate divided by two is the total acid salts contained in the 10 c. c. of contents. The CaCO_3 unites with all the acid elements of the contents save the acid salts, forming of the HCl calcic chloride, of the lactic acid lactate of calcium, etc. In the presence of the CaCl_2 thus formed twice the amount of decinormal soda solution is necessary to neutralize the acid phosphates as in the absence of CaCl_2 ; hence the division by two of the final result.

If this total acid salts (G) be subtracted from the total of organic acids plus acid salts obtained as described above, but after the addition of 5 c. c. of concentrated solution of CaCl_2 to the 10 c. c. of contents (B_2), we have as a result of our subtraction the total organic acids (see addenda to analysis).

This plan of analysis is, as I have stated, a modification of the method published by Töpfer.⁴⁷ The modifications consist in —

(1) The addition of the Congo-red test for free acids and acid salts, to the alizarin test as given by Töpfer, in the quantitative estimation of these substances.

(2) The substitution of the phloroglucin-vanillin test for HCl, for the di-methyl-amido-azo-benzol test of Töpfer in the quantitative estimation of the HCl.

The reasons for these changes are given in the description of the methods (see preceding pages). As I have stated in the description referred to, the Töpfer tests are satisfactory for a majority of cases examined, but not for many cases, especially those with pathological conditions. The objection to the tests cited are

⁴⁵ If the acid salts are computed by the method given below we get the following addition to the above record. G total acid salts subtracted from B_2 (total free acids and plus acid salts in mixture with CaCl_2) = total free acids (H). Subtract total free HCl D from total free acids (H) = total organic acids (K).

⁴⁶ Leo: *Frankheiten der Verdauungs Organ*, Berlin, 1890.

⁴⁷ Töpfer: *Zeitsche. f. Physiol. Chemie*, Bd. xix, H. 1.

based upon the researches of Hari,⁴⁸ Strauss,⁴⁹ Mohr,⁵⁰ and upon my own experience in analyses of the gastric contents.

The pepsin of the gastric juice is produced from the pepsinogen formed in the glands of the gastric mucous membrane by the action of free hydrochloric acid upon this pepsinogen.⁵¹ Since pepsin may be found in gastric contents containing no free hydrochloric acid, it is probable that the secreted acid has combined with the pepsinogen before the affinities of the proteid foods are satisfied.⁵²

The pepsin acts only in the presence of free hydrochloric acid. The evidence of the presence of pepsin in the contents of a given case is assured by the capacity of this contents to digest albumin.

If free hydrochloric acid be present, the determination of the pepsin is conducted as follows: 50 mgm. of coagulated egg albumin is placed in 25 c. c. of the filtrate of the contents and the mixture kept at a temperature of 40° C. If pepsin be present, digestion of the albumin will occur. If no free hydrochloric acid be present in the contents, the same test is applied, the contents having first been brought to the proper acidity by the addition of hydrochloric acid.

These determinations performed in this way also enable us to form some rough quantitative estimation of the pepsin present. In the normal contents 50 mgm. of egg is entirely dissolved in 25 c. c. of contents within three hours. The acidity being normal then, either naturally or by addition of acid, a duration of the dissolution of the egg over three hours indicates a diminution in pepsin.⁵³

A more definite quantitative estimation, suited to practical work, may be made as follows:⁵⁴ A one-per-cent. solution of albumin (dry) containing four per cent. free hydrochloric acid is made up. This is divided into two portions of ten cubic centimetres each. To one portion five cubic centimetres of water is added, to the other five cubic centimetres of the filtrate of the gastric contents to be tested. Both mixtures are then placed at a temperature of 40° C. for one hour. The amount of albumin in each solution is then tested by means of an Esbach albuminometer, and from the comparative results the per cent. strength of the contents estimated. Thus, if the first solution shows six per cent. albumin and the second three per cent., the contents are said to have a 50 per cent. strength pepsin. The normal contents give from 80 per cent. to 90 per cent. by this test.

Rennin, the milk-curdling ferment of the stomach, is formed from its zymogen which exists in the cells of the gastric mucous membrane, by the action of the secreted acid. A certain amount of rennin can, however, be obtained by the addition of water to the mucous membrane even where no free HCl is present in the stomach. Rennin is active in acid, neutral or even feebly alkaline solutions.⁵⁵

The normal gastric contents contain both rennin and its zymogen.⁵⁶

The test for rennin is as follows: Ten cubic centimetres of the filtrate of the gastric contents is neutralized with decinormal solution of NaOH. To this ten cubic centimetres of neutral milk is added, and the mixture tested at 38° C. If rennet be present casein will form in ten to fifteen minutes.⁶⁷

The test for the zymogen is as follows in the absence of the ferment: To ten cubic centimetres of the filtrate made slightly alkaline add two cubic centimetres of a one-per-cent. solution of calcium chloride; then ten cubic centimetres of milk and heat at 38° C. If rennet is present casein will form. It is rare to find a condition in which rennet or the rennet zymogen is wholly absent, but a marked diminution of these substances is characteristic of certain morbid conditions.

In some cases, therefore, aid may be derived from a quantitative estimation of these substances.

The quantitative estimations for rennet and the zymogen are as follows: Part of the gastric filtrate is exactly neutralized, and portions of this diluted to different dilutions as one-tenth, one-fifteenth, one-twentieth. Five cubic centimetres of each dilution is placed with five cubic centimetres of neutral milk at 38° C., and the dilution at which the ferment ceases to be active ascertained. By comparing the result with normal results, any diminution and the amount of it can be observed. For the zymogen a portion of the filtrate is made alkaline; different dilutions made, one-tenth to one one-hundred-and-sixtieth; five cubic centimetres of dilution placed with one cubic centimetre CaCl₂ plus five cubic centimetres of milk; and the dilution where action ceases recorded.

Full tables of the normal amounts of the rennin and its zymogen in the normal conditions can be found in Friedenwald's article on the subject.⁶⁸

(To be continued.)

THE TUBERCULOUS DIATHESIS.

AN INQUIRY INTO THE CAUSES THAT LEAD TO PULMONARY CONSUMPTION.¹

BY CHAUNCEY REA BURR, M.D., HARV., P.H.B., YALE, SAN JOSE, CAL.

AMONG the morbid conditions associated with pulmonary tuberculosis, one of the most constant is a fatty liver. This lesion may be in the form of fatty degeneration, or fatty infiltration. Morphologically it is often impossible to distinguish between the two. The liver normally contains a certain proportion of fat, particularly after meals.

"This fat," according to Ziegler,² "is partly brought to the liver ready-formed and there deposited, and partly elaborated from albuminoid substances *in situ*." In diseased conditions the hepatic fat may be enormously increased, the increase depending either on increased production of fat or on diminished consumption of fat, or on both. Most authorities when treating of this subject in connection with pulmonary phthisis consider fatty liver a disorder of suboxidation. And so it is, but the reason ordinarily given, namely, embarrassed pulmonary respiration, is inadequate to explain all cases. For, as long ago pointed out by

¹ Read before the Medical Society of Santa Clara County, California, April 13, 1897.

² Path. Anat., 1881, sect. viii, chap. lviii, No. 487.

⁶⁷ Boas: Magenkrankheiten. Loc. cit.

⁶⁸ Friedenwald: Medical News, June 22, 1895.

Rokitansky, there are diseases characterized by embarrassed respiration, more profound than that of pulmonary phthisis, as, for instance, pulmonary emphysema, in which fatty liver occurs with nothing like the frequency it does in phthisis, while in other diseases in which the lungs are sound, as in tuberculosis of the bones, chronic dysentery and anemia, fatty liver occurs with comparative frequency. Some other factor than embarrassed pulmonary respiration must enter into the production of this pathological state.

It has seemed to the writer a promising subject to investigate, and one which might lead to a better understanding of the tuberculous diathesis. Accordingly, the question to be answered is: "Why should the liver of pulmonary phthisis so often be in a state of fatty degeneration?" It has been suggested by Fitz, that the administration of cod-liver oil is largely responsible for this condition. In some cases it may be, but it by no means follows that because oil is taken as a food it appears in consequence as oil in the tissues. It may be entirely oxidized to carbon dioxide. On the other hand, foods which are not fatty, as albumins and sugars, may appear as fat in the tissues. Foster mentions a pig³ in which 472 parts of fat were laid on for every 100 parts of fat taken as such in the food; while of every 100 parts of a mixed diet, including substances other than fat, 21.2 parts were retained in the body as fat. "Clearer proof than this," he says, "could not be afforded that fat is formed in the body out of something which is not fat."

It is well to understand, before proceeding further, to what uses the fat is put after it is formed. Thompson⁴ mentions several such uses, namely, to furnish energy for the development of heat; to spare the tissues from disintegration; to serve for the storage of energy.

Fat is, therefore, a fuel, a producer, if properly oxidized, of heat and power. It has already been stated that the fat found in the liver cell may be brought thither ready-formed or may be elaborated from albuminoid substances *in situ*.

Brunton⁵ gives a table which makes clear this latter change. According to this table, albuminous tissues split up into non-nitrogenous substances, as fat, etc., and nitrogenous substances, as leucine, tyrosine, etc. The fat is normally converted into carbonic acid and excreted by the lungs; while the leucine and tyrosine are converted into urea and pass off by the kidneys.

Smith⁶ says that "fat when entirely deprived of water consists of three elements only, namely, carbon, oxygen and hydrogen (C₇₇ O₁₁ H₁₂). When the fat is decomposed in the body these elements unite, so that the carbon takes a part of the oxygen and becomes carbonic acid, whilst the hydrogen takes another part of the oxygen and becomes water, any deficiency in the quantity of oxygen for this purpose being supplied by the inspired air."

An hepatic cell, therefore, in a state of fatty degeneration, is one in which the fat has been elaborated from albuminoid substances *in situ*. Furthermore, there has been some interference with the normal chemical process, for the change to stop at the fat formation and not pass on to that of carbon dioxide.

Fat is a fuel, burned up or oxidized in the vital processes of the cell. The fat droplets appear in the parenchyma of the cell shortly after the ingestion of a

³ Physiology, 1883, p. 533.

⁴ Practical Dietetics, 1895, p. 173.

⁵ Pharmacology and Therapeut., 1885, p. 360.

⁶ Foods, 1873, p. 45.

meal, and disappear in large part before the next meal. The oxygen necessary for combustion comes from without; in other words, the cell has a respiration: it breathes; and if it breathes there must be a respiratory mechanism.

Quain⁷ speaks of the streaming movements of cellular granules. "This phenomenon," he says, "can be seen to occur both in cells which are stationary and in those which are exhibiting ameboid movements. It consists in the protoplasm of the granules which are suspended in that substance." He refers the production of the phenomenon to contractions in the protoplasmic substance. Here, then, is the mechanism by which the cell breathes. If it contracts, it also expands, and probably draws in oxygen in the process through the cellular walls. As if to put the seal of *imprimature* on this supposition, he further says: "The contractility of protoplasm is dependent upon the supply of oxygen. If this be withheld, the movements will, it is true, proceed for a time as usual, but this is because protoplasm, like other forms of contractile substance, such as muscle, has the power of storing away and using oxygen in some form of combination. For it is found that the active manifestations will not proceed indefinitely in the absence of oxygen, but cease after a time, to be renewed only on the accession of fresh oxygen."

A cell, therefore, in which fat is not consumed, a cell, in other words, in a state of fatty degeneration, is a cell which has ceased to breathe sufficiently to oxidize its fat. This failure of respiration may be due to failure of oxygen in the body at large, or to intrinsic weakness in the cellular respiratory mechanism. Cases of the first class occur in any disease in which the lungs are involved or in which the oxygen-carriers, the red blood corpuscles, are involved. Such are pulmonary complaints of long standing, anemia, infectious diseases and the intoxications, as lead, syphilis, alcohol, etc.

Cases of the second class may develop independently of the first class, or may be the direct sequence of this. The stationary cells of the body are in relation with the nervous system. Stimuli sent through this manifest themselves in signs of cellular activity. One of these signs is cellular contraction, and this, as has been shown, is the probable essential feature of the cell's respiratory mechanism. Failure of contraction involves failure of nerve force, and this in turn involves lesions of the nerve substance. In the case of the liver, the nerve substance, or nervous supply, is derived from the hepatic plexus of the sympathetic system. Filaments from this accompany the hepatic artery in its ramifications in the portal canals. Any lesions of these filaments or of their supplying plexus must perforce affect the physiological functions of the hepatic cells.

It is astonishing that more attention has not been paid to the pathology of the sympathetic system. Most writers ignore it altogether or make but passing allusion to it. What few facts it has been possible to collect for the purposes of this paper are rather in the nature of processes common to nervous matter in general than to the sympathetic system in particular.

Broadly speaking, such processes may be divided into inflammatory and degenerative, the one often following or becoming merged in the other. Thus, cellular infiltration is followed by fibrous hyperplasia or

sclerosis and degenerative atrophy of the nerve elements. Among the specific causes which induce inflammation of the nervous structures may be mentioned typhoid, variola, acute rheumatism, pyemia, puerperal fever, ulcerative phthisis. Nor must syphilis, alcohol, lead and other mineral poisons be forgotten. It will be observed that these are the same disorders in which fatty glandular change is so common. Lead in particular gives rise to degenerative change in the intestinal plexuses. Wherever degeneration occurs, the nervous filaments on the distal side atrophy, and consequently cut out of circuit more or less completely the structures to which they are distributed. This is descending degeneration. There is also an ascending degeneration of more limited extent extending upward to the nearest ganglion cell. In such cases, the trophic centre is in the periphery, and hence the course of the degeneration is away from the cut-off base of supply.

Intrinsic weakness in the cellular respiratory mechanism is simply another name for cellular paresis and the anatomical basis of this is inflammatory or degenerative change, or both, in the nerves supplying the cells concerned. The fatty cell is an index of this condition, and the writer is firmly of the opinion that the majority of cases of fatty degeneration wherever situated will be found to be associated with a degenerative neuritis of the nerve supply. This has already been shown to exist in the case of Bright's disease by the researches of Da Costa and Longstreth,⁸ who found an apparently constant degeneration of the renal ganglia, along with the other lesions peculiar to the disease. The associated albuminuria may be due to a similar condition, for the blood vessels and the renal parenchyma have a similar nerve supply, and if the integrity of the one is attacked, the other must suffer also, and allow a leakage of serum albumin through their damaged walls. For all that is known to the contrary, the amyloid or lardaceous change may be due to a similar condition, for fatty degeneration is a constant concomitant with this disease.

In diabetes, it is estimated that half the cases are associated with a degenerated and fatty pancreas. In fatty degeneration of the heart a careful search would probably disclose degeneration of the cardiac ganglia. Eichhorst has demonstrated that section of the vagi is followed by fatty degeneration of the heart, and branches of the vagi terminate in these ganglia. In peripheral neuritis a dropsical condition of the limbs is often observed. All admit that this is due to paresis of the blood-vessels. If paretic blood-vessels in this situation allow their fluid contents to escape, will they not do the same in other situations? In short, there is good clinical evidence in support of the conclusion that a fatty cell is a paretic cell.

If the liver of pulmonary phthisis is so often in a state of fatty degeneration, it is because it is paretic. The cause of the paresis may be difficult to determine. From what has already been said, it will be understood that the site of the lesion may be either at the termination of the nerves in the hepatic parenchyma, or in the hepatic plexus. The former is probably the more frequent site of the two. Any glandular structure may be worn out by excessive use. Inflammation follows, then degeneration and atrophy. Here, then, is one cause of hepatic paresis—overwork. The liver of beer drinkers is often fatty and cirrhotic.

They also often develop pulmonary tuberculosis. Cattle fed upon malted grains become, after a time, emaciated and tuberculous. In both cases the liver is overworked. Again, from the position it occupies, the liver is peculiarly liable to septic intoxications. With the exception of fats, all the products of intestinal digestion pass through the liver on their way to the general circulation. Poisonous peptones and many other poisons are here rendered innocuous. But it is conceivable that the task may be too great and the liver itself be poisoned. Over-feeding and its consequent dyspepsia is therefore a frequent cause of a disordered and parietic liver.

Another cause is improper food. Strong meat is not for babes, nor is alcohol or starch for adults. The late Dr. Fothergill, of London, has set forth in his inimitable way the reasons why meat in excess is not a proper food for certain individuals.⁹ According to this authority, lithogenesis is reversion. Reversion to an archaic ancestry, which shared with birds, reptiles and fishes conditions of life which resulted in certain similar metabolic processes. Among these, he places the excretion of uric acid in place of urea. Birds excrete a solid urine rich in uric acid, but deficient in urea, as do also reptiles and fishes. The reverse is the case with mammalia. Here a fluid urine is excreted, rich in urea, but deficient in uric acid. The fetus *in utero* is a reptile with the potentialities of a mammal. Its circulation and heat production are reptilian, and it manifests a tendency to the reptilian uric-acid formation. "When it breathes," writes Dr. Fothergill, "as by the touch of an enchanter's wand, the circulation becomes that of the mammal, and its heat production that of a warm-blooded animal."

The uric-acid infarcts of infantile kidneys are well known, as well as the deposit of urates on infantile napkins. At puberty the uric-acid formation is largely left behind. Exceptionally it persists, and where before the passage of uric acid and its salts through the kidneys occasioned little or no irritation, it is, later in life a fruitful cause of Bright's disease and many other ailments. Most authorities agree that urea is excreted by the liver cells. Vaughn has shown that uric acid is excreted by leucocytes. The liver cell, therefore, excretes a fluid urine rich in urea, the leucocyte, a solid urine rich in uric acid—an interesting distinction, as showing the one to be mammalian in its development, the other reptilian. In hepatic disorders, a heavy output of urates is a very common occurrence; and as these disorders are generally plethoric in their character, it would seem as if the old contention was true, that urea is simply oxidized uric acid; or, to put it more in the language of this paper, that the liver cell being specialized and of the mammalian type, breathes more deeply and uses more oxygen than the reptilian leucocyte.

Again, Haig has shown¹⁰ that uric acid and the xanthin compounds from which uric acid is derived may be introduced with the food, particularly where a meat diet is used. A feeble liver, therefore, fed with meat peptones containing uric acid and xanthin, is easily upset and hepatic congestion and inflammation follow. Feebleness of hepatic function is often inherited. The diathetic state in which this occurs is called scrofulosis, and the frequent association of this with tuberculosis has long been recognized. Fothergill

says that the children of town dwellers in the second and succeeding generations are very apt to be lithogenetic. How common the type is the out-patient waiting-room of any metropolitan hospital will show.

There is the bulky personage of large frame, clumsy and rheumatic, with features like a blurred photograph, and the delicate, fragile creature of emotional temperament, feeble digestion, light lower jaw and arched palate. The air of cities is notoriously deficient in ozone, and this may have much to do with the persistence of the uric-acid diathesis, particularly as such patients improve when removed to the ozonized air of the sea-shore.

With regard to the use and abuse of alcohol, but little need be said. Its influence is sometimes beneficial, often deleterious. It robs the system of oxygen to satisfy its own needs. In addition, sclerosis develop under its continued use. Whether this is due to the alcohol itself or to the impurities which often accompany it does not appear to have been determined. Fusel oil is generally regarded as one of the offending factors.

Starch, while admitted by all as unsuitable for infantile digestion, is not so generally recognized as unsuitable for adult digestion. And yet it is often a stumbling-block to those of the dyspeptic habit. The secretions of the salivary glands, Brunner's glands, pancreas and liver may all be called on in turn to struggle with starch and convert it into glucose. Sugars, fats and albumins, on the contrary, are readily digested and absorbed. The axiom has already been stated that "any glandular structure may be worn out by excessive use." The constant struggle of a delicate organism to convert the starch into glucose is an illustration in point. If the truth could be known, it would probably appear that the diet of baked beans and doughnuts, common to so many American families, had much to answer for in the production of insufficient livers and pulmonary phthisis. The rice-eating Bengalee escapes gout, but falls a frequent victim to diabetes and consumption.

So far, the inquiry has endeavored to show the causes which lead to fatty degeneration of the liver, and the fact has been pointed out that this condition is often associated with tuberculous deposits in the lungs. It remains to study the one condition with the other and ascertain what relation, if any, exists between the two.

No time need be wasted over the proximate cause of pulmonary consumption. All admit its identity in the tubercle bacillus. This microbe is not an aggressive fellow. He requires time for development and quiet surroundings. The cultures grow slowly. On the other hand, the leucocyte is an aggressive fellow and is the sworn enemy of microbes in general. How happens it then, that the battle is often so languidly waged and that the victory so often rests with the peace-loving invader? For the very reason that there is peace in his immediate neighborhood. He has pitched his camp by the slow-flowing stream of dropsical fluid that exudes from parietic capillaries. He is not rudely jarred by draughts of air sweeping through the passageways of the lungs. On the contrary, he chooses the apices where the respiratory movement is normally slight, or some dependent portion of the lung already infiltrated with the serous exudate. The leucocytes hasten to do battle, and crowd about the seat of invasion in ever-increasing numbers. But

⁹ Keating: *Cyclopedia of Diseases of Children*, 1889, vol. ii, pp. 296-319.

¹⁰ *British Medical Journal*, October 3, 1896.

they have pushed their way into a practically airless region, and one impregnated with toxins. If Dr. Hirschfelder's contention is true that a toxin oxidized becomes an antitoxin,¹¹ then conversely a toxin unoxidized remains a toxin. The leucocyte cannot continue to elaborate germicidal nuclein without a supply of oxygen. If the supply is deficient its amoeboid movements cease and therewith its functional activity. The toxins clamor for oxygen, and so likewise do the leucocytes, with the probable results that the leucocytes perish, and the toxins continue toxins.

The evidence of a pulmonary paresis antecedent to the outbreak of tuberculosis is clinical rather than pathological. It rests on the fact of dullness on percussion over the affected area, and diminished respiration. These may precede by a considerable interval the demonstration of the presence of the tubercle bacillus.

The nervous supply of the lungs is derived from the anterior and the posterior pulmonary plexuses, which are formed by branches of the sympathetic and pneumogastric nerves. Section of the pneumogastric nerve, according to Ranney,¹² gives rise to a remarkable set of symptoms: the larynx is impaired in its action; there is dyspnea and hoarseness: the lungs are engorged and consolidated; sometimes there is hemorrhage; the heart is altered in its rhythm, accelerated, often irregular; swallowing is difficult; the liver loses its glycogenic function; the gastric functions are imperfect and there is constipation. These symptoms appear if both nerves are divided below the jugular ganglion. If only one nerve is divided, there is hoarseness, dyspnea, emphysema or pulmonary congestion. A paresis of the pneumogastric, therefore, would manifest similar symptoms, different in degree but not in kind. Such paresis may arise from direct injury to the pulmonary nerves, as is seen in pneumonia and capillary bronchitis, or from injury to some other branch of the vagus, in which case the pulmonary symptoms are reflex.

The pneumogastric, or vagus nerve has its origin in a nucleus near the lower part of the floor of the fourth ventricle, and terminates on the right side in the celiac and splenic plexuses, and on the left side in the hepatic plexus. The left pneumogastric is, therefore, more in touch with the liver than the right pneumogastric. In cases of tubercular deposits in the left lung the liver is more frequently found to be diseased than where the right lung is affected. This is a clinical point of some value, as directing attention to the liver in such cases. The nervous connection between the two explains this.

The pneumogastric communicates through its auricular branch with the glosso-pharyngeal, facial and auricularis magnus nerves, and consequently influences hearing (through the stapedius and laxator tympani muscles), the condition of the tonsils, soft palate and tongue, the muscles of facial expression, and those holding the ear close to the head, as well as the sensation and nutrition of the posterior scalp. Through its junction with the spinal accessory, it further influences the tonicity of the sterno-cleido mastoid and trapezius muscles. The other branches are distributed to the larynx, heart, esophagus and stomach.

A general paresis of the pneumogastric nerve would be evidenced by some such collection of symptoms as

the following: Hoarseness, dyspnea, pulmonary congestion, feeble cardiac action, dyspepsia, coated tongue, constipation, relaxed and edematous soft palate, catarrh, deafness, emaciated face, neck and upper extremities, prominent ears and silky hair on the posterior portion of the scalp. It is also a picture of many cases of pulmonary consumption.

As has been said, pneumogastric paresis may arise from direct injury to some one of its numerous branches. The frequency with which fatty liver occurs in pulmonary consumption points to this as the origin of morbid change in many instances. The interstitial framework of the organ, in which the supplying nerves ramify, becomes inflamed. A neuritis is developed which issues in degeneration, and is thus transmitted to the hepatic plexus and thence into the pneumogastric nerve. This would explain what to Ziegler is a mystery, namely, that the vagus is subject to degenerative change without any compression, inflammation, or other injury.¹³

Inflammation of the hepatic interstitial tissue at once suggests cirrhosis. Osler says,¹⁴ "A remarkable feature (in cirrhosis of the liver) is its association with acute tuberculosis. In seven cases of my series, the patient died with either acute tuberculous peritonitis, or acute tuberculous pleurisy. Pitt states that twenty-two and a half per cent. of the cases of cirrhosis dying in Guy's Hospital during twelve years had acute tuberculosis."

This clinical observation of the association with hepatic cirrhosis of pleurisy and peritonitis cannot be explained by any lesion affecting the branches of the pneumogastric nerve. But how about the phrenic nerve? This also supplies the liver, as well as the pleura and peritoneum. It further supplies the pericardium and diaphragm. The right phrenic ends in a small ganglion, from whence branches issue to the hepatic plexus, suprarenal capsule and inferior vena cava. The left phrenic ends in the phrenic plexus, a subdivision of the solar plexus which supplies all the viscera in the abdominal cavity. Peritonitis and pleurisy could thus both originate from injury to the branches of the phrenic nerve in the interstitial connective tissue of the liver.

It will be observed that the hepatic plexus receives the termination of the right phrenic and left pneumogastric nerves. A lesion here, originating from hepatic disease, could issue in paresis of the left pneumogastric nerve, the symptoms of which have already been given, while on the right side there might occur pleurisy, pleuro-pneumonia and defective respiration from paresis of the diaphragm. Nor must it be forgotten that the lower lobe of the right lung is packed tightly between the liver and the ribs, and might easily be compressed by enlargement of the liver, thus causing pressure neuritis of the pneumogastric and phrenic filaments and pneumonic consolidation.

Martin has shown that interstitial nephritis often accompanies or antedates the development of pulmonary tubercle. If the latter is the case, the same course of reasoning already followed in the case of the liver would indicate that the pneumogastric or phrenic paresis, on which the pulmonary lesion depends, has its origin in degeneration of the solar plexus, and that this depends on a neuritis in its renal branches. Interstitial nephritis is the nephritis of gout and of the

¹¹ Occidental Medical Times, November, 1896.

¹² Applied Anatomy of Nervous System.

¹³ Pathological Anatomy, 1886, Sect. 667.

¹⁴ Practice of Medicine, 1892, p. 442.

uric-acid diathesis, both of which depend for their production on an insufficient liver. The inquiry therefore begins with the liver and ends with the liver as an etiological factor in the production of pulmonary consumption. The acute and chronic parenchymatous forms of nephritis, so often associated with phthisis, are more likely to be induced by the passage of tuberculous toxins through the renal parenchyma.

Most persons are attacked, at one time or another, with tuberculosis, but in the majority of cases the seed fortunately falls on barren ground. "The frequency with which foci are met with in the lungs and in the bronchial glands," says Osler (*op. cit.*), "is extraordinary, and the statistics of the Paris morgue show that a considerable proportion of all persons dying of accident or by suicide presents evidences of the disease in these parts. The post-mortem statistics of hospitals show the same widespread prevalence of infection through the air-passages. Biggs reports that more than 60 per cent. of his post-mortems showed lesions of pulmonary tuberculosis. In 125 post-mortems at the Foundling Hospital, New York, the bronchial glands were tuberculous in every case. In adults, the bronchial glands may be infected while the individual is in good health."

Bartholow says that incipient phthisis is characterized by indigestion and an abnormal excretion of urea. He thus bears indirect evidence to the frequent hepatic origin of the disease. For urea is the urinary excretion of the liver cell. If this is in excess, the cell must be in a state of increased functional activity. The same condition of increased excretion of urea is found in diabetes mellitus. Indeed the increased production and excretion of urea has probably much to do with the persistence of the polyuria, for urea is nature's diuretic. When the liver has become worn and paretic from over-use, other symptoms are added to the clinical picture. The secretion of bile is deficient; hence fats are but poorly digested or absorbed in many cases and the body wastes. The leucocytes and toxins of intestinal dyspepsia fail to be neutralized on their passage through the liver, and the body at large is poisoned. Again, the glycogen-forming function is impaired.

Pary holds that one of the functions of the liver is to assimilate glucose, that is, that instead of being a sugar-producing it is a sugar-assimilating organ. The change from glucose to glycogen is apparently effected by the subtraction of a molecule of water, the formula of glucose being $C_6H_{12}O_6$, while that of glycogen is $C_6H_{10}O_5$. The failure of the liver cell to accomplish this allows the unchanged glucose to filter through into the general circulation, thus producing diabetes. It is certainly an interesting coincidence, that whereas glucose is not often found in the urine of pulmonary consumption, inosit is found.¹⁶ This substance is simply glucose plus two molecules of water ($C_6H_{12}O_6 + 2H_2O$).

To recapitulate, the seat of the tuberculous diathesis is in the pneumogastric or phrenic nerves and their connections. The causes which induce neuritis or multiple neuritis elsewhere are also operative here. Such are alcohol, syphilis, the mineral poisons, trauma, the toxins of infectious diseases and uric acid. In addition the glandular structures, and the liver in particular, in communication with these nerves, may degenerate from overwork and communicate their degen-

eration to the main sources of their nerve supply. These factors are the predisposing causes of the disease, the tillers of the soil in which the *tubercle bacillus* later takes root and grows luxuriantly.

According to this view of pulmonary consumption, treatment, to be effective, should be begun early. A diagnosis should be made of the underlying dyscrasia, and this properly treated. Success at this stage will depend much on the skill of the therapist. The diet should be most carefully regulated. It is folly to overfeed a phthisical patient. His digestion is feeble at best. Hence none but the blandest foods should be allowed. Milk, eggs, cheese, fruits, green vegetables, toasted bread, an occasional chicken or other bird, game, oysters and soft water, should compose the dietary. Substances rich in xanthin compounds, as meats, meat soups and extracts had better be avoided, as they result in the liberation of uric acid, which acts as so much poison. The ingestion of oils has long been regarded as a *sine qua non* of phthisical treatment. And if properly introduced into the system, they undoubtedly have a reconstructive action. Long experience has shown that cod-liver oil is more effective than the others. The reason for this has been much debated. If the conclusions arrived at in this inquiry are sound, most phthisical patients have a deficiency of bile. Hence their absorption of fats from the intestinal canal is attended with difficulty. Cod-liver oil, on the contrary, furnishes its own bile and is therefore more easy of assimilation. Oils may also be introduced through the skin by inunction, and as they nourish the nerves and so many of these terminate in the skin, much good can be accomplished in this way. The common habit of greasing the throats and chests of persons afflicted with inflammatory disorders of these parts is an illustration of this principle. The workers in woollen mills, particularly in the "feeding" room, enjoy a singular immunity from consumption and scrofula, and as their clothing and persons became saturated with oil the greater part of the time, it is supposed this has much to do with their health. Vaseline or cocoanut oil are the most elegant substances to use for inunction purposes.

Closely connected with the choice of foods is the use of nascent oxygen. The writer has seen striking results from its use in all stages of the disease and has witnessed several cures. It is well known that phthisical patients often derive astonishing benefit from living out of doors and especially from sleeping out of doors. Neither fever, sweating nor debility contraindicate it. Hirschfelder's contention has already been alluded to, namely, that autotoxins developed within the body are simply oxidized toxins. If this is so, and there is clinical evidence in support of the view, it is easy to understand why the fresh air treatment of phthisis is often curative. The atmospheric oxygen combines with the toxins of tuberculosis to form antitoxins, and these in turn kill the bacilli. Hirschfelder oxidizes the toxins outside the body and then injects the antitoxine hypodermically. Good results are reported of this method of treatment. Nature, however, appears to oxidize the toxins within the body.

In giving oxygen by inhalation, the writer uses a strong solution of hydrogen peroxide, mixed with glycerine in a specially constructed atomizer, and under a pressure of twenty pounds. The patient spends five or ten minutes four times a day in breathing this compound. Where there are cavities in the

¹⁶ Tyson: Exam. of Urine, 1891, p. 103.

lungs the peroxide undoubtedly exercises locally, its well-known cleansing and antiseptic properties. Again, where oxygen is given through its normal channel, the lungs, such of it as is not used in oxidizing the toxins, is directly available for systemic purposes, thus burning up within the body, the waste products of metabolism.

Finally, the suggestion of Tidey¹⁶ to strap the chest walls in phthisis, is an excellent one, and is a great relief to the patient.

Clinical Department.

A CASE OF NEPHRECTOMY FOR RENAL ABSCESS, CALCULOUS PYELITIS, AND CHOLECYSTOTOMY IN THE SAME PATIENT: RECOVERY.

BY JOHN HOMANS, M.D., BOSTON.

MRS. M., age forty-two, was brought to me in May, 1897, by Dr. Dibble of St. Stephens, N. B. She was a pale, spare woman, who had suffered from pain and dyspeptic symptoms for sixteen years. At times she had vomited; had never been jaundiced. A tumor in the right iliac region had been discovered thirteen years before I saw her. Her most pronounced and prominent symptoms were a tumor in the right lumbar region, much pus in the urine, pain and debility. The abdomen was enlarged between the umbilicus, right ribs and anterior iliac spine. This enlargement was formed by a fluctuating, lobulated, cystic tumor about the size of a man's head, which was freely movable. It was flat on percussion and seemed to be the right kidney enlarged. The left kidney, of normal shape and size, was felt in the left lumbar region. The urine contained much pus, an excess of epithelial cells, a few hyaline and coarsely granular casts with occasional oil drops adherent.

I recommended immediate nephrectomy. It seemed needless to watch the openings of the ureters into the bladder with the endoscope, because the tumor must be removed to cure the patient, and it was more than probable that the greater part of the pus came from the right kidney.

Prof. J. C. Warren saw the patient also, and concurred in my recommendation for an operation. On June 1st I operated at St. Margaret's Home. Professor Warren, Dr. Dibble and Dr. Pease were present.

An incision was made over the tumor, near the right linea semilunaris, about six inches long. On opening the abdomen the tumor could be seen under the posterior layer of the peritoneum, moving with the respiration. The posterior peritoneal fold was nicked and then torn with the fingers. The capsule was peeled away without difficulty till the pedicle, that is, the blood-vessels and ureter, were reached. There was very little bleeding. The veins, about the size of the thumb, and the artery, about the size of a slate pencil, were clearly seen, and were tied separately with silk. The ureter below was tied with the artery and vein, *en masse*, in a Staffordshire knot, and the tumor was cut away. No pus was seen in the ureter.

Great care was taken not to tear the renal veins and not to open the kidney, which was evidently full of fluid. The kidney had been removed intact; not a

drop of pus had been spilled. No shock was noticed during the removal of the kidney.

Having the dyspeptic symptoms and epigastric pain in mind, I now looked at the gall-bladder, and found it much distended and filled with gall-stones. Several ounces of straw-colored fluid were withdrawn by aspiration, and later the gall-bladder was incised. A dozen stones, of different sizes and faceted, were removed. Two were very large: one, an inch and a half long and nearly an inch thick, was firmly impacted in the common duct, and could not be dislodged until it was squeezed upwards towards the fundus of the gall-bladder with considerable force by means of the fingers and thumb in the abdomen on the outside of the duct, and at the same time the fingers within the gall-bladder skinned the walls of the duct back and off from the stone. The gall-bladder was united to the peritoneum by six fine silk sutures; the ends of these sutures were left very long, so that the knots could be cut later and the stitches entirely removed.

This proceeding of removing the sutures which have united the gall-bladder to the peritoneum, or fascia, is very important. In a recent case gall-stones formed again around sutures, and were removed, of quite a large size, twenty months after a successful cholecystotomy.¹ Some operators use catgut which is probably absorbed, but I never have confidence in the aseptic qualities of catgut or animal tendon and always use fine silk in all my aseptic work.

The renal tumor was about ten inches long; the kidney was dilated, full of pus and friable stones which had been united in a coral shape before the tumor was opened. There was more than a pint of foul-smelling pus and many stones.

The kidney was given to Dr. J. H. Wright, as were also culture-tubes taken when the kidney was opened. The bacteriological report of Dr. J. H. Wright of the Massachusetts General Hospital Laboratory is as follows: "June 3d. Tubes marked 'kidney': one sterile, the other shows a few unknown cocci. Tube marked 'from cavity after opening': a few bacilli. Two unmarked tubes sterile. A guinea-pig has been inoculated with a piece of the kidney to test for tuberculosis."

July 12, 1897.

Kidney removed by Dr. Homans June 1st, and sent to this laboratory June 2d for examination as to whether lesions of tuberculosis were present. Microscopic examination shows no evidence of tuberculosis; the kidney tissue is largely replaced by connective tissue. A guinea-pig inoculated with a piece of the specimen was killed to-day. The autopsy showed no lesions of tuberculosis.

J. H. WRIGHT.

Recovery was uninterrupted. In the first twenty-four hours thirty ounces of urine were passed, showing that the left kidney was doing its work well. The bladder was washed out once. In the second twenty-four hours thirty-six ounces of urine, perfectly clear, were passed, showing that the pus had come wholly from the right kidney. Her diet was almost unrestricted. The gall-bladder stitches were all taken out on the 6th of June. On the 9th of June the amount of urine in twenty-four hours was sixty-two ounces, and after that from forty-five to fifty. On June 22d, three weeks after operation, she went home, perfectly well, free from pain and having gained in weight.

Medical Progress.

RECENT PROGRESS IN GYNECOLOGY.

BY EDWARD REYNOLDS, M.D.

A METHOD OF UNTYING THE KNOTS OF SILK LIGATURES.¹

THE well-known disadvantages of the removal of the silk ligatures applied in vaginal hysterectomy by mere traction upon them after they have become loosened by suppuration has led to the invention by Dr. Grad of a most ingenious method of untying such ligatures by the insertion within them of a series of so-called traction strings. Each traction string consists of a piece of braided silk about 20 inches long with its two ends tied together. Three of these are used, and are distinguished by placing upon their ends one, two and three knots respectively. When the ligature has been placed in position, and is about to be tied, one of its free ends is passed through the looped end of the first traction string. The first portion of the knot is then tied in the ordinary manner, but before the second part of the knot is tied one of the free ends is passed through the loop of the second traction string. The knot is then completed in the usual manner, and if for the sake of safety a third loop is to be tied, the third traction string is arranged upon one of the free ends of the ligature before the third loop is placed. One end of the ligature is then cut short, the other is left long for traction and is fastened into a bundle with the three traction strings by tying a small bit of silk about them. This process is repeated with each ligature, and the bundle of silk thus made is sufficiently large to provide for drainage of the tissues. When the knots are to be untied, the thread binding one of the bundles is cut, and the traction string attached to the lower portion of the knot is picked up and slowly sawed backwards and forwards by alternate pulls upon these two ends. This speedily unties the part of the knot last fastened, and this traction string is then released and comes away. The second and third parts of the knots are equally readily released by to-and-fro pulls upon the appropriate traction strings. The ligature is then completely untied, and is of course removed by pulling upon its long end. The writer reports three successful cases. (The reporter is able to add a fourth in which the device was admirably efficient.)

VAGINAL LIGATION OF THE UTERINE ARTERIES FOR FIBROIDS OF THE UTERUS.

Goelet² takes up this operation, which he has previously advocated, to give the results of a riper experience with it. He still strongly advocates the operation, but restricts it to interstitial growths that have not extended beyond the level of the umbilicus, and to small superperitoneal growths which spring from the wall of the uterus below the fundus, and are without extensive adhesions through which the tumor may obtain nourishment. He has not seen a tumor completely disappear after the operation, but has uniformly seen a decrease in the size of the tumor, and the disappearance of symptoms. He insists upon the necessity of dividing the artery between the ligatures in order to secure its complete obliteration. The technique of his operation is as follows: The preparation of the vulva

and vagina is as careful as for vaginal hysterectomy. The cervix is dilated, the uterine cavity is thoroughly curetted, washed out, and packed with iodoform gauze. A traction ligature is then inserted through both lips of the cervix. With this the uterus is drawn down and over to one side, so as to expose the left vaginal vault. A semicircular incision, about an inch and a half long, is made through the vaginal wall at the cervico vaginal junction to the left of the cervix. With the index fingers the vaginal tissue is carefully separated from the broad ligaments at the anterior angle of the incision, which frees the bladder and pushes the ureter to one side, out of reach. Posteriorly, the broad ligament is carefully separated in the same manner without penetrating the peritoneum. By passing one finger in front and the other behind, the base of the broad ligament is grasped between them, and the pulsation of the uterine artery can be felt. It is carefully isolated, seized with a broad ligament clamp and drawn down. A curved aneurism needle, carrying a stout catgut ligature, is passed up along the finger as a guide and around the artery to the outer side of the clamp and tied. A second ligature is passed around the artery nearer the uterus to the inner side of the clamp, and when this is tied the clamp is removed and the artery is divided between them.

The cervix is now drawn over to the opposite side, and the same manœuvre is repeated on the right side. The wounds are now irrigated with a one-per-cent. solution of lysol, and the vaginal incisions are closed with a continuous catgut suture. The vagina is packed loosely with iodoform gauze, which is renewed after forty-eight hours. The operation is done with the patient on the back in the lithotomy position. A broad periueal retractor with a short blade is used. Sometimes a narrow-bladed lateral retractor is employed, being inserted through the vaginal incision to hold the ureter to one side.

The needle which he employs for carrying the ligature around the artery is one of special design, and is made for him by Messrs. J. Reynder & Co. It is set at a more obtuse angle to the shaft than those ordinarily made, and the point is semisharp instead of blunt, but it is not sharp enough to wound the artery.

The patient is confined to bed for ten days or two weeks. There is usually no elevation of temperature following the operation, and the wounds heal promptly if strict asepsis has been preserved throughout.

SKIAGRAPHING A FOREIGN BODY IN THE PELVIS.

Cordier³ describes the skiagraphing of the contents of the pelvis by the introduction of sensitized photographic plates into the vagina of the female, and the rectum of the male, and also describes the use of a fluoroscope made in the shape of a Fergusson's cylindrical speculum. A highly sensitized photographic plate is cut into pieces from 1½ to 2½ inches wide and 6 inches long. This plate is wrapped in heavy black paper to protect it from the sunlight, the film side of the plate being carefully marked, as the x-rays do not penetrate glass well. The plate may be inserted by anointing it with vaseline or soap, or by covering it with a rubber condom, but great care must be exercised in the use of soap, as it will ruin the plate if allowed to come in contact with it. The patient is placed in the dorsal position with the spine somewhat flexed. The photographic plate is introduced into the vagina

¹ Grad: American Gynecological and Obstetrical Journal, vol. x, No. 2, February, 1897.

² Loc. cit.

³ American Journal of Obstetrics, vol. xxxvi, No. 2, August, 1897.

with the film side to the front and passed as high as possible. The Crookes tube is then so placed that its centre of effort will be directed somewhat in front of the axis of the superior strait. The writer publishes a skiagraph which shows the pubic ramus and a number of foreign bodies which have been introduced into the bladder. He hopes to be able by means of it to detect not only the presence of foreign bodies but to obtain an outline of the uterus.

A CASE OF VARICOSE VEIN OF THE BROAD LIGAMENT.

Baldy⁴ reports a case in which he made an exploratory incision to determine the source of pelvic pain which had resisted three years of treatment, and for which no adequate cause could be found previous to operation. Upon looking at the organs with the patient in the Trendelenburg position, they appeared wholly normal, with the exception of a varicosity of the vessels of the left broad ligament. These were multiplied in number from six- to ten-fold, were much increased in size, and greatly thickened. The Fallopian tube, ovary and broad ligament of that side were excised as widely as possible. The case is reported shortly after the operation, but the woman was so far relieved from pain. The writer reports the case on account of its rarity and with a full recognition of the fact that the necessity of operating upon varicosities in the pelvis is much doubted by the profession.

THE SURGICAL TECHNIQUE OF OPERATIONS FOR PUS IN THE PELVIS.

Stone⁵ describes a method of enucleation of large pus tubes without rupture and consequently without spilling their contents into the peritoneum, which seems so reasonable and for which he claims such an extraordinary success, that a large portion of his description of the technique is quoted:

"Given a patient in sufficiently good condition to bear an operation of one hour in duration, who has a clinical history and symptoms enabling us to make a diagnosis of pyosalpinx and ovarian abscess, single or double. The uterus is fixed, the whole pelvis filled, not as some say, with 'exudate,' but with tubes and probably ovaries converted into pus sacs and held firmly by adhesions to uterine ligaments, abdominal and pelvic walls, and perhaps intestine, omentum and mesentery. The abdomen is opened at once by an incision four or five inches in length between the umbilicus and pubes. Omental adhesions, if present, are tied off, and, if possible, immediately separated and fragments removed, although this is often at first impossible. The next step is to find one of the uterine cornua, not merely as a landmark, but in order to clamp the tube and broad ligament as closely to it as possible, and at once prevent any or all hemorrhage during the subsequent steps of the operation. The ovarian arteries are, if easily seen or located, also clamped and tied. It may be seen that the purpose in view thus far is to save every possible drop of blood. Formerly a few ounces of blood lost during these operations was thought of but little consequence, but we are no longer of this opinion. If intestinal adhesions have rendered access to the uterine cornua difficult, they must be overcome and separation completed far enough to permit inspection of the underlying tube and ovary, or at least

the upper portions thereof. The tube is cut just outside the clamp nearest the uterus, and separated throughout its entire length from the meso-salpinx, which, of course, means section of the upper border of the broad ligament. It is generally possible to insert the finger between the ovary and uterus first, then to separate tube and ovary from the broad ligament. The fimbria attaches itself to the ovary most frequently on the outer side, and rupture of the pus sac is known to occur here in most instances; therefore the specimen must be carefully handled to avoid rupture at this point. Quite often rupture unnecessarily occurs deep down behind the uterus, when the surgeon fears penetration of the bowel. The plan of separating the anterior surface first works especially well when the tube or ovary is known to be very firmly attached to the bowel, and every care must be exercised to avoid a rent of the intestine.

"It is a pleasant surprise, to those who first try this plan, to see how much more room is made for manipulation and how readily the specimen comes up. It is better to use vision, to take more time, and to attack these distended tubes and ovaries from every or any point of vantage, rather than be obliged to close a tear in any portion of intestine. The writer asserts that every tear of the bowel in these operations is a mistake or a misfortune and should be prevented. He does not say that communications do not exist between abscess and bowel, for he has found and closed these openings; nor does he say the bowel is not so necrotic at times as to require immediate repair. But one does not make such a rent—it is already existing; and, moreover, he should see and know just what he is doing when he is enucleating such a specimen. It should be set down as an error when the surgeon tears into comparatively healthy bowel. Of course the peritoneal coat is often injured and requires repair; but reference is here made to complete tears into the lumen of the intestine."

He suggests further that it may be possible to save some infected tubes by the injection of an antiseptic solution into the cervix during the operation, with sufficient force to expel a minute stream of it through the tubes where it can be caught by a sponge without allowing it to come in contact with the contents of the abdomen. He quotes cases in which, after disinfecting acutely purulent tubes by this method, he has closed the abdomen without drainage, and seen the patient return to health.

THE TECHNIQUE OF CÆSAREAN SECTION.

Barton Cooke Hirst⁶ summarizes the technique to which his experience of fourteen Cæsarean sections has led him to settle down. He opens the abdominal cavity by a sweeping incision through the wall, trusting to the absence of intestines in front of the uterus. This incision is rapidly enlarged to a degree which permits the delivery of the uterus from the abdomen. An incision an inch long is then made through the uterine muscle; next, in Hirst's own words, "with one rapid movement of the left hand and arm the uterine wall is torn down to the internal os, the membranes are ruptured, the placenta, if in the way, is detached and pushed aside, the child is seized by the most accessible part—shoulder or leg—is delivered, and with the placenta still attached to it handed to an assistant. So far the operation rarely requires seventy-five seconds. Then

⁴ American Journal of Obstetrics, vol. xxxvi, No. 3, September, 1897.

⁵ Loc. cit., vol. xxxvi, No. 3, September, 1897.

⁶ Loc. cit., vol. xxxv, January, 1897.

follows an easy hysterectomy; ligation of the ovarian arteries and of the arteries of the round ligament; application of clamps; cutting of the broad ligaments; preparation of peritoneal flaps; amputation of the womb; ligation of the uterine arteries, and over-sewing of the stump, which is dropped."

NOTES ON THE DIAGNOSIS AND TREATMENT OF THE FEMALE URINARY ORGANS.

Skene⁷ after emphasizing the importance of a study of symptomatology, speaks of the advantages of the galvano cautery in treating morbid growths and ulcerating tissues of the bladder. He praises the ease with which its action can be limited to the diseased tissue, and the manner in which the eschar protects the tissues from contact with the urine. He also describes a method of destroying neoplasms by seizing their pedicles with a specially devised forceps clamp and then devitalizing the tissue of the pedicle by the application of a dessicating degree of electric heat. He reaffirms his belief in the value of the operation prescribed by him a number of years ago for the relief of cystocele, which consists of making a small buttonhole incision through the vaginal wall at the junction of the urethra and bladder; a probe is then passed upward between the vaginal wall and bladder to the cervix uteri; this is followed by a closed forceps which is extended within the tissues thus making an extensive submucous separation between the vagina and bladder. The mucous membrane of the bladder is then held out of the way with the probe while the raw surfaces beneath the vaginal mucous membrane are brought together by through and through stitches, thus taking a tuck in the end of the anterior vaginal wall. He further notes several interesting cases in which when a ureter was divided during hysterectomy and the bladder at the same time opened, spontaneous cure and closure of the resulting fistula followed.

A NEW METHOD OF OBTAINING THE URINE SEPARATELY FROM THE KIDNEYS IN WOMEN.

Rose⁸ criticises the various methods so far in vogue and recommends a new one, which, he says, has the following advantages: great certainty, simplicity of instrumentarium, avoidance of infection of one ureter from the other, avoidance of anesthesia. Rose employs a speculum one finger long, with a lumen of about one centimetre; this is introduced into the bladder, after previously immunizing the urethra, for a distance of five and a half centimetres, and is placed directly upon the ureteral opening. Its principle, therefore, consists of a direct elongation of the ureter. Pelvic elevation or the genupectoral position is used. The practicability of the method has been demonstrated upon the cadaver and living subject.

BICYCLING FOR WOMEN.

Theillhaber⁹ recommends cycling in cases of amenorrhea, especially when the uterus is undeveloped. Dysmenorrhea of nervous origin in young girls and sterile women is often relieved. In endometritis the writer has seen no results, either favorable or unfavorable, from this form of exercise; in the hemorrhagic form he advises against it on theoretical grounds. It should be forbidden in chronic as well as in acute

gonorrhoea, in salpingitis, and in subacute and chronic peritonitis of whatsoever origin.

Flexions and versions do not constitute a contra-indication; in fact, cycling is often recommended for patients with these conditions with the view of relieving nervous symptoms and strengthening flabby muscles rather than actually relieving the displacement. This may account for the good results claimed in some cases of partial prolapsus.

The use of the bicycle is inadmissible by patients with fibroid and ovarian tumors. The writer notes the rapid increase in size of fibroids in two women who rode contrary to his advice. Bladder troubles are usually aggravated by cycling, though on this point there is some difference of opinion. Hemorrhoids are sometimes relieved, but are sometimes made worse, especially when improper saddles are used. Such benefit as may be experienced is usually due to the relief of constipation. Women ought not to ride during menstruation, though the writer admits that several of his patients had done so without injury. Pregnancy is a positive contraindication. Two of the patients who disobeyed his injunction aborted, but a third went on to full term, though she had a retroflexed uterus and prolapsed ovaries.

In general, he approves of cycling in moderation.

II. Macnaughton Jones¹⁰ calls attention to the fact that cycling may have an injurious effect on women at the time of the menopause, and should not be indulged in except on the advice of a physician, especially if the patient is anemic and has functional cardiac trouble. He doubts the propriety of women with retrodisplacements of the uterus riding, with or without pessaries; this applies especially to anemic young girls. Hemorrhoids are aggravated, and coccygodynia may result.

The writer recommends a pneumatic saddle so constructed as to support the ischia, but not to press upon the external genitals or the coccyx; there should be no projection under the pubes. He approves highly of this form of exercise, which he regards as far superior to massage.

Flccl¹¹ says bicycling exerts a favorable influence in all cases where the uterine disorders are due to a relaxed condition of the parts. In chronic inflammatory conditions, it may be indulged in with care and moderation, but must be interdicted in all acute cases. Great benefit is derived from cycling in lack of appetite, chronic constipation, sleeplessness and general malaise—in fact, in all disorders due to insufficient exercise. The patients should not feel discouraged if improvement is not rapid or is even preceded by an aggravation of symptoms. It has a valuable influence in disordered menstruation, especially in amenorrhea and dysmenorrhea. Anemic, badly-nourished women gain in weight, while those who have a superabundance of fat are apt to lose. It is the physician's duty to draw attention to proper dressing before permitting active exercise. A corset should not be worn, as it interferes with respiration.

ETIOLOGY AND TREATMENT OF CANCER OF THE UTERUS.

Baecker¹² from an analysis of 705 cases of cancer of the uterus, arrives at the following conclusions with reference to the etiology of the disease:

(1) The true origin of malignant disease of the

uterus is as yet unknown, nor can it be referred to a specific micro-organism.

(2) The indirect cause is endometritis, generally of puerperal origin, which furnishes a suitable nidus for its development. This is shown by the fact that cancer is common in women who have borne children, while it is comparatively rare in single and in sterile women, as well as in those who have had gonorrhea. Moreover, in nearly every case of cancer there is a chronic catarrh of the endometrium. Endometritis is the primary condition, malignant degeneration being secondary. Hence the practical importance of treating endometritis actively from the outset as a prophylactic measure.

In the treatment of carcinoma of the cervix total extirpation is always preferable to high amputation, because in leaving behind the body of the uterus the surgeon leaves a chronic endometritis which furnishes a favorable nidus for the development of malignant disease, even if the latter is not already present.

HYPERTROPHY OF THE CERVIX UTERI IN A VIRGIN.

Helme¹³ describes a case of hypertrophy of the cervix in an unmarried woman, aged twenty-one years. The fundus uteri was at nearly its normal level, while the cervix protruded from the vulva, a sound passing to the depth of four and one-half inches.

The following operation was performed: a circular incision was carried around the cervix at the level of the vesical attachment, and lateral incisions were made on either side parallel with the bases of the broad ligaments. The cervix was then freed as in the preliminary step of vaginal hysterectomy and both uterine arteries (including the cervical branches) were ligated, in order to cut off the blood supply from the hypertrophied part. The cervix was drawn forcibly downward and transfixed antero-posteriorly with siver wire. Circular amputation was performed, followed by bilateral section of the cervix, forming anterior and posterior flaps. The vaginal and cervical mucous membrane were united, and lastly the cervix was sutured to the edge of the vaginal wound on either side.

The stitches were removed on the ninth day and the patient was discharged at the end of the third week. When examined six weeks after the operation the canal was patent and the uterus measured two and three-quarters inches.

THE USE OF STEAM WITHIN THE UTERINE CAVITY.

Pitha¹⁴ reports the results of his observations in Pawlik's clinic, extending over two years and including 46 patients. The deductions are also based on examinations of six uteri removed from four to fourteen days after the application of steam.

The technique is quite simple: A small kettle, fitted with a thermometer, is connected with a double-current uterine catheter by means of rubber tubing; a wooden handle on the instrument protects the hand of the operator. The temperature is raised to 105°-115° C., and after the steam issues from the holes in the catheter the instrument is cooled to avoid burning the vagina, and is then introduced into the uterine cavity. The steam is then allowed to escape for one minute. It condenses within the uterine cavity, where its action is really due to the heat from the catheter and the hot

water. Narcosis is not necessary, as most of the patients bear the application easily. Active uterine contractions followed, and in some cases were quite violent, attended with reflex vomiting, but there were no other unpleasant consequences. Sloughing occurred, and was not completed before the fourteenth day, the endometrium not being entirely regenerated until four weeks had elapsed, showing that the cauterizing effect was quite as profound as after the use of the Paquelin. Twenty-eight patients, with hemorrhagic endometritis, treated in this manner were discharged cured, and ten with hemorrhage following abortion; in the latter, decidua remains were first removed with the curette before applying the steam.

The use of this agent is also highly recommended in cases of malignant diseases of the corpus uteri.

The advantages claimed for this method of intra-uterine cauterization are the ease and rapidity with which it can be effected in a clinic, the immediate hemostatic effect, and the deep slough which is caused, as well as the freedom from untoward results. The after-treatment is simple. The patient is kept in bed until the slough has entirely separated, the vagina being irrigated and tamponed lightly with iodoform gauze. No intrauterine injections are given. Among the disadvantages the writer mentions the unequal character of the cauterization and the fact that the after-treatment is more prolonged than after curettement. He is not willing to assert that "vaporization" is preferable to the latter operation.

DESTRUCTION OF THE ENDOMETRIUM BY HOT INJECTIONS.

Schick¹⁵ discusses the value of various methods of removing the diseased endometrium. The ideal method, he believes, should fulfil the following requirements: (1) absolute asepsis; (2) removal of the entire tissues down to the muscular layer; (3) thorough removal, so that no portion of the mucosa may remain; (4) limitation of the destruction action, so that extensive injuries to the deeper parts may be avoided.

None of the procedures usually adopted satisfies these requirements. In curettement the diseased mucosa is rarely completely removed, and then only in puerperal cases. Chemical agents, especially chloride of zinc, may cause destruction of the subjacent muscular tissue in some spots, while in others islands of mucous membrane remain untouched. Electrolysis produces the same results as caustics, though less effectively.

The writer, after various experiments, came to the conclusion that the effect of hot water was most satisfactory. Before employing it in the living subject he studied its action upon the endometrium in freshly extirpated uteri. Water at a temperature of 80° to 85° C. was allowed to flow through an intrauterine catheter for periods ranging from thirty seconds to two minutes. After half a minute the entire mucosa was seen to be covered with a thin, whitish layer, which penetrated more deeply according to the length of exposure to the action of the hot water. As practised on the living subject the writer's technique was as follows: The cervical canal is dilated with laminaria tents until it admits the little finger. The patient is anesthetized, the genitals rendered thoroughly aseptic, and the cervix is seized and drawn down with a volsella. To a kettle of water, heated by a Bunsen burner, is attached a rubber tube on which is fitted a Bozeman-Fritsch

¹³ British Medical Journal, December 26, 1896.

¹⁴ Centralblatt für Gynäkologie, No. 22, 1897.

¹⁵ Centralblatt für Gynäkologie, No. 23, 1897.

double-current catheter. A second tube communicates with a receptacle filled with ice-water, which is allowed to flow into the vagina before and during the operation. The hot water is now allowed to enter the uterus while the end of the catheter is constantly turned in different directions in order that the entire endometrium may be affected. As the hot water escapes from the os it mingles with the cold, and thus does not burn the vagina. Since the action of the heat is more intense upon living than upon dead tissues, the writer adds the caution that thirty seconds should be the limit of exposure. The degree of reaction is noted by the marked contraction of the uterus.

Several successful cases of menorrhagia are reported (including two cases of abortion and one of fibromyoma), in none of which were any unpleasant effects observed.

The writer calls attention to the different actions of steam and hot water. The former has been introduced into the uterus for the purpose of controlling hemorrhage, while the effect of the latter is to destroy the entire lining membrane of the organ. While the writer has seen no failure of the mucosa to become regenerated when it is exposed to the action of the heat for half a minute, he thinks it wiser, until the subject has been more fully studied, to employ it only in the case of women with fibroids and those who are near the climacteric, in whom the preservation of the function of menstruation would be less important.

INTRAUTERINE INJECTIONS.

Dölerle¹⁶ reports the results of experimental injections of methyl-violet, iodine, and chloride-of-zinc solutions in six cases in which he was about to perform total extirpation of the uterus. The usual cautions were employed—thorough dilatation of the cervical canal, moderate force, and the maintenance of a return current, yet in all but one instance (a case of endometritis fungosa) the fluid entered the tubes and was forced into the peritoneal cavity. The writer infers that the result of these experiments throws considerable light upon the question of tubal menstruation and the extension of gonorrheal infection. It is unnecessary, he says, to add that the fact of this perviousness of the tubes to fluids should lead to the greatest care in regard to intrauterine therapeutics.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE. SECTION ON OBSTETRICS AND GYNECOLOGY.

STATED Meeting, October 7, 1897, the PRESIDENT, EDWARD G. JANEWAY, in the chair.

THE TREATMENT OF PUERPERAL SEPTIC DISEASES.

The medical aspect of the subject was presented in a paper by DR. CHARLES P. JEWETT, of Brooklyn. This class of affections, he said, was strictly among the preventable diseases, and the accoucheur was usually responsible for their occurrence. Prophylaxis must begin many weeks before the time of labor, and among the predisposing causes to which he referred were anemia, syphilis, vaginal disease, diarrhea, constipation and auto-intoxication from the retention of excrementitious products in the system. It was the

opprobrium of the profession that, notwithstanding all the advances which have been made in the last few years, the percentage of deaths among practitioners in general still remained undiminished.

He condemned the use of the douche after parturition, except in rare instances, as interfering with the normal processes, in which the parts were protected by the natural secretions. In order to treat any case intelligently an accurate diagnosis was required, and he advised a vaginal examination by the speculum. Any lacerations could then be packed, or otherwise treated, and if there were foul discharges a vaginal injection with peroxide of hydrogen or Labarracque's solution (1 to 10) should be made by the physician himself. No interference should be made with the uterine cavity unless it were positively known that this was affected. In exploring the cavity it was difficult to render the hand aseptic, and he thought the curette preferable, though curettage should never be lightly undertaken. For scraping the cornua, a special form of instrument was required. In the absence of *débris* in the uterus, the use of the curette was contraindicated. Under these circumstances the cavity might be painted with iodine or packed with an iodoform dressing. Intrauterine irrigation was permissible only so long as it was followed by a reduction of the temperature. The injection of steam at a temperature of 100° C. had been used with favorable results in France.

In the systemic treatment, eliminants and tonics, such as strychnia and quinine (not in large antipyretic doses), were called for. Also concentrated liquid nourishment and, in many cases, alcoholic stimulants in large quantities. The free use of water internally and externally in the form of cold bathing or sponging was often of great service. Plenty of fresh air was essential, and the intravenous injection of saline solutions had been employed with success. Ergot was thought to be useful in limiting the diffusion of the poison. The antitoxic serum treatment was as yet under trial, and no very definite conclusions could be made in regard to it at the present time. He had employed it in six cases, but in one only had the results appeared to be satisfactory. Nuclein he had used in three cases, but with no result. Dr. Jewett's general conclusion was that, while of late years much had been added to our knowledge of prophylaxis, but little progress had been made in the medical treatment of puerperal sepsis.

DR. EGBERT H. GRANDIN read a paper presenting the surgical aspect of the subject. It was very important, he thought, to determine in any case under observation whether we were dealing with sapremia or septicemia. These conditions were very different, although, if allowed to go undisturbed, the former was apt to result in the latter. Curetting was liable to do injury, unless practised with great care, by breaking down the protecting bed of leucocytes which nature provided and thus causing a further extension of the trouble. We had, then, a putrid and a septic endometritis. The best means of diagnosis was the accoucheur's fingers. If any remains were found in the uterus, the curette was to be employed, but if there was nothing to remove, curetting should not be resorted to. He had found it advantageous to use sterile gauze to keep the cavity open. It should be removed in about thirty hours. Iodoform gauze was attended with considerable danger and he had rejected it.

¹⁶ Centralblatt für Gynäkologie, No. 25, 1897.

As to the use of the curette, the dull instrument was quite sufficient to remove necrotic tissue, but either the sharp or the dull curette was dangerous in inexperienced hands.

In septic forms of endometritis, he thought the less interference the better, as over-action was apt to cause a diffusion of the poison into the tubes, ovaries and peritoneum. His own practice was to employ, after one injection, sterile gauze soaked in absolute alcohol. As to the matter of operation, it was a question not so much *how* as *when*. All inflammatory processes were modified by the puerperal condition, and the great aim should be to act before systemic infection was deep. When this was the case operation availed but little. In puerperal surgery he was the best judge who had for years made a study of the process of parturition, and not the general surgeon. Here, plastic peritonitis and cellulitis was apt to become septic, but in certain cases it was advisable to anesthetize the patient and make an incision. As a rule, there were multiple septic foci, and the question of the justifiability of hysterectomy was as yet in an unsettled state. In this connection he mentioned the case of a woman, with multiple abscesses of the uterus, who recovered without operation and afterwards gave birth to a child.

General septic peritonitis was the *bête noir* of the surgeon and particularly so when it was associated with the puerperal state. The septic condition rapidly affected the nervous centres and almost always proved fatal. When the peritonitis was plastic the prognosis was less grave. It was in cases of the latter kind that opium proved of so much service. As long as a part of the peritoneum remained unaffected, however, there was a chance of success.

DR. W. A. N. DORLAND, of Philadelphia, spoke of the use of the serum treatment in his own city, and said that thus far it had not proved very satisfactory. At a meeting held some little time ago twelve cases were reported by various physicians and in six of them the patients died. In four cases the treatment seemed to be successful, and in the other two the matter was doubtful. In the experience of Philadelphia physicians since then about one-half of the cases had also died. From this 50 per cent. mortality it might perhaps be inferred that the treatment was positively harmful; but, on the other hand, it was no doubt true that the cases in which it was employed were of more than ordinary severity. Personally, he should not be inclined to resort to it unless an exact bacteriological examination showed the presence of the streptococcus. Even if there was pus in the lochia, it did not necessarily follow that it was in the system at large.

There were two points on which he wished to lay stress: (1) the importance of resorting to anesthesia in making a diagnosis, and (2) the fact that this class of patients was much more apt to recover with intact organs than patients in the non-puerperal state. Therefore, great care should be observed as to the excision of organs. The absorption of products was very remarkable, even in cases where there were the most extensive exudates. Hence, a judicious conservation was all-important, and even though both tubes and ovaries could not be saved by drainage, he thought drainage better than excision. Another point was the importance of limiting the time of intrauterine injections or irrigation. If continued for more than one or two days, they did more harm than good. He be-

lieved intravenous injections of saline solutions to be of great service.

DR. P. F. MUNDÉ said that he had been much gratified by the conservative stand taken by the previous speakers as regards surgical interference. He had always been satisfied to keep the patient alive by combating high temperature and maintaining nutrition in every possible way, until the system could throw off the poison. Only within the last year had there appeared a ray of hope for a more successful treatment. He had recently treated two cases which he thought would certainly prove fatal with antitoxic serum, and both recovered. Whether this result was positively due to the serum he could not say; but at all events the gratifying fact remained that the patients got well. What we wanted now was more scientific reports regarding this subject. In regard to surgical interference, he was glad to hear it said that the curette was not to be used unless there was something to be removed by it. When there was no septic product to be removed he thought it was a mistake to employ the instrument, no matter how thick the inflamed endometrium, as it only served to open new channels for septic infection. Wherever pus pointed, it should be evacuated; but he did not believe in removing the uterus when the patient was in such bad condition that the operation was almost sure to prove fatal. In puerperal peritonitis he believed in incisions. It was true that the results were usually bad, but still a few patients recovered.

DR. H. C. COE said that the history of the treatment of endometritis was very much like that of abdominal surgery. In its first stage operators were too timid, in the second, too bold, and then there had come a time when a middle ground was occupied. As Dr. Grandin had stated, the first thing to do was to locate the trouble by anesthetizing the patient and making an exploration with the finger. He wished to call attention to one important point, namely, that imperfect drainage is not infrequently due to ante-flexion, and that the mere opening up of the canal was sometimes followed by the best results. As regards operative measures, he would recall the advice of Dr. Lusk, "You must not stir up a sloughing uterus." He had not seen a case of recovery after hysterectomy or radical operation for suppurative peritonitis. Locally, he was very partial to the use of peroxide of hydrogen, and in the way of general treatment thought well of the intravenous injection of saline solutions. The inhalation of oxygen had also proved of service in his experience, and he had sometimes kept it up for a week at a time.

DR. C. A. VON RAMBOUR thought that the chief point in the treatment was prevention. Among 1,500 women treated in the outdoor lying-in service of the Post-Graduate School and Hospital, where the surroundings and general conditions were, as a rule, very unfavorable, there had been but two deaths, and only one of these was due to sepsis. He considered bichloride-of-mercury solutions objectionable, as liable to cause acute nephritis. When septic infection occurred the aim of the physician should be to combat multiplication of the cocci, high temperature and heart-failure. This main reliance was placed on alcohol in very large quantities and hydrotherapy. The serum treatment was as yet too new to enable us to form a positive opinion upon.

DR. H. N. VINEBERG said there was a class of cases in which the patient did well for five or six days, when

there would be a rise of temperature. The only local condition discoverable might be an enlarged uterus, and on exploration it would be found that a portion of the placenta had been left behind and was decomposing. This he was in the habit of removing with the curette and he then injected the cavity with plain water or a two-per-cent. solution of carbolic acid. He mentioned one case in which this treatment had not proved successful, and in which he was finally obliged to resort to hysterectomy, with the result of saving the patient's life.

DR. R. A. MURRAY spoke first of the advantage of a full dose of ergot after the delivery of the child.

If there was the slightest rise of temperature an examination should be made with the finger, and we could then use the curette with advantage, if this was necessary. Afterwards we could apply iodine, alcohol or other agent to close the mouths of the veins by coagula. For the reduction of temperature he thought very highly of veratrum viride, as used by Dr. Fordyce Barker and others. It was best given in small doses, frequently repeated, and in association with whiskey, which was the natural antidote to it. As to diffuse peritonitis, he had yet to see the case, at the autopsy, where he felt that an operation would have done any good. In localized peritonitis it was his practice to drain and then operate afterwards if the patient survived.

Two speakers having referred to the frequency of malaria as a complication of the puerperal state which called for large doses of quinine, DR. S. MARX, the Chairman of the Section, took up the question, "Why is the antitoxic treatment successful in surgical sepsis, and not in puerperal?" He believed the reason was because in the latter the septic condition was complicated by unknown factors incidental to the puerperal state. He had employed the serum treatment in five cases, in four of which a careful bacterial examination was made, and his experience had convinced him that the infection present was of such a nature that we had to deal not only with the streptococcus, but with some other element as yet undetermined. All the five cases proved fatal. He was of the opinion that the many favorable cases reported from abroad were in reality cases of septicemia, which would have recovered under almost any treatment.

Recent Literature.

The Essentials of Obstetrics. By CHARLES JEWETT, M.D., Professor of Obstetrics in the Long Island College Hospital, Brooklyn, N. Y. In one 12mo volume of 356 pages, with 78 illustrations and 3 colored plates. New York and Philadelphia: Lea Brothers & Co. 1897.

This book is well arranged for ready reference, being provided with a good index, and with black type headings to paragraphs. For example, under Eclampsia, the following paragraphs are given: Definition, Frequency, Etiology, Premonitory Symptoms and Signs (which are given in a table), Differential Diagnosis, Clinical Phenomena and Treatment, the latter divided into Prophylactic and Remedial—all this in a space of five pages. In this manner a cyclopedic amount of information is compressed into a very small space.

The illustrations are good and to the point.

HEALTH LEGISLATION IN GERMANY.

MANY of the Sanitary Laws in force in the German Empire are models of efficient legislation, and have proved to be the means of placing Germany among the foremost of civilized countries in matters¹ pertaining to public hygiene.

In consequence of its Vaccination Act and its thorough enforcement, Germany has a small-pox death-rate far below those of its neighboring countries. The following is the substance of the existing vaccination law:

VACCINATION LAW.

Every child, in the calendar year in which it completes its first year of life and every pupil in school in the year in which it attains the age of twelve years, must be vaccinated, unless a previous attack of small-pox provides immunity from a recurrence of the illness. Men who are liable for military service are re-vaccinated on entering the army or navy. By the appointment of vaccinating physicians,² paid from the public treasury, every one has an opportunity of obeying the vaccination law without expense. The necessary lymph is produced at vaccine establishments in each of the twenty-five larger cities of the empire, under the best scientific supervision, by well-trained experts.

This method is exactly the opposite of the method pursued in America, where vaccine lymph is mainly a commercial product, being largely prepared by poorly trained men as a source of private revenue, in such a manner as to secure the greatest pecuniary returns at the lowest cost to the producer.

FOOD LAW.

By a law of May, 1879, police-officers are authorized to take samples of food offered for sale in shops. Adulteration of food and drink, for the purpose of commercial deception, and the sale of adulterated food

¹ Gesundheitsbüchlein, bearbeitet im Kaiserlichen Gesundheitsamt, Berlin, 1896.

² Loc. cit., p. 192, Berlin.

under a description calculated to deceive, is forbidden. The manufacture or sale of food and other necessities of life which are injurious to health is forbidden and punished by severe penalties and by imprisonment in frequent cases.

Special laws provide that :

(1) Petroleum, which produces an inflammable vapor at a temperature below 60°, must be kept in vessels marked in plain letters "inflammable."³

(2) Lead, or alloys containing more than 10 per cent. of lead, must not be used in the making of cooking-utensils, and they must not be coated internally with alloys containing more than one per cent. of lead. This regulation applies to all objects which come in direct contact with the mouth or are used in preserving food.⁴

(3) Articles used in coloring food or drink must not contain the following substances: Antimony, arsenic, barium, lead, cadmium, chromium, copper, mercury, uranium, zinc, gamboge, coralline and picric acid.

The foregoing colors must not be used in the wrappings of food, in making soap, or in preparations for the skin or hair, or in the manufacture of toys.

The use of arsenical colors is forbidden in the manufacture of carpets, curtains, wall-paper, paints, furniture, artificial flowers, clothes and type.⁵

(4) The sale of imitation butter is forbidden unless distinctly labelled as such.⁶

(5) The use of machines for making artificial coffee beans is forbidden.⁷

(6) A law of April, 1892, forbids the addition of certain injurious substances to spirituous liquors.

WORKSHOPS AND FACTORIES.

Children under thirteen years must not be employed in factories, and over that age only when they have completed their school course. Children and young women must not be employed in factories declared to be dangerous to health or morality. This law has been extended to include wire-works, glass-works, sugar-refineries, rolling-mills, brick-works, coal, tin and lead mines, etc.

Children under fourteen must not be employed more than six hours a day; from fourteen to sixteen years, not over ten hours a day, work not to begin for persons at this age earlier than 5.30 A. M., nor to be continued after 8.30 P. M., and to be broken by regular intervals. These regulations apply also to females, and they cannot be employed more than eleven hours per day, for more than ten hours on Saturdays and the days before holidays. They must also have a rest of an hour at noon, to be increased to one and one-half hours if they have to attend to housework at home.

Working people are not required to work on Sundays and holidays. Most heavy labor must cease on these days, with certain exceptions. Otherwise all

workers are entitled to twenty-four hours' complete rest on Sundays and holidays, thirty-six hours if two such days are consecutive and forty-eight hours at Christmas, Easter and Whitsuntide. In the exceptions, an equivalent must be given on ordinary working⁸ days to those who are employed in these periods of rest.

COMPULSORY INSURANCE AGAINST SICKNESS, ACCIDENTS, OLD AGE AND DEATH.

All persons of both sexes, employed for pay, in trade or business (about eight millions altogether), are insured compulsorily, the premiums being paid by the employer and the employed, the former paying one-third and the latter two-thirds. Domestic servants or farm laborers are not included. Every insured person, in case of illness, receives medical attendance, medicine and other articles essential to his recovery free (for example, trusses, bandages, etc.). If unable to work, he receives at least one-half the usual wages for each working day while he is sick. These privileges continue thirteen weeks, if illness lasts as long. A sum is paid to relatives in case of death. Insurance against illness is conducted by sick clubs, each trade having one.

Insurance against accident is more common than sickness insurance. All persons (about eighteen millions) employed in industry and agriculture are subject to it, also subordinate trade officials and small contractors. All persons insured are by law thus protected against the results of accidents occurring in the course of business, even if the insured, himself, or a third party, is responsible for the accident. All sudden events connected with the industry are to be considered as accidents, not including results due to prolonged employment, such as lead and phosphorus poisoning. Compensation is guaranteed to the wounded. Such compensation includes the costs of recovery, as well as a payment for the time in which the sufferer is unable to work, to an amount not exceeding two-thirds of his average earnings in the previous year. These payments do not begin until the fourteenth week after the accident, up to which time the patient is entitled to support by reason of his insurance against sickness. If death is caused by the accident, money is paid to the relatives for burial expenses, and the widow and children receive annuities, the former till death or remarriage, the children until they are fifteen years old. The cost of accident insurance is borne entirely by the employers, who are associated for that purpose.

Incapacity for work on account of age (seventy years), but not from temporary illness or accidents protected by accident insurance, is provided for by the law, as insurance against inability to work and old age. This law applies to all laborers in all branches of trade (exclusive of apprentices and servants) and to officials⁹ and messengers earning less than five hundred dollars per year — embracing in all about twelve million persons. The advantage of this law — an annuity vary-

ing according to wages and number of years the person has been subscribing (on an average the annuity amounts to about thirty-seven dollars) accrues rapidly to those who are incapacitated from labor by accidents not due to their occupations, or by diseases gradually contracted in their occupations. The necessary funds are partly supplied by the State, which adds about twelve dollars annually to the amount subscribed in equal shares by the employer and the workman.

MEDICAL NOTES.

BEQUESTS TO HOSPITALS.—Under the will of the late George M. Pullman, thirteen hospitals and charitable institutions of Chicago will receive \$10,000 each.

PLAGUE IN INDIA.—Plague in India shows no signs of diminishing, and the unpleasant report that Haffkin's antitoxic serum has effected no cures is also in circulation. It is generally conceded, however, that the inoculations are of value for prophylaxis.

YELLOW FEVER IN THE SOUTH.—The following statistics concerning yellow fever have been received in the office of the Supervising Surgeon-General of the United States Marine-Hospital Service during the week ended November 2 referred to

		p of the puerperal state	
		of quinine, Dr. S. MARX, 'hs.	
ALABAMA:		Nov. 13-19, up the question, "V	0 1
Flomaton,	Nov. 13-19,	49	12
Mobile,	Nov. 13-19,	49	12
LOUISIANA:			
New Orleans,	Nov. 14-19,	49	12
MISSISSIPPI:			
Biloxi,	Nov. 14-19,	6	1
Clinton,	Nov. 13-19,	3	0
Edwards,	Nov. 13-19,	5	1
Scranton,	Nov. 13-19,	11	1

On November 22d Mississippi revoked the State quarantine, which was the last to be removed. There were only four new cases and one death reported in New Orleans on that date.

THE AMERICAN SOCIETY OF NATURALISTS.—The American Society of Naturalists and the affiliated societies will meet at Ithaca, N. Y., on December 28th, 29th and 30th. The other societies meeting with the Naturalists are: the Association of American Anatomists, the Association for Botanical Morphology and Physiology, the American Morphological Society, the American Physiological Society, the American Psychological Association, Section II (Anthropology) of the American Association for the Advancement of Science.

KANGAROO PATHOLOGY.—The deprivation of active exercise which is entailed by board and lodging in the Zoölogical Gardens, afflicts the Kangaroo in a marked manner. They develop enormous corns, several ounces in weight, which are very troublesome to remove, and on the approach of damp weather—and damp weather seems to be the rule in the purlieus of Regent's Park—they are prone to gouty manifestations, usually first affecting one hand, or paw, and then the opposite foot.—*Medical Press and Circular.*

DANGEROUS SPORTS.—The foot-ball season is over. The three great college games have been played and were hotly contested, but there were no casualties. Georgia, however, has acquired a law against foot-ball which reminds one of similar legislation in England in the reign of James II. The hunting season is now in full blast and we find a telegram from Houghton, Mich., in the daily press in regard to deer shooting in that State to the following effect: "There is venison on every bush and work for the coroner in almost every township. The Nimrods are mainly armed with new model rifles, carrying small calibre bullets and smokeless powder cartridges. The bullets bound, as a stone cast upon the water, when they strike smooth and hard projections at certain angles. No man in the woods knows where his bullets are going to stop. Up to date nine men have been killed in the upper peninsula. This is the record for nine days. The season lasts until the end of November and the average is expected to keep up to a man a day."

ARCHIVES OF THE RÖNTGEN RAY.—With No. I of Volume II, the American edition of which, though dated July, 1897, has just appeared, the *Archives of Clinical Skiagraphy* changes its name to the *Archives of the Röntgen Ray*. The present number, beside other handsome plates, contains a skiagram of the whole adult body taken at one exposure by Dr. William J. Morton, of New York. The time of exposure was thirty minutes, and the distance of the tube from the plate, four feet six inches. The apparatus employed was a twelve-inch induction coil whose primary was supplied from the 117-volt Edison current of the street mains, and made and broken by a break-wheel which caused about 5,000 breaks per minute. When the break-wheel revolved 5,000 times per minute the current gave a free discharge of sparks across a five-inch air gap; current through primary coil, 3 6-10; voltage at terminals of primary, 75; an ordinary Crookes tube with a consuming vacuum corresponding to a spark of two inches, which gradually rose to eight inches. This is probably the first time that a skiagram of the entire adult human skeleton has been secured at a single exposure.

NEW YORK.

X-RAYS IN A FOOT-BALL INJURY.—In a foot-ball game at Manhattan Field, on November 13th, between the Carlisle Indians and Brown University, Martin Wheelock, of the former team, received a severe but obscure injury of the shoulder, and was taken in an ambulance to the Manhattan Hospital. At the hospital the x-rays were employed to ascertain the nature of the trouble, and it was found that there was a fracture at the shoulder-joint, which had been severely sprained in a match one week before with the University of Pennsylvania team.

THE WORK OF THE LYING-IN HOSPITAL.—The annual report of the Society of the Lying-in Hospital, just published, states that during the past year 3,695

applicants presented themselves at the hospital and sub-station for treatment, and that 2,792 were attended in confinement at their homes in the tenement districts and in the hospital wards. The number of births reported in the city for the year ending October 31, 1897, was 54,692, and out of that number, therefore, more than five per cent. became a charge upon the Society. The cost of conducting the hospital and sub-station for the year, less interest charges and the printing of reports, was \$27,843, making the expense for each patient only about \$9.97. During the year the Medical Board gave instructions to 307 students of midwifery.

PROPOSED MEDICAL EXAMINATION OF JURYMEN.—In view of the unfortunate and expensive results of the illness of the juror in the Thorn trial, who, it was ascertained, had previously suffered from appendicitis, a writer in one of the daily papers has made the suggestion that on the day or days of the selection of a jury in important cases there should be secured the services of a competent physician, whose duty it would be to examine into the physical condition of each talesman accepted for trying the case.

BROKEN NECKS FROM FALLS DOWNSTAIRS.—There are at present in New Jersey two patients living with broken necks, both of whom received fractures of their vertebrae about the same time and in the same way, by falling down a flight of stairs. One of them met with the accident at Bayonne, near Jersey City, and is in the hospital at that place. The other was injured at Bound Brook and was taken to the Newark Hospital. Subsequently he was taken to New York for treatment, but has now been returned to his home at Bound Brook.

MENINGITIS FROM AN UNUSUAL CAUSE.—A child, twenty-one months old, died at Orange, N. J., November 15th, of spinal meningitis, the result of a peculiar accident. On the day previous it fell down with a large darning-needle, which it had found while playing on the floor, in its mouth, and the point of the needle was driven through the back of the throat into the spinal cord.

DEATH AT THE AGE OF ONE HUNDRED AND THREE.—Mrs. Christiana French died in Morristown, N. J., on November 14th, at the well authenticated age of one hundred and three years and three months. She had always enjoyed vigorous health, and about a year ago appeared at court in Trenton to prosecute a suit at law in connection with some property she owned. She leaves a son seventy-three years old, eight grand children and ten great-grandchildren.

THIRTY THOUSAND DOLLARS AWARDED FOR LOSS OF LIFE.—The widow of Dr. Mixsell, a practising physician who was killed by a railway accident at Mamaronech, Westchester County, on the New York, New Haven and Hartford Railroad, has been awarded \$30,000 as compensatory damages, the \$5,000 limit as compensation for death from accidents having been abrogated in New York.

THE WORK OF THE BOARD OF HEALTH.—The Board of Health has made a report to Mayor Strong relating to its work during the three summer months. In those months 2,578,445 pounds of unwholesome meat, milk, fish and fruit were seized and condemned, and 768 analyses were made by the chemists of the Department, of samples of milk, water, whiskey, candy, cigarettes, ice-cream and other articles. The report also states that the death-rate for the summer months was lower than in any year since 1892, being 20.96 per thousand of the estimated population. In 1896 it was 24.25; in 1895, 24.73; in 1894, 22.18; and in 1893, 23.33.

Miscellany.

AN UNUSUAL WEIGHT FOR A CHILD AT TERM.

DR. J. W. HARTIGAN, reports in the *New York Medical Journal* the following unusual case:

"In June," he writes, "I was called to see a young woman in labor, aged twenty-one years; weight, a hundred and twenty pounds; primipara. The child seemed unusually large. I had the father, a very small man, weigh it. He reported eighteen pounds as its weight. I expressed surprise, and got another pair of scales and weighed it myself in the presence of another physician. It weighed on both scales eighteen pounds and four ounces. "The parents were both small and both young. The labor was rather a quick one, and the birth not so hard as I have often seen with much smaller children."

According to Lusk, Seanzoni found an average of nearly seven pounds, for both sexes, in nine thousand births. The average weight of two hundred children born in Bellevue Hospital, according to Dr. Lusk, was seven pounds and two-thirds for both sexes, the heaviest child weighing eleven pounds. Waller reports the forceps extraction of a child weighing fifteen pounds and fifteen ounces.

GENERAL CONCLUSIONS OF THE INTERNATIONAL LEPROSY CONFERENCE, BERLIN, 1897.

At the close of the debates of the International Leprosy Conference, Berlin, 1897, the Secretaries of the Conference presented the following short report of the general conclusions of the Conference, especially for the benefit of those members who have been delegated by their respective governments, and who have to make reports on the results of the Conference.

"As might be expected, a considerable portion of the discussion has related to the bacillus *Leprae*, which the Conference accepts as the *virus* of leprosy, and which for upwards of twenty-five years has been known to the scientific world through the important discovery of Hansen and the able investigations of Neisser.

"The conditions under which the bacillus grows and develops are still unknown, as well as the way of its invasion into the human system; but from the discussions of the Conference, it seems probable that unanimity of opinion will soon prevail in reference to

its modes of subsequent dissemination within the human body.

"Very interesting observations have been brought forward in connection with the elimination of the bacilli in large quantities by means of the skin and the nasal and buccal mucous membranes of lepers; it is desired that such observations be confirmed where opportunities occur.

"The question is of very great importance to those who are entrusted with the care of the public health, as leprosy is now acknowledged to be a contagious disease.

"Every leper is a danger to his surroundings, the danger varying with the nature and extent of his relations therewith, and also with the sanitary conditions under which he lives.

"Although among the lower classes, every leper is especially dangerous to his family and fellow workers, cases of leprosy frequently appear in the higher social circles.

"The theory of heredity of leprosy is now further shown to have lost ground, in comparison with the at present generally accepted theory of its contagiousness.

"The treatment of leprosy has only had palliative results up to the present time.

"Serum therapy has so far been unsuccessful.

"In view of the virtual incurability of leprosy and the serious and detrimental effects which its existence in a community causes, and considering the good results which have followed the adoption of legal measures of isolation in Norway, the Leprosy Conference, as a logical issue of the theory that the disease is contagious, has adopted the following resolution proposed by Dr. Hansen and amended by Dr. Besnier:

"(1) In such countries, where leprosy forms foci or has a great extension, we have in isolation the best means of preventing the spread of the disease.

"(2) The system of obligatory notification, of observation and isolation as carried out in Norway, is recommended to all nations with local self-government and a sufficient number of physicians.

"(3) It should be left to the legal authorities after consultation with the medical authorities to take such measures as are applicable to the special social conditions of the districts."

SUPPLEMENTARY REPORT TO THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK BY ITS COMMITTEE ON THE ABUSES OF MEDICAL CHARITY.¹

THE initial report of your Committee on the Abuses of Medical Charity was transmitted to the Society on the 24th of May last. The report was accepted, and the committee continued, with power to take such steps as appeared to it advisable toward completing the work then under way.

Shortly after that date a joint-committee was formed, composed of representatives from this committee, and from like committees which had been appointed by the County Medical Association, the New York Medical League, and the Society for the Advancement of the Practice of Medicine. Somewhat later this joint-committee was enlarged by accredited representation from the New York State Medical Association and the joint-committee appointed by the Kings County Medical

Society, the Kings County Medical Association, the Brooklyn Medical Society, the Brooklyn Medical Association, and the Long Island Medical Society. As a result of many conferences by this joint-committee, a bill designed to regulate the management of all medical dispensaries in this State has been prepared by the counsel of this Society and referred by the joint-committee to the several societies and associations represented in its membership. The text of this bill reads as follows (we have room only for the first three sections):

SECTION 1. By this act a dispensary is defined to be any corporation, institution, agency or place, society or association, whose purpose it is, either independently or in conjunction with any other purpose, to furnish gratuitously or at a merely nominal price, to indigent, needy or other persons not resident therein, medical or surgical relief, advice or treatment, medicine or orthopedic or other appliances.

SECT. 2. After the passage of this act, it shall not be lawful for any person to conduct a dispensary within this State; unless said person is a corporation, incorporated under the laws of this State and licensed by the State Board of Charities as hereinafter provided.

SECT. 3. Hereafter no dispensary shall be conducted in any place in this State commonly known as a drug store, nor in any place or building in the State defined by law or by an ordinance of a Board of Health as a tenement house; nor shall it be lawful for any dispensary to furnish (except in cases of emergency) medical or surgical relief, advice or treatment, medicine or orthopedic or other appliances to persons other than such as are indigent or needy.

As will be seen, this bill differs essentially from that with which the first report of your committee had to deal, the most important feature being that each and every dispensary must obtain a license from the State Board of Charities, by virtue of which its operations shall be conducted; and that, in case the law, or the rules and regulations framed by the Board, is not complied with, said Board is empowered to revoke the license of the dispensary so offending. The vested rights of corporations will in no wise be interfered with, and the effort to correct the crying abuses now so widely prevalent will not result in injury to those institutions which are, and will be, properly and conscientiously conducted. This bill, as now presented, embodies the result of much painstaking and earnest consideration, and it is hoped that it will receive the hearty and unqualified support of those who have the subject of the correction of medical charity abuse nearest at heart. The State Commissioners of Charity have already been informally consulted regarding its provisions, and after it has been approved by the several societies it is proposed to transmit a copy, containing such modifications as may be deemed advisable, together with other literature which has been prepared, to every legally constituted medical society in the State for indorsement preparatory to its presentation to the Legislature during the first days of the approaching session.

For many obvious reasons, it has been impossible for your committee to complete its labors in season to present a complete report at the present meeting, and although it is customary that a committee such as this one is relieved of its duties when the presiding officer to whom it owes its appointment retires from the Chair, your committee in this instance begs to recommend, with the courteous concurrence of the new President of the Society, that it be continued, with power, until the new Dispensary Bill shall have been presented to the Legislature, at which time the matter with which

¹ Transmitted November 22, 1897.

it has had to do will be turned over to the Committee on Legislation.

It is not the idea of your committee that the universal abuse of dispensary privileges can either be done away with or even adequately controlled all at once, but the enactment of a law, such as provided for in the accompanying bill, will, in its opinion, mark an era in the effort which, during the past twenty years, has been made by so many earnest workers toward this end. Experience has shown that without a law on the statute books, just and equitable alike to the laity and the members of the medical profession, absolutely nothing can be accomplished in the direction of bettering existing conditions, and therefore it is with the full confidence that the Medical Society of the County of New York will heartily indorse the action of its committee, and will attach its seal of approval to this amended Dispensary Bill, as presented by the joint-committee, that this report is submitted.

JAMES HAWLEY BURTENSHAW, M.D., *Chairman.*

Correspondence.

MEDICAL LAWS OF THE STATE OF WASHINGTON.

SEATTLE, WASH., November 10, 1897.

MR. EDITOR:—I am in receipt of many inquiries concerning the medical laws of the State of Washington. I would say that all persons intending to practise medicine or surgery in the State of Washington are obliged to pass an examination before the State Board of Medical Examiners.

These examinations are held the first Tuesday in January and the first Tuesday in July. The January meeting is held on the west side of the Cascade Mountains and the July meeting on the east side.

No temporary certificates are granted by this Board, and no exception is made to this rule.

Very truly yours,

F. H. COE, M.D.,

Secretary Medical Society, State of Washington.

THE BILL FOR A DEPARTMENT OF PUBLIC HEALTH.

WASHINGTON, November 15, 1897.

MR. EDITOR:—Will you kindly permit me to correct a statement made in the editorial columns of your esteemed journal of the issue of November 11, 1897, under the caption, "A Department of Public Health." I refer to the statement in the second paragraph, which reads as follows: "The American Medical Association, at the Philadelphia meeting of this year, adopted a draft for a bill to establish a department of public health." I am informed by the Recording Secretary of the Association and also by others who were present, that the American Medical Association did not adopt a draft for a bill to establish a department of public health.

The facts regarding the proposed bill, referred to in your editorial, are as follows: At the last meeting of the American Medical Association, the Committee of the Association on Department of Public Health, through its chairman, Dr. U. O. B. Wingate, of Wisconsin, read a report of the Committee, in which was included the draft of a bill providing for a department of public health. The report of the Committee was received by the Association, and the Committee continued. As the proposed bill was presented during the last hours of the meeting of the Association,

when few were present, it was *not discussed, adopted or rejected* by the Association. An opinion on the merits or demerits of the proposed bill was not expressed by the Association. In fact, the American Medical Association, the year previous, at the Atlanta meeting, in adopting a report of its Committee on Department of Public Health, which report recommended that the Committee be authorized to draft a bill which should be in accord with the recommendations of their report, expressed views which are entirely opposite to those embraced in the report of the Committee at the last meeting, recommending the proposed bill for a Department of Public Health. It is proper to state that by reason of the death of Dr. Jerome Cochran, the Chairman of the Committee in 1896, a new Chairman was appointed.

You are, undoubtedly, misled in the statement in your editorial by the editorial statement in the *Journal of the Association*, as was the case with some members present at the last meeting of the American Public Health Association. The statement that the proposed bill was adopted by the American Medical Association was announced at that meeting, which, undoubtedly, influenced members in voting for it. However, there were only nineteen votes for the bill, and seven against it at the meeting of the Public Health Association, whose average membership is about eight hundred.

Very truly yours,

H. W. AUSTIN, M.D.

[We find that the statements in regard to the American Medical Association contained in the above communication are substantially correct, and publish them with pleasure. Practically it seems to be a question whether the proposed Department of Public Health should swallow or be swallowed by the Marine-Hospital Service. — Ed.]

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, NOVEMBER 13, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Amesbury . .	10,920	—	—	—	—	—	—	—

Deaths reported 2,189; under five years of age 634; principal infectious diseases (small-pox, measles, diphtheria and croup,

cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas, and fevers) 257, acute lung diseases 286, consumption 258, diphtheria and croup 89, diarrheal diseases 62, typhoid fever 44, scarlet fever 16, whooping-cough 11, measles 10, cerebro-spinal meningitis 10, malarial fever 9, erysipelas 6.

From scarlet fever New York 11, Chicago, St. Louis, Pittsburg, Fall River and Newton 1 each. From whooping-cough New York and Pittsburg 3 each, Chicago 2, Baltimore, Washington and Charleston 1 each. From measles New York 10. From cerebro-spinal meningitis New York 3, Boston 2, Baltimore, Providence, Worcester, Chelsea and Newton 1 each. From malarial fever St. Louis 4, Nashville 3, Chelsea and Fitchburg 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending November 6th, the death-rate was 18.1. Deaths reported 3,823, acute diseases of the respiratory organs (London) 363, measles 128, diphtheria 82, diarrheal 64, fever 51, scarlet fever 46, whooping-cough 41.

The death-rates ranged from 11.2 in Croydon to 23.4 in Liverpool; Birmingham 20.7, Bradford 14.9, Cardiff 15.3, Gateshead 15.0, Huddersfield 20.0, Leeds 19.2, Leicester 11.5, London 18.5, Newcastle-on-Tyne 19.4, Nottingham 15.9, Salford 16.9, Sunderland 15.0, West Ham 16.8.

METEOROLOGICAL RECORD

For the week ending November 13th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 13, 1897, TO NOVEMBER 19, 1897.

By direction of the President, the retirement from active service this date, November 15, 1897, of **LIEUT.-COL. WILLIAM E. WATERS**, deputy surgeon-general, is announced.

CAPTAIN RICHARD W. JOHNSON, assistant surgeon, is relieved from duty at Fort Logan, Col., and ordered to Fort D. A. Russell, Wyo., for duty.

CAPTAIN CHARLES E. WOODRUFF, assistant surgeon, will upon the abandonment of Fort Custer, Mon., proceed to Jackson Barracks, La., and report for duty at that post, to relieve **MAJOR WILLIAM C. SHANNON**, surgeon.

Leave of absence for one month is granted **CAPTAIN R. G. EBERT**, assistant surgeon.

LIEUT.-COL. J. V. D. MIDDLETON, deputy surgeon-general, granted one month's extension to present leave of absence.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 20, 1897.

C. G. HERNDON, surgeon, detached from the Bureau of Medicine and Surgery and placed on waiting orders.

J. C. THOMPSON, assistant surgeon, detached from the Naval Laboratory, Brooklyn, and ordered to the Naval Hospital, Mare Island, Cal.

W. B. GROVE, assistant surgeon, detached from the Naval Hospital, Mare Island, Cal., on reporting of relief, and ordered to the "Oregon."

T. B. BAILEY, passed assistant surgeon, detached from "Yorktown," and ordered home with two months' leave.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING NOVEMBER 18, 1897.

SAWTELLE, H. W., surgeon. To rejoin station at New Orleans, La., via Washington, D. C. November 17, 1897.

WHITE, J. H., passed assistant surgeon. To rejoin station at New York, N. Y., upon completion of duties at New Orleans, La. November 16, 1897.

PETTUS, W. J., passed assistant surgeon. Granted leave of absence for one month from December 14, 1897, with permission to go beyond sea. November 13, 1897.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, November 29th, at 8 o'clock.

Dr. C. F. Withington will read a paper entitled: "Pulmonary Abscess and Gangrene."

Dr. C. L. Scudder: "Tuberculosis of the Breast."

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION.—The Surgical Section will meet at the Medical Library, 19 Boylston Place, on Wednesday evening, December 1st, at 8 o'clock.

Papers: "Indications for Nephrectomy," by **Dr. M. H. Richardson**.

"The Value and Limitations of the Ureteral Catheters and Bougies in Cases of Pyonephrosis," by **Dr. Edward Reynolds**.

"Cystitis in Young Girls, with a Report of Three Nephrectomies," by **Dr. Edgar Gareean**.

The presentation of pathological specimens of surgical interest is invited.

PAUL THORNDIKE, M.D., Secretary, 244 Marlborough St.

AMERICAN ASSOCIATION FOR THE STUDY AND CURE OF INEBRIETY. The twenty-seventh annual meeting of this Association will be held December 8, 1897, in the Hall of the Washington Home, 41 Waltham Street, Boston, Mass.

The morning session will begin at 10.30.

The annual address will be delivered at the evening session at 8 o'clock, by **Dr. Ira Van Gieson**, Director of the New York State Pathological Institute: "On Some Recent Researches on the Action of Alcohol on Brain Cells."

The profession is cordially invited to attend.

T. D. CROTHERS, M.D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.

Essentials of Bacteriology; being a Concise and Systematic Introduction to the study of Micro-organisms for the Use of Students and Practitioners. By **M. V. Ball, M.D.**, Bacteriologist to St. Agnes' Hospital, Philadelphia. Third edition, revised. With 81 illustrations, some in colors and five plates. Philadelphia: W. B. Saunders. 1897.

A Text-Book of the Practice of Medicine. By **James M. Anders, M.D., Ph.D., LL.D.**, Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College, Philadelphia; Attending Physician to the Medico-Chirurgical and Samaritan Hospitals, Philadelphia, etc. Illustrated. Philadelphia: W. B. Saunders. 1897.

The Principles of Bacteriology; A Practical Manual for Students and Physicians. By **A. C. Abbott, M.D.**, Professor of Hygiene and Director of the Laboratory of Hygiene, University of Pennsylvania. Fourth edition, enlarged and thoroughly revised. With 106 illustrations, of which 19 are colored. Philadelphia and New York: Lea Brothers & Co. 1897.

Outlines of Anatomy; A Guide to the Methodical Study of the Human Body in the Dissecting Room. By **Edmund W. Holmes, A.B., M.D.**, Demonstrator of Anatomy, University of Pennsylvania; Surgeon to the Methodist Episcopal Hospital; Consulting Surgeon to the State Asylum for the Insane, Norristown; Consulting Surgeon to the Northern Dispensary, etc. Published by the Author. 1897.

Surgical Pathology and Principles. By **J. Jackson Clarke, M.B. (Lond.)**, F.R.C.S., Assistant Surgeon at the Northwest London and City Orthopedic Hospitals; Late Senior Demonstrator of Anatomy, Demonstrator of Bacteriology and Curator of the Museum in St. Mary's Hospital Medical School, and Pathologist to St. Mary's Hospital. THE BACTERIOLOGY OF LOBAR AND LOBULAR PNEUMONIA: VARIOUS INFECTIONS DUE TO THE DIPLOCOCCUS LANCEOLATUS.¹

BY RICHARD MILLS PEARCE, M.D.,

First Resident Assistant Pathologist, Boston City Hospital.

This paper is a report of all the cases of acute lobar pneumonia and acute broncho-pneumonia which have come to autopsy and have been studied bacteriologically at the Boston City Hospital between May 1, 1894, and May 1, 1897. It includes also the report of various infections, due to the pneumococcus, found at autopsy or at operation. The work has been carried on under the direction of Prof. W. T. Councilman, in the Pathological Laboratory of the Boston City Hospital. The methods of study pursued were those usually employed. Löffler's blood serum, in the form of "slants," prepared according to Mallory's¹ modification, was the culture medium used. Cultures were taken from the solidified lung, pleural and pericardial exudates, if present, and from heart's blood, liver, spleen, kidney and various lymphatic glands. In most cases direct examination by cover-slip preparations was also made.

In taking cultures from the solidified lung a considerable amount of the exudate was used; and generally more than one tube was inoculated. Blood serum was used, because upon it the ordinary pathogenic bacteria grow much more quickly and equally as characteristically as upon agar-agar. This is especially true of the pneumococcus, which after twenty-four hours shows an excellent growth in the form of minute colonies, somewhat smaller than those of the streptococcus, glistening and slightly granular, and usually more moist. It is probably due to the use of this excellent culture medium and the ease with which the pneumococcus grows upon it that in this series of examinations it has been more frequently found than in the cases reported by other investigators.

The recognition and identification of the pneumococcus have been based upon the appearance of the colonies as described above, and upon the microscopical examination of the colonies, which are made up of small oval organisms arranged in pairs, having lancet-shaped or conical ends. Slight variations in form and size have been noted, and short chains have been observed occasionally in the water of condensation; but these are readily distinguished from the streptococcus with its hemispherical elements.

I. ACUTE LOBAR PNEUMONIA.

Since the discovery of the organism now known as the pneumococcus or diplococcus lanceolatus, much work has been done by various observers with a view to demonstrating its etiological relation to pneumonia.

Frankel² states that it is the usual and most frequent organism associated with that disease. Out of 129 cases of lobar and lobular pneumonia, Weichselbaum³ obtained it in 94 cases (78 of which were lobar pneumonia), the streptococcus in 21 cases, and the bacillus of Friedländer in nine cases. In 70 cases Wolff⁴ found the pneumococcus 66 times, and the bacillus of Friedländer three times. Netter⁵ states that it occurred in 75 per cent. of his cases. Gameléia⁶ found it in 12 cases; and considers Friedländer's bacillus as a simple saprophyte "which is only occasionally accidentally

present." Welch,⁷ in a report of 50 cases, considers the pneumococcus as the usual causative agent of acute lobar pneumonia in man. Wright and Stokes⁸ found it in 38 out of 42 cases, and the bacillus of Friedländer not at all.

In this report of 121 cases the pneumococcus was found in the solidified lung in 110 cases, in 84 of which the pneumococcus was the only micro-organism present. In the remaining 26 cases the organisms associated with it were: staphylococcus pyogenes aureus, nine times; streptococcus pyogenes, eight times; staphylococcus pyogenes aureus and streptococcus pyogenes, three times; streptococcus pyogenes and staphylococcus pyogenes albus, twice; bacillus capsulatus (Wright), once; staphylococcus pyogenes albus, once; Klebs-Löffler bacillus, once; Klebs-Löffler bacillus and streptococcus, once.

(In this summary the presence of the bacillus coli communis has not been considered of sufficient importance for classification.)

In the remaining 11 cases, no lung cultures were taken in four, probably through neglect; but in one of these four the pneumococcus was present in pleural and pericardial exudates, in a second in heart's blood, liver and spleen and kidney, in a third in heart's blood and spleen, and in a fourth in spleen and kidney. In two of the remaining seven cases the lung cultures were lost; but in one of them the pneumococcus was present in pericardial exudate and kidney, and in the other in liver and spleen. In two other cases the lung cultures were sterile, but in one the pneumococcus was present in the heart's blood, liver, spleen and kidney, and in the other in pleural exudate and kidney. As the source of the general pneumococcus infection in these cases was evidently the solidified lung, and as the associated inflammation of pericardium and pleura showed the pneumococcus to be present, it seems justifiable to conclude that the pneumonia was due to the same micro-organism and that if cultures had been examined in the first six cases it would have been found; and that its absence in the last two cases was probably due to some error in technique. If these eight cases are therefore added to the others, they make a total of 118 cases out of 121, or 97.5 per cent., in which the pneumococcus was present in the lung.

With the exception of the eight cases just considered, in only three cases of the 121 was the pneumococcus not present in the solidified lung or pleural exudate. These cases, both macroscopically and microscopically, were true lobar pneumonia. In one case there was a general staphylococcus infection following epididymitis, cystitis and pyelo-nephritis. Cultures from lung showed abundant growth of staphylococcus pyogenes aureus. In the second case, complicating typhoid fever, lung cultures showed abundant growth of a streptococcus. It is very probable that in both these cases the pneumococcus was inhibited in its growth, or was present in small numbers, but obscured by the profuse growth of the other organism. The third case was an old pneumonia, well along in the third stage, in which the staphylococcus pyogenes albus only was found. It is very probable that in this the pneumococcus was the causative agent, but had died out. The bacillus of Friedländer was not met with at all.

COMPLICATIONS.

In the exudate of acute pleuritis and acute pericarditis associated with pneumonia, the pneumococcus was

¹ Read before the Boston Society of Medical Sciences, June 1, 1897.

found in every case in which examinations were made — 49 times in pleural exudates, and 15 times in pericardial exudates. These results agree with those of Netter,⁹ Levy¹⁰ and Jakowski,¹¹ who state that the pneumococcus is the usual cause of meta-pneumonic pleurisy; and with Wright and Stokes,⁸ who found it in 12 of 13 cases of pericardial exudate.

Abscess of lung following pneumonia occurred in three cases; in two of these the pneumococcus was the only organism present. In the third case, which was an unresolved pneumonia, the staphylococcus pyogenes aureus and the streptococcus pyogenes were present in addition to the pneumococcus.

In two cases in which an acute meningitis, and in three cases in which an acute endocarditis was associated with or followed the pneumonia, the pneumococcus was present in pure culture. This was also true of one case of acute fibrinous peritonitis.

GENERAL INFECTION.

In looking over the literature the question of general infection with the pneumococcus in the course of pneumonia does not appear to have received much attention. It was found in the circulating blood during life, by Belfanti¹² in six cases, and by Boulay¹³ in two cases. At autopsy it has been found in the blood by Pernice and Alessi¹⁴ in two cases and by Netter⁶ and Levy¹⁰ each in one case; in the kidneys, by Fanlhaber in 29 cases, and by Fränkel and Reiche in 22 cases out of 26 cases; in the spleen by Proir¹⁵ in five cases, and also by Sée¹⁶ and Bordas.¹⁷ In ten cases, Welch⁷ found it in the spleen four times, kidney and heart's blood each once. Wright and Stokes,⁸ in 26 cases, found it in the liver eight times, and in the heart's blood in three out of eleven cases.

In this series of 118 cases, the pneumococcus was found in the heart's blood 56 times, liver 44 times, spleen 47 times, kidney 51 times; and in two cases in which the exudation extended from the pleura upwards into the neck following the posterior mediastinum the pneumococcus was found in the exudation in these tissues and in the cervical glands.

As regards the intensity of the infection, in 18 cases it was found in all the organs, that is, heart's blood, liver, spleen and kidney; in 18 cases in three, in 21 cases in two, and in 24 cases in at least one of the above organs.

CONCLUSIONS.

The pneumococcus is almost universally present in true lobar pneumonia and its complications. Its presence in pure culture in the majority of cases indicates its etiological relation. General infection, in fatal cases, is quite frequent, and therefore of considerable importance, both from a bacteriological and from a clinical point of view.

II. ACUTE BRONCHO-PNEUMONIA.

This report includes 128 cases, which may be divided into two classes: first, those associated with the acute infectious diseases of childhood, 82 cases; and, second, those associated with other medical and surgical affections and generally occurring in adults, 46 cases.

Of this first class 62 were associated with diphtheria alone, and the organism present was Klebs-Löffler bacillus 52 times, streptococcus pyogenes 27 times, staphylococcus pyogenes aureus 11 times, staphylococcus pyogenes albus once and the pneumococcus once.

The Klebs-Löffler bacillus occurred alone in 17 cases; streptococcus pyogenes alone in seven cases; Klebs-Löffler bacillus and streptococcus pyogenes in 16 cases; Klebs-Löffler bacillus and staphylococcus pyogenes aureus in seven cases, and Klebs-Löffler bacillus, staphylococcus pyogenes aureus and streptococcus pyogenes in eight cases, Klebs-Löffler bacillus, staphylococcus pyogenes aureus and streptococcus pyogenes in two cases, Klebs-Löffler bacillus and pneumococcus in one case, Klebs-Löffler bacillus and staphylococcus pyogenes albus in one case, Klebs-Löffler bacillus streptococcus pyogenes and pneumococcus in one case, Klebs-Löffler bacillus, staphylococcus pyogenes aureus and pneumococcus in one case, streptococcus and pneumococcus in one case.

In nine cases of scarlet fever and diphtheria combined, the Klebs-Löffler bacillus was present in every case; in five cases alone, and in the other four cases associated with the streptococcus pyogenes, the streptococcus pyogenes and the staphylococcus pyogenes aureus, the streptococcus pyogenes and the pneumococcus and the staphylococcus pyogenes aureus and the pneumococcus, respectively.

In two cases of diphtheria and measles combined, the Klebs-Löffler bacillus, the streptococcus pyogenes, and the staphylococcus pyogenes aureus were present in each case.

In nine cases of scarlet fever the streptococcus pyogenes was found in two cases, pneumococcus in two cases, staphylococcus pyogenes aureus in one case, streptococcus pyogenes and staphylococcus pyogenes aureus in three cases, pneumococcus and staphylococcus pyogenes aureus in one case.

The association of the Klebs-Löffler bacillus with broncho-pneumonia in such a large proportion of the cases, 63 out of 73, would indicate that its presence was more than accidental, and its occurrence in pure culture in 17 cases strengthens the theory that broncho-pneumonia may be due to the action of this organism, with or without the aid of the pyogenic cocci. This view is held by Wright and Stokes,⁸ who found it present in 18 out of 19 cases, in eight of which it was obtained in pure culture, and by Kanthack and Stephens,¹⁸ who found it in most of their cases.

Its presence has also been observed by Thaon,¹⁹ by Johnson²⁰ in one case, by Strelitz²¹ in one out of eight, by Flexner²² in one out of two, by Mosny²³ in one out of three, by Kutchner²⁴ in eight out of nine cases, by Frosch,²⁵ and by Netter²⁶ in four out of seven cases.

Of other organisms associated with the broncho-pneumonia of diphtheria and scarlet fever, the streptococcus pyogenes is the most common, as shown by the work of Fränkel,² Prudden,²⁷ Neumann,²⁸ Mosny,²³ Northrup,²⁷ Wright and Stokes.⁸

In this series of 82 cases it occurred 44 times. The pneumococcus was present in only eight cases; and it is of interest that five of these were scarlet fever cases. In two of the latter it was obtained in pure culture. Netter²⁶ reports four cases of broncho-pneumonia associated with scarlet fever, in two of which the pneumococcus and streptococcus pyogenes occurred; and Queissner²⁹ reports four cases, in each of which the pneumococcus was found alone or associated with some one of the pyogenic cocci. Netter reports 42 cases of broncho-pneumonia in children, which, with the exception of the 11 cases quoted above, were not associated with either diphtheria or scarlet fever.

He found the pneumococcus in 10 cases, the streptococcus pyogenes in eight, and the staphylococcus pyogenes aureus in five, the bacillus of Friedländer in two cases and in the other 17 cases various combinations of these organisms.

Wollstein⁴⁵ reports 33 cases studied at the Babes' Hospital, New York. Of these 19 were primary, in 17 of which the pneumococcus was found, occurring alone in nine, with the streptococcus in seven, and with staphylococci in one. Of the two remaining cases, the streptococcus was found in one and staphylococci in the other. In 14 cases secondary to measles, diphtheria, marasmus and scarlet fever, the pneumococcus was found in 11 cases, in two of which (measles) it was obtained in pure culture. In the other cases it was associated with the streptococcus and staphylococci.

The second class of broncho-pneumonias, 46 in number, occurring principally in adults, are best studied by grouping them according to the diseases with which they were associated, as follows:

Typhoid fever, five cases: the colon bacillus in two, the pneumococcus alone in one; and the pneumococcus, streptococcus pyogenes and staphylococcus pyogenes aureus in one. In the fifth, which was also complicated by diphtheria, the Klebs-Löffler bacillus, staphylococcus pyogenes aureus and the bacillus capsulatus (Wright) were found.

Chronic purulent bronchitis, four cases: in two the streptococcus pyogenes alone, the pneumococcus in one, the staphylococcus pyogenes aureus in one.

Gangrene of lung, one case: colon bacillus only.

Chronic pulmonary tuberculosis (with associated non-tubercular broncho-pneumonia), three cases: in one the pneumococcus, in another the staphylococcus pyogenes aureus and in the third both the streptococcus pyogenes and staphylococcus pyogenes aureus.

Acute milary tuberculosis, one case: streptococcus pyogenes, general infection.

Pulmonary thrombosis, two cases: pneumococcus in one, colon bacillus in the other.

Acute meningitis, four cases: in each the same organism was found in the broncho-pneumonia as in the meningeal exudate, in three the streptococcus pyogenes, in one the pneumococcus. In each of these cases there was a general infection.

Erysipelas, two cases: in one the staphylococcus pyogenes aureus alone, in the other the streptococcus pyogenes and the staphylococcus pyogenes aureus.

Gangrene, two cases: of neck and foot respectively; the staphylococcus pyogenes aureus alone in one case and associated with the pneumococcus in the other.

Acute nephritis, one case: the streptococcus pyogenes and the pneumococcus, general infection.

Chronic cardiac and renal diseases, six cases: in three the pneumococcus alone with general infection, the streptococcus pyogenes alone in two cases and the staphylococcus pyogenes aureus in one case.

Chronic nephritis, two cases: in one the pneumococcus and staphylococcus pyogenes aureus and in the other the pneumococcus and streptococcus pyogenes.

Acute ulcerative endocarditis, two cases: the streptococcus pyogenes in one, the pneumococcus in the other.

Intestinal affections, four cases: in three of these (diphtheritic colitis, chronic colitis and appendicitis, respectively) the process in the lung was due to the streptococcus pyogenes; in the fourth (acute intussusception), the streptococcus pyogenes and the pneumococcus.

Acute peritonitis, one case: colon bacillus the only organism present.

Cerebral hemorrhage or thrombosis, three cases, the pneumococcus alone in two, the staphylococcus pyogenes albus in the third.

Multiple injuries with cerebral hemorrhages, one case, the streptococcus pyogenes.

Acute suppurative inflammation of the middle ear, two cases, the streptococcus pyogenes alone in one, the streptococcus, pneumococcus and staphylococcus pyogenes aureus in the other.

Puerperal septicemia, one case, the streptococcus pyogenes.

To sum up, the streptococcus pyogenes occurred alone in 16 cases; pneumococcus alone in 12 cases; staphylococcus pyogenes aureus alone in six cases; staphylococcus pyogenes albus alone in one case; colon bacillus, in five cases; streptococcus pyogenes,

staphylococcus pyogenes aureus and pneumococcus, in two cases; streptococcus pyogenes and staphylococcus pyogenes aureus, one case; streptococcus pyogenes and pneumococcus, two cases; pneumococcus and staphylococcus pyogenes aureus, one case.

(Of the five cases in which the colon bacillus occurred alone there was a general infection, in two with the colon bacillus, in one with the streptococcus pyogenes, in one with the typhoid bacillus, and in the fifth all other organs were sterile.)

It is noticeable in all cases where a local or a general infection existed, the associated broncho-pneumonia was due to the same micro-organism; but where the condition was a chronic or non-infectious process, as a chronic cardiac and renal disease, cerebral hemorrhage, etc., the broncho-pneumonia was generally due to the pneumococcus; thus, of the 12 cases in which the pneumococcus occurred alone, eight were chronic diseases.

In reviewing the literature few reports on broncho-pneumonia in adults were found. Netter,²⁶ in 53 cases, found the pneumococcus 15 times, the streptococcus 12 times, the bacillus of Friedländer nine times, staphylococci three times, and various combinations of these organisms in 11 other cases.

Weichselbaum,⁸ in a report of 25 cases, found the pneumococcus 12 times, the streptococcus pyogenes seven times, staphylococci three times, bacillus capsulatus twice, and both the pneumococcus and the staphylococcus pyogenes aureus once. Banti,⁸⁰ in four cases, found the pneumococcus alone in one case, associated with staphylococci in one case, the bacillus capsulatus alone once, and streptococcus pyogenes with staphylococci once.

III. VARIOUS INFECTIONS DUE TO THE PNEUMOCOCCUS. 56 CASES.

The autopsy records show 26 acute infections processes in which the pneumococcus was present, and which were not accompanied or preceded by lobar pneumonia. These are divided as follows: acute ulcerative endocarditis, six cases; two were associated with chronic pulmonary tuberculosis; one with a broncho-pneumonia; one with an abscess of the myocardium; and in two there were no lesions besides the endocarditis. The pneumococcus was the only organism present, and was demonstrated in five cases by culture and in one by stained section of valve. In three cases there was a general infection.

Acute purulent meningitis, five cases; two of these followed suppurative disease of the middle ear due to infection through the Eustachian tube after fracture of base of skull through petrous portion of temporal bone. (These two cases have already been reported by Wright and Stokes.⁸) Pure culture of the pneumococcus was obtained in each case, and a general infection was present in each case. The third was associated with a broncho-pneumonia. Pneumococcus was obtained in pure culture. The two other cases were apparently primary infections. The pneumococcus occurred alone in one, and in the other was associated with the streptococcus and the diplococcus intra-cellularis meningitidis.

Acute fibrinous pericarditis, three cases. The pneumococcus was obtained in pure culture in each case. One case was accompanied by acute fibrinous pleuritis with general infection (reported by Wright and Stokes⁸).

Acute fibrinous peritonitis six cases, one followed operation for radical cure of inguinal hernia; the pneumococcus was present in pure culture; general infection. Two cases followed an acute endometritis, the pneumococcus present in pure culture, and also demonstrated in the endometrium and Fallopian tubes; general infection in both cases. One case followed rupture of a pyosalpinx: pneumococcus was present in pure culture. One case followed perforation of the rectum with formation of pelvic abscess: colon bacillus and staphylococcus pyogenes citreus present in addition to the pneumococcus. In the sixth case following appendicitis there was a profuse growth of the pneumococcus with five colonies of staphylococcus pyogenes aureus.

Weichselbaum³¹ and Barbacci³² each report two cases; and Fränkel³³ and LeGendre³⁴ each one case of peritonitis due to the pneumococcus. The latter, LeGendre, states that the literature shows 11 cases, eight of which terminated fatally.

In the following six cases there was a general (terminal) infection with the pneumococcus. In three cases associated with leukemia, chronic pulmonary tuberculosis and general sarcomatosis (with broncho-pneumonia) respectively, it was present in pure culture, except in kidney of last case, which had also the staphylococcus aureus. (This last case has been previously reported by Dr. Wright.⁸) In a fourth case, liver abscess following appendicitis, the pneumococcus and staphylococcus pyogenes aureus were present; in the fifth case, diabetes with carbuncle, the pneumococcus and the staphylococcus pyogenes aureus were present; the sixth case, an acute septicemia with peculiar rash, congestion of the lungs, and acute degenerative changes in all the organs showed pneumococcus in the lung, spleen and kidney. In all these cases the infection-atrism is evident, except in the first and last.

The surgical and medical records show that in 29 cases the pneumococcus was the infectious agent. These infections are divided as follows: pleuritis, 15 cases, in seven of which the exudate was sero-fibrinous and the pneumococcus was present in pure culture. In eight cases of purulent pleuritis the pneumococcus was present in pure culture in six, and associated with the streptococcus pyogenes in two. These cases were, of course, all coincident with acute lobar pneumonia.

Fränkel³⁵ reports the pneumococcus in three cases of empyema, Hoplik³⁶ in seven, Prudden in nine, and Netter⁹ in 14 out of 46. Wright and Stokes⁸ found it in 12 out of 13 cases of fibrinous pleurisy and in four cases of empyema, in two of which the staphylococcus pyogenes aureus was also present.

Acute abscess, seven cases. In four of these the pneumococcus was present in pure culture. They were respectively, deep cervical abscess, abscess of leg, of upper eyelid, and of liver communicating with pleural cavity. The fifth was of the face, and had the staphylococcus pyogenes aureus in addition to the pneumococcus. The sixth, abscess involving seminal vesicles, by cover-slip examination showed abundant lanceolate diplococci, with distinct capsules (stained by Welch's⁷ method). Cultures showed, in addition to pneumococci, a few streptococci and colon bacilli, evidently a contamination. The seventh was of the finger, and the streptococcus pyogenes and the pneumococcus were present.

Acute abscesses due to pneumococcus are rare. Testi³⁷ reports two of the parotid gland, one of which was as-

sociated with a pleuritis; Gabbi,³⁸ one case of tonsillar abscess; Monti³⁹ and Belfanti, a purulent arthritis; and Ortmann and Samter⁴⁰ a purulent inflammation of the shoulder-joint. The last two followed pneumonia.

Acute suppurative otitis media, two cases; pneumococcus alone in one; and in the other associated with the staphylococcus pyogenes aureus.

Acute suppurative mastoiditis, three cases; the pneumococcus alone in one, and associated with the streptococcus pyogenes in the other.

Of middle-ear diseases, Yauful⁴¹ reports six; Levy and Shrader⁴² three out of 10; and Netter,⁴³ five out of 18 cases due to pneumococcus.

Acute purulent peritonitis, one case, pneumococcus and colon bacillus present.

Gangrenous appendicitis, one case, pneumococcus and colon bacillus present.

Pyosalpinx one case, pneumococcus present in pure culture. The presence of the pneumococcus in this affection is extremely uncommon. I have found only one definite case in the literature I have examined, that of Zweifel,⁴⁴ who in 71 cases found it but once.

The presence of the pneumococcus in these acute infections indicates that in addition to the production of its specific process in the lung, it may also, as is occasionally observed with the tubercle bacillus, the typhoid bacillus and the Klebs-Löffler bacillus, produce acute suppuration.

LOVE'S YOUNG DREAM. — A man aged one hundred years and one month was married in St. Joseph, Mo., on November 18th, to a widow aged seventy-seven years.

THE CHEMICAL ANALYSIS OF THE GASTRIC CONTENTS.

I. METHOD OF ANALYSIS FOR USE IN CLINICAL WORK.
II. RECORD OF THE ANALYSES OF THE GASTRIC CONTENTS OF FIFTY HEALTHY INDIVIDUALS.BY HENRY F. HEWES, M.D.,
Assistant in Chemistry, Harvard Medical School, Boston.

(Concluded from No. 22, p. 542.)

LACTIC acid is not a constituent of gastric juice, and is not produced in the stomach during the course of normal gastric digestion.^{59 60} Statements contrary to this are found in many of the leading text-books; but the truth of the above statement has been adequately demonstrated by the researches of Bidder and Schmidt, Rothschild, Martius and Lutke, Boas and others.⁵⁹

The presence of this acid, therefore, in the gastric contents, except in the amount ingested in the food as acid or salts, is of pathological significance.⁶⁰

The best test for lactic acid for practical work is the ferric-chloride test. A colorless solution of neutral ferric chloride is turned a lemon-yellow (gelbgrün) color by lactic acid. A more striking application of this test is seen in the Uffleman lactic acid test.⁶² Uffleman's solution consists of 10 c. c. of four per cent. carbolic acid, 20 c. c. of water and one drop of 10 per cent. neutral ferric chloride. The pale amethyst color of this solution is bleached and replaced by a lemon-yellow color by the addition of lactic acid.

This ferric-chloride test responds to the presence of half a gramme per mille lactic acid. As the amount of lactic acid contained in the Ewald test breakfast is at most one-tenth of a gramme per mille, this test can be used as an index of the presence of produced lactic acid after the ingestion of this meal.^{61 63}

In testing for lactic acid in the gastric contents this ferric-chloride test must be used in a modified form, since the straight test or Uffleman modification are interfered with by certain substances which may be present in the normal or pathological contents.^{61 64}

Thus glucose, alcohol, peptones, carbonates, bile, butyric acid, potassic sulpho-cyanide, all substances which may be present in the gastric contents, may to a greater or less degree simulate the test.⁶¹ Phosphates, hydrochloric acid and fatty acids, if in sufficient amount,⁶¹ inhibit the test. These substances must therefore be excluded before making the test for lactic acid in the contents. A most satisfactory method of excluding these substances and testing for lactic acid in the gastric contents is the De Jong method.⁶⁶

To five cubic centimetres of the gastric contents add two drops of strong hydrochloric acid; heat the mixture to a syrupy consistency over a flame or water-bath; shake the residue with ten cubic centimetres of ether; separate the ether; to this ethereal extract add five cubic centimetres of water and one drop of five per cent. neutral ferric chloride. If lactic acid be

present in amount over a half-gramme per mille, a lemon-yellow color will be obtained.⁶⁶

In this process butyric acid, potassic sulpho-cyanide, fatty acids and alcohol, if present, are separated by the addition of free hydrochloric acid and subsequent evaporation. These substances would otherwise be taken up by the ether. The lactic acid is taken up by the ether, while the remaining substances, as glucose, peptones, etc., remain in the residual contents.⁶⁷ This test includes both free lactic acid and lactates. It will not react to the amount of lactic acid contained in an Ewald test breakfast.⁶⁸

If it is desired to detect the production of very small quantities of lactic acid (2 gm. per mille) the method of Boas must be used. For this test a meal containing no lactic acid is ingested. Boas' meal consists of an oatmeal soup, prepared by boiling one drachm of oatmeal in one litre of water. One or more hours after ingestion the contents are expressed, and subjected to a very delicate test for lactic acid devised by Boas.⁶⁷

According to our present ideas, the production of lactic acid during gastric digestion occurs as the result of the fermentation of the carbohydrate foods, through the agency of certain bacterial organisms. Whether this fermentation is due to one definite organism or to several different forms of bacteria is not definitely settled. Huffer first demonstrated by scientific methods a specific bacillus as a cause of lactic acid fermentation. This bacillus (*acidilactici*) is a short, plump, rod-shaped organism 1 to 1.7 μ in length by 0.3 to .4 μ in thickness.⁶⁹

Miller has found several kinds of lactic-acid-forming bacteria in the mouth in normal conditions—among others, one similar to this bacillus of Huffer in morphological and physiological characteristics.⁷⁰ Kauffman and Schlesinger, Rosenheim and others have found that the presence of large numbers of a large bacillus of a type found in the mouth is characteristic of the gastric contents where lactic acid is produced.^{71 72} The action of this bacillus is inhibited by an acidity of seven-tenths per mille free hydrochloric acid or one to two per mille combined hydrochloric acid. In the normal stomach the action of the bacillus is inhibited by the increasing acidity, before any appreciable fermentation can be produced by the few bacilli swallowed with the food.

Where, in pathological conditions, the secretion of hydrochloric acid is absent or slight, and the presence of stenosis or dilatation with resulting stasis of the contents gives a long period for action to the bacillus, great multiplication of the bacilli and fermentation of large amounts of lactic acid occur.⁷³ This condition is most associated with carcinoma of the stomach, where the combination of the conditions of atrophy of the secreting structures and of stenosis is most common. It may occur in other conditions.⁷³

Butyric acid is not a constituent of the gastric juice.

⁵⁹ Martius u. Lutke, Magensaure d. Menschen, have proved this conclusively by establishing a comparison of the total acidity and the total hydrochloric acid and finding that they coincide or run parallel throughout digestion.

It is formed from carbohydrate and milk foods by the action of several bacilli, among them the bacillus butyricus. Physiologically it may occur in the gastric contents after the ingestion of large amounts of carbohydrate foods or milk. After an Ewald meal the amount of butyric acid is never enough in the normal stomach to appear in the tests one hour after ingestion. In pathological conditions, however, lactic butyric may be present in the contents.

The tests of butyric acid are as follows: Ten cubic centimetres of the contents are shaken with 50 c. c. of ether, the ether drawn off and evaporated, and the residue dissolved in water. To this aqueous solution lumps of calcium chloride are added. If butyric acid is present in amount sufficient to be of pathological significance, globules of the acid will separate out in the solution. Butyric acid may be discovered also by adding to the contents alcohol and sulphuric acid, and heating. If butyric acid be present, the pineapple odor of its ethyl ester will be perceived.

Butyric acid when present in the amount of half a gramme per mille gives a tawny-yellow color with ferric chloride. Where the acid is present in considerable amounts, it may be distinguished by the odor of the contents.

Acetic acid may occur in the gastric contents in the presence of abnormal fermentation of carbohydrates. It is never present in the normal contents after an Ewald breakfast. It is produced by the action of a unicellular organism (the mycoderma aceti) upon the food.

The test for acetic acid is as follows: Ten cubic centimetres of the contents are shaken with 50 c. c. of ether, the ether drawn off and evaporated, and the residue dissolved in water. This aqueous solution of the ethereal extract is neutralized with sodic-hydrate, and a few drops of 10 per cent. neutral ferric chloride added. If acetic acid be present, a deep red color results. The acid may also be discovered by heating the contents with alcohol and sulphuric acid; the ethyl ester is formed, which can be recognized by the odor. When acetic acid is present in pathological amount, it can be recognized in the odor of the contents.

SUMMARY.

In summary, the chemical analysis of the gastric contents is conducted as follows:

- (1) Reaction tested with litmus.
- (2) Free acid is tested for with Congo red.
- (3) Test for free HCl with phloroglucin-vanillin. If negative or doubtful with this reagent, test with Boas reagent, 00 tropocolin, Töpfer's reagent.
- (4) Test for lactic acid, De Jong method.
- (5) Test for butyric acid.
- (6) Test for acetic acid.
- (7) Measure off 10 c. c. of the mixed contents; to this add two to three drops of phenothalein. To this mixture add decinormal soda-solution from a burette, testing a drop of mixture for free HCl by phloroglucin-vanillin after each addition of the soda. When a drop fails to give the Gunzburg test, record the reading of the decinormal solution present when the test was last obtained for the reading for total free HCl. Continue to add the decinormal solution to the same mixture, testing a drop after each addition with Congo-red paper for free acids and acid salts. Note the reading when the Congo red ceases to give even a slight brown color. At this point test a drop of the mixture

with a drop of one-fourth per cent. aqueous solution of alizarin. Continue adding the decinormal solution until a drop of mixture gives a pinkish-purple color with alizarin. Take this reading for the estimation of the total free acids and acid salts (B).

Where this alizarin test works, it is to be used as the index of these substances, the Congo test being simply an adjuvant test. The alizarin test is, as a rule, from one to two-tenths of a cubic centimetre decinormal soda-solution more delicate than the Congo (.036 to .072 gm. per mille). In many cases the alizarin test is not clear, and in such cases the Congo test must be relied upon. (See last number of JOURNAL, page 540.)

Continue to add decinormal solution until a pinkish-red color appears permanently in the mixture. The reading at this point indicates the total acidity (A). Subtract B from A = total combined acid (C). Add D to C = total secreted HCl (E). Subtract D from B = total organic acids *plus* acid salts (F). Repeat this analysis to this point with a fresh portion of contents.

(8) Test 10 c. c. of the contents for acid salts by Leo's method. Estimate free acids *plus* acid salts in 10 c. c. of contents after the addition of one gramme calcium carbonate (see page 541). Subtract total acid salts (G) from *this* estimate of the total free acids *plus* acid salts (B_2) = total free acids (H). Subtract total free HCl (D) from total free acids (H) = total organic acids (K).

(9) Place 50 mgm. of coagulated white of egg in 25 c. c. filtrate of contents at 40° C., and record time of disappearance of egg.

(10) Test for rennin and rennet zymogen by the tests given on page 542.

(11) If free HCl be absent, test for pepsin by the Hammerschlag method (page 541).

(12) If free HCl be absent, estimate the total combined HCl by the Mintz method (page 540).

The record for the second analysis for quantitative estimation of the total acidity, total for HCl, etc., may be taken as the final record. The quantitative tests for each of these substances may be made in separate portions of contents, if desired.

This is a summary of the complete chemical analysis of the gastric contents, as far as such analysis is suited to chemical work. It is unnecessary in many cases to apply the complete analysis.

If a given contents shows free HCl present, no lactic acid, normal total acidity, and a normal period of digestion of the egg albumin, it is, as a rule, safe to conclude that no abnormality which can be discovered by further chemical analysis is present. At the same time a more complete insight into the particular condition of the digestive apparatus in such cases may frequently be obtained by the estimation of the separate acid factors or the full analysis. Where the qualitative tests or the total acidity are abnormal further analysis is absolutely necessary — as the estimation of the amounts of separate acid factors and of the ferments.

II. RECORD OF THE ANALYSIS OF THE GASTRIC CONTENTS OF FIFTY HEALTHY INDIVIDUALS.

The characteristics of the normal gastric contents as investigated by the method described have been to some extent outlined in the description of the method. Stated collectively these characteristics are as follows:

Gastric contents expressed one hour after Ewald breakfast.

Total quantity of mixed contents, 36 to 200 c. c.

Total quantity of filtrate contents, 20 to 140 c. c.

Free hydrochloric acid, present.

Lactic acid, absent.

Butyric acid, absent.

Acetic acid, absent.

Proteids. Native proteids (albumin or globulin) are, as a rule, present in the filtrate in very slight traces. Acid albumin, present. Albumoses and peptones, present.

Carbohydrates. Starch is, as a rule, absent in the filtrate, but may be present. Erethrodextrin is frequently present. Dextrin and sugars are, in a majority of cases, the only carbohydrates present in the filtrate.

Total acidity of contents, 1.50 to 3 gm. per mille.

Total hydrochloric acid, 1.15 to 2.48 gm. per mille.

Total combined hydrochloric acid, 0.24 to 1.49 gm. per mille.

Total organic acids and acid salts, 0.20 to 0.88 gm. per mille.

Total free hydrochloric acid, 0.1 to 1.90 gm. per mille. Mean 1.12.

Period necessary to digest .005 gm. of coagulated egg albumin in 25 c. c. of contents, 2 to 3½ hours.

Pepsin, present. Quantity, 80 to 90 per cent. Hammerschlag method (page 541).

Rennin, present. Quantity, one-twelfth to one-fortieth dilution.

Rennet zymogen, present. Quantity, one-sixtieth to one one-hundred fiftieth dilution (by Friedenwald's tables, referred to on page 542).

The data just given are taken directly from the collected results of a series of investigations of the normal digestion which I have this year conducted at the Harvard Medical School.⁷⁴ The subjects of the investigation were healthy young men between the ages of seventeen and thirty years, students at the school. The number of individuals examined was fifty. Such cases only were taken as had no symptoms of digestive disturbance at the time of examination, and no history of chronic or intermittent dyspepsia.

The investigations were conducted in the following manner: Each man took an Ewald test breakfast, consisting of one baker's roll and 300 c. c. of water in the morning, after a fast of twelve hours. One hour later the stomach-tube was passed and the gastric contents expressed by the Ewald method (page 538). The expressed contents were then subjected to an investigation after the method described in this paper summarized on page 566.

In each of the fifty cases the following determinations were made:

- (1) Total quantity of mixed contents.
- (2) Total filtrate.
- (3) Presence of free hydrochloric acid.
- (4) Presence of lactic acid.
- (5) Total acidity.
- (6) Total hydrochloric acid.
- (7) Total free hydrochloric acid.
- (8) Total combined hydrochloric acid.
- (9) Total organic acids and acid salts.
- (10) Presence of starch, of erethrodextrin, of dextrin.
- (11) Presence of native proteids, of acid albumin, of albumoses or peptones.

In each of fifteen cases, in addition to the above, these determinations were made:

- (12) Presence of butyric acid.
- (13) Presence of acetic acid.

⁷⁴ The data in regard to the pepsin and the rennin must be excepted from this statement. These are taken from the observations referred to on pages 541, 542, in the last number.

(14) Period necessary to dissolve five milligrammes of coagulated egg albumin in 25 c. c. of filtrate of contents at 40° C.

(15) Total amount of acid salts.

(16) Total organic acid.

The scheme employed in the analyses was that given in the summary of the method on page 566.

In testing for free HCl, all four of the reagents mentioned in the detail of the method were used in order to test their relative delicacy and applicability.

The test used for lactic acid was the De Jong test.

The much-used Uffleman test, as also the Peuzolt modification of this, were both used in each case, in order to test the relative accuracy of these tests by the De Jong.

The quantitative estimations were made in each case both upon the mixed contents and upon the filtrates. The method used in the quantitative work is that detailed in the description as the color-analysis method (page 539).

It is clear that the results obtained in this way are of value chiefly for comparative work. For example, the estimation of the total free hydrochloric acid is slightly less than the actual amount present, as the limits of the Gunzburg reaction test are at best .05 gm. per mille. In the estimation of the total organic acids *plus* acid salts, by the subtraction of the total free hydrochloric acid from the total free acids *plus* acid salts, this .05 gm. per mille of HCl must therefore be included in the total of organic acids *plus* acid salts, making this total slightly too high. But such an error in the absolute amounts does not affect the value of the results for comparative work since this error is a constant in all results obtained by this method.

The results in the fifty cases fall within regular and fairly circumscribed limits admitting of a definite classification.

The qualitative results, as regards the mineral and organic acids, are absolutely regular.

The quantitative results show a fairly wide range of variation in the different cases; excepting in one case (Case 17), however, these results correspond to a definite type.

The summary of results in the cases is as follows:

(1) Total quantity of contents: mean, 110 c. c.; minimum, 35 c. c.; maximum, 220 c. c. Twenty-five cases gave a quantity of 100 c. c. or more.

(2) Total quantity of filtrate: mean, 110 c. c.; minimum, 20 c. c.; maximum, 140 c. c. Eight cases gave 100 c. c. or more.

(3) Free hydrochloric acid. Present in all cases.

(4) Lactic acid. Present in no case.

The Uffleman test was obtained from the crude filtrate in eight cases.

The Uffleman test was obtained in the ethereal extract of the contents (Uffleman-Peuzolt test)⁷⁵ in two cases, both of which had given the test in the crude filtrate. The De Jong test was obtained in no case. This would indicate that there were present in the contents in eight cases substances not lactic acid which to some extent simulated the test for this substance in the filtrate. In two cases only were these substances soluble in ether.

Butyric acid. Present in no case (15 cases).

Acetic acid. Present in no case (15 cases).

Proteids. Native proteids. Present in slight trace in 46 cases.

⁷⁵ Deutsches Archiv. f. klin. Med., 1893-94.

Acid albumin. Present in all cases in filtrate.
Albumoses or peptones (Biuret reaction). Present in all cases.

Carbohydrate. Starch present in six cases in filtrate. Erethrodextrin present in 15 cases. Dextrin present in 27 cases.

QUANTITATIVE ESTIMATIONS.

MIXED CONTENTS.

	Mean. per mille	Max. per mille	Min. per mille
Total acidity of mixed contents	2.18 gm.	3.00 gm.	1.50 gm.
Total hydrochloric acid	1.66	2.48	1.15
Total free hydrochloric acid ⁷⁶	1.12	1.90	0.09
Total combined hydrochloric acid ⁷⁶	0.57	1.49	0.24
Total organic acids and acid salts	0.59	0.88	0.20
Total organic acids (15 cases)	0.45	0.61	0.15
Total acid salts (15 cases)	0.14	0.27	0.08

FILTRATE.

Total acidity of filtrate	2.04 gm.
Total hydrochloric acid	1.48
Total free hydrochloric acid	1.07
Total combined hydrochloric acid	0.41
Total organic acids and acid salts	0.56

A comparison of the quantitative results of the mixed contents and the filtrates shows, as you see, a lower average total acidity in the filtrates. This difference appears from the results to be due principally to the smaller amount of combined acids which are present in the filtrates, the free acids both mineral and organic being practically the same in both contents and filtrates.

In several cases the total acidity of the contents and filtrates was the same; in all other cases the filtrate total was less. In one case the difference of the total acidity of contents and filtrate was 1.33 gm. per mille; in one case .56 per mille; in all other cases it was less than this. These examples serve to demonstrate the necessity of performing the quantitative tests with the mixed contents and not with the filtrates, as has been advised by several investigators. On this point my results are in accord with those of Martius and Luttke in their investigations of this subject.⁷⁷ The work of these authors shows, in addition, that different filtrates from the same contents give varying results.

The results of the investigation in individual cases may be seen in the following analysis, which I have taken from the fifty analyses:

CASE I. Total quantity of mixed contents, 150 c. c.

Free hydrochloric acid, present.

Lactic acid, absent.

Butyric acid, absent.

Acetic acid, absent.

Albumin, slight trace. Acid albumin, albumoses or peptone, present.

Starch, absent, erethrodextrin, present.

Total acidity, 2.47 gm. per mille.

Total hydrochloric acid, 2.03 gm. per mille.

Total free hydrochloric acid, 1.37 gm. per mille.

Total combined hydrochloric acid, 0.66 gm. per mille.

Total organic acids, 0.35 gm. per mille.

Total acid salts, 0.11 gm. per mille.

Total quantity of filtrate, 105 c. c.

Total acidity (filtrate) 2.30 gm. per mille.

Total free hydrochloric acid, 1.37 gm. per mille.

⁷⁶ This low record of free HCl was found in one case (Case 17). The next lowest record was .1 gm. per mille. This Case 17 also gave the high combined acid record 1.49 gm. per mille, also the highest difference between contents and filtrate 1.33 gm. per mille. The total acidity and the qualitative results were normal. I have records of several pathological cases with a low free HCl like this case, which were relieved by administration of HCl. So low a record is not therefore always normal.

⁷⁷ Martius u. Luttke, Magensaur d. Menschen, loc. cit. See also on this subject Giegler u. Blas, Zeitschr. f. klin. Med., Bd. xx; and Ewald, Zeitschr. f. klin. Med., Bd. xx.

Total combined hydrochloric acid, 0.40 gm. per mille.

Total organic acids, 0.40 gm. per mille.

Total acid salts, 0.10 gm. per mille.

Period necessary to dissolve .005 gm. coagulated egg albumin in 25 c. c. of filtrate at 40° C., 2½ hours.

CASE II. Total quantity mixed contents, 205 c. c.

Free hydrochloric acid, present.

Lactic, butyric, acetic acid, absent.

Albumin, present.

Starch and erethrodextrin, absent. Achrodextrin, present.

Total acidity, 2.54 gm. per mille.

Total hydrochloric acid, 1.82 gm. per mille.

Total free hydrochloric acid, 1.15 gm. per mille.

Total combined hydrochloric acid, 0.67 gm. per mille.

Total organic acids, 0.45 gm. per mille.

Total acid salts, 0.27 gm. per mille.

Total quantity filtrate, 135 c. c.

Total acidity, 1.98 gm. per mille.

Total free hydrochloric acid, 1.20 gm. per mille.

Total combined hydrochloric acid, 0.22 gm. per mille.

Total organic acids, 0.37 gm. per mille.

Total acid salts, 0.19 gm. per mille.

Period of dissolution of egg albumin, 2¾ hours.

CASE III. Total quantity mixed contents, 55 c. c.

Free hydrochloric acid, present.

Lactic acid, absent. Lactic acid test obtained in this case by Uffleman test on crude filtrate also in ethereal extract of contents (Uffleman-Penzolt) but not by De Jong method.

Butyric and acetic acid, absent.

Albumin, present.

Starch, present.

Total acidity, 2.18 gm. per mille.

Total hydrochloric acid, 1.38 gm. per mille.

Total free hydrochloric acid, 1.06 gm. per mille.

Total combined hydrochloric acid, 0.32 gm. per mille.

Total organic acids, 0.64 gm. per mille.

Total acid salts, 0.16 gm. per mille.

Total quantity filtrate, 28 c. c.

Total acidity, 2.03 gm. per mille.

Total free hydrochloric acid, 0.95 gm. per mille.

Total combined hydrochloric acid, 0.32 gm. per mille.

Total organic acids, 0.60 gm. per mille.

Total acid salts, 0.16 gm. per mille.

CASE IV. Total quantity mixed contents, 128 c. c.

Free hydrochloric acid, present.

Lactic acid, butyric and acetic acid, absent.

Albumin, absent.

Starch and erethrodextrin, absent. Achrodextrin, present.

Total quantity filtrate contents, 50 c. c.

Total acidity, 1.72 gm. per mille.

Total hydrochloric acid, 1.31 gm. per mille.

Total free hydrochloric acid, 0.87 gm. per mille.

Total combined hydrochloric acid, 0.44 gm. per mille.

Total organic acids and acid salts, 0.41 gm. per mille.

Period of dissolution of egg albumin, 3½ hours.

CASE V. Total quantity mixed contents, 60 c. c.

Free hydrochloric acid, present.

Lactic acid, absent. Test obtained in crude filtrate with Uffleman's test but not in ethereal extract or De Jong test.

Albumin, present.

Erethrodextrin, present.

Total quantity filtrate, 35 c. c.

Total acidity, 2.16 gm. per mille.

Total hydrochloric acid, 1.61 gm. per mille.

Total free hydrochloric acid, 1.37 gm. per mille.

Total combined hydrochloric acid, 0.66 gm. per mille.

Total organic acids and acid salts, 0.55 gm. per mille.

CASE XVII. Total quantity mixed contents, 60 c. c.

Free hydrochloric acid, present.

Lactic, butyric and acetic acid, absent by all methods.

Albumin, present. Albumoses or peptones, present.

Achrodextrin, present.

Total acidity, 2.12 gm. per mille.

Total hydrochloric acid, 1.58 gm. per mille.

Total free hydrochloric acid, 0.09 gm. per mille.

Total combined hydrochloric acid, 1.49 gm. per mille.

Total organic acids and acid salts, 0.53 gm. per mille.

Total quantity filtrate contents, 25 c. e.

Total acidity, 0.79 gm. per mille.

Total free hydrochloric acid, 0.07 gm. per mille.

Total combined hydrochloric acid, 0.21 gm. per mille.

Total organic acids and acid salts, 0.51 gm. per mille.

A comparison of these results with those of other investigators shows a general agreement, except in regard to two conditions. These conditions are:

(1) The total quantity of gastric contents.

(2) The condition of the carbohydrate digestion in the stomach.

The total quantity of the gastric contents expressed one hour after the ingestion of an Ewald test breakfast from the normal stomach is placed by most writers on the subject of gastric disease as lying between 25 and 60 c. c. (Rosenheim, 25 to 60 c. c.; Leo, 25 to 60 c. c.; Hammerschlag, 30 to 40 c. c.).⁷⁸

I have been unable to find any report of any definite sets of observations to serve as a basis for this generally accepted statement. The results are undoubtedly taken from the large number of cases these observers have examined in clinical work.

These writers say further, that a quantity of expressed contents of over 100 c. c. in a given case is suggestive of some affection of the motility of the stomach or of stenosis of the pylorus.

Boas states in his text-book that the total quantity of the filtrate upon the contents obtained one hour after the Ewald breakfast averages 40 c. c. in the normal stomach. The normal limits of variation he places as 15 c. c. each way.⁷⁹

He gives as the bases of his statement the results of the investigation of eight cases.

The results in the fifty cases which I have investigated are as follows:

The total quantity of the mixed contents expressed one hour after the Ewald test breakfast averaged 110 c. c.

The minimum amount was 35 c. c.

The maximum amount was 205 c. c.

Twenty-five cases showed a quantity of over 100 c. c.⁸⁰

The total quantity of the filtrate averaged 66 c. c.

The minimum was 20 c. c. The maximum, 140 c. c.

Eight cases showed a total filtrate of 100 c. c. or more.

These results differ considerably from those of Boas and from the statements of the other writers upon the subject.

They increase the limits of the normal variation and definitely contradict the conclusion that a total quantity, or even a total filtrate of the gastric contents of over 100 c. c. is indicative or suggestive of some pathological condition.

In regard to the condition of carbohydrate digestion in the normal stomach, the conclusion given by Ewald in his text-book is confirmed or acquiesced in, in practically all the text-books upon the subject.⁸¹ Ewald's conclusion is that in the filtrate of the gastric contents expressed one hour after the Ewald test breakfast from the normal stomach, the starch is all transformed to

achrodextrin. The presence of a blue color with the iodine-test (starch) or a purple color (erethrodextrin) he considers indicative of hyperacidity of the contents.

In the fifty cases which I investigated, starch was present in the filtrate in six cases, erethrodextrin in fifteen cases, achrodextrin in twenty-seven cases.

The evidence of these results warrants the conclusion that erethrodextrin or even starch may be present in the filtrate of the contents of the normal stomach one hour after the Ewald test breakfast.

In regard to the qualitative results for free hydrochloric and for organic acids all authors are in agreement.

In regard to the quantitative results there is practical agreement. Thus for total acidity we get the following set of figures:

TOTAL ACIDITY.		Per mille.
Ewald ⁸¹	.	1.30 to 2.40 gm.
Leo ⁷⁸	.	0.73 to 2.19
Friedenwald ⁸²	.	1.40 to 2.29
Hewes	.	1.50 to 3.00
FOR TOTAL FREE HYDROCHLORIC ACID.		
Mintz ⁸³	.	0.50 to 1.00
Friedenwald ⁸²	.	1.39 to 1.75
Hewes	.	0.10 to 1.90

For the test of digestive capacity with egg albumin Jaworski found that five milligrammes of coagulated egg albumin dissolved in 25 c. c. of filtrate of normal gastric contents in two to three hours at 40° C.

In considering these results in my cases two facts must be borne in mind: (1) that the results were obtained exclusively upon healthy young men; (2) that the individuals utilized were all accustomed to partake of a hearty American breakfast at the hour at which they took the test meal.

In what way and to what extent these facts have influenced the results, it is impossible to determine. It is probable, however, that results obtained from individuals of all ages and both sexes would differ somewhat from these.⁸⁴

These results were obtained upon individuals many of whom had never experienced the passing of the stomach tube. Some observers consider results obtained at the first passage of the tube as inaccurate, owing to the effect of the experience upon the nervous-control system of the patient. I have examined the contents obtained from these same individuals on subsequent occasions, in a considerable number of cases, and have found the general averages and limits the same.

When all is said, however, data of this kind can be used as control data in a general way only. For, as is well known in matters of physiological function, each individual is to a certain extent a law unto himself.

PERILS FROM ELECTRICITY.—A man was killed in Philadelphia last week by a shock of electricity while he was looking in a shop window. It was raining and he was holding an umbrella with a steel rod in it over his head. Above him was an electric arc light. The end of the umbrella rod touched the iron frame of the lamp and a current of electricity passed through his body to the iron covering of a coal shaft in the sidewalk, killing him instantly. A man was killed in a similar way on Eighth Avenue in New York about three years ago. — *Medical Record*.

⁸⁴ Abstract in *Boston Journal of Medical Sciences*, No. 11, 1897.

A CASE OF CHOLECYSTITIS DUE TO THE TYPHOID BACILLUS.

BY MARK W. RICHARDSON, M.D., BOSTON.

From the Pathological Laboratory of the Massachusetts General Hospital.

ABOUT April 1, 1897, I had referred to me by Dr. Maurice H. Richardson two specimens for examination. The first consisted of about half a pint of dirty, brownish fluid, and the second was a swab soaked in that fluid for bacteriological investigation. The fluid had been evacuated from a gall-bladder which was the seat of a purulent inflammation, and which was distended by the impaction of a biliary calculus in the cystic duct.

I found the fluid to have the following characteristics: it was dirty-brown in color, cloudy and slightly viscid. The reaction was alkaline; the specific gravity 1.018; albumin one-half per cent.; bile reaction very faint. There was much reddish-white, granular sediment. Microscopically, the sediment showed much normal blood (operation?); many small, round, fatty-degenerated cells; considerable numbers of large, squamous epithelial cells; many bacilli in large clumps.

I next proceeded to the bacteriological examination of the swab above mentioned, sweeping it thoroughly over the surface of two blood-serum tubes. After twenty-four hours in the incubator each tube showed about half-a-dozen round, semi-transparent, whitish-gray, moist colonies of considerable size. Microscopically the growth was found to be made up of what was apparently a pure culture of a short, stout bacillus with rounded ends. The organism varied considerably in size; occurred most often alone, but sometimes grew out into chains of from three to six elements; in short, the bacillus belonged apparently to the colon group, and was very probably the colon bacillus itself. I was much surprised, however, when, after further cultivation upon differential media, the organism showed all the characteristics of the typhoid bacillus: (a) It was quite motile. (b) It produced no coagulation of litmus-milk, and only a very faint acid reaction. (c) It produced no gas when grown upon sugar-agar. (d) It showed no production of indol when grown in peptone solution. (e) It grew characteristically, without liquefaction, upon gelatin slant and stab cultures. (f) It showed no visible growth upon potato. (g) It did not grow at all upon solution No. 1 of Proskauer and Capaldi. Upon solution No. 2 of the same authors it produced a marked acid reaction. (h) It showed the specific reaction of Pfeiffer when treated with typhoid serum.

The discovery of the typhoid organism in the purulent exudate added much to my interest in the case, and led me to inquire more carefully into the previous history. Dr. Chandler, of Townsend, Mass., the attending physician, gave me the following account of the case:

Five weeks previous to operation the patient, Mrs. P., an elderly lady, first came under observation with symptoms of an acute cystitis. This condition improved much after a week of appropriate treatment.

Four weeks before operation the temperature and pulse began to rise steadily. There was also nausea with considerable pain and tenderness in the right iliac region. The patient had a typhoidal look. The case was thought to be possibly one of appendicitis, and

the patient was seen by Dr. M. H. Richardson, who advised waiting.

Two weeks before operation the temperature was still elevated. There was some pain in the right chest, and considerable cough with rusty sputum. No enlargement of the spleen was noted, and no rose-spots were seen. At this time a firm, rounded tumor was first made out below the ribs on the right side, and at about the level of the anterior superior spine of the ilium. The mass was very tender and painful. Examination under ether by Dr. Chandler, of Townsend, and Dr. Stimson, of Fitchburg, showed that the tumor was quite movable, and apparently extended through to the back. A probable diagnosis of pyo- or hydro-nephrosis was made. Urine was said to be negative.

One week before operation the temperature had dropped to about 100°, but the tumor had become much larger, with considerable increase in pain and tenderness.

At the time of operation no positive diagnosis was made, but the lesion was thought to be a pyo-nephrosis or an acute cholecystitis. A short incision in the back, however, showed the right kidney to be normal. An oblique cut was then made in front over the gall-bladder, which was found excessively distended. The gall-bladder was first aspirated, then freely incised. Impacted in the cystic duct, and removed with great difficulty, was an elongated, cylindrical gall-stone with a smooth surface and rounded ends.

Since the operation the progress of the patient has been satisfactory. The opening into the gall-bladder is gradually closing in, and there has been great increase in weight and strength.

A week after the operation, at my request, Dr. Chandler sent me a specimen of the patient's blood (dried on paper), and a small portion of a stool. I could obtain no typhoid serum-reaction with the blood, however, nor did bacteriological cultivation from the stool by the Capaldi method show any typhoid bacilli. In connection with this attempt it is interesting to note, nevertheless, that, although the dried blood caused no clumping of typhoid bacilli, the fluid from the gall-bladder, when filtered and added, in proper proportion, to an independent typhoid culture, caused a well-marked reaction. Indeed, if we look once more at the sediment of the inflammatory exudate, I think we must regard the large clumps of bacilli which we find there, as evidence of a gigantic serum-reaction which has taken place spontaneously in the gall-bladder.

From all the evidence obtainable in this case it seems clear that there was a typhoidal infection of the gall-bladder associated with the presence of a gall-stone in the cystic duct. Was this infection primary or secondary?

A primary infection of the gall-bladder by the typhoid bacillus has, as far as I know, never been described. *A priori*, it is perfectly possible to imagine such a localized infection, but in the absence of post-mortem evidence, such a supposition can have but little value.

On the other hand, a cholecystitis as a sequel to typhoid fever, as has been exhaustively shown by Dr. A. L. Mason¹ is of quite frequent occurrence, and it is in this latter category that I would place the present case. For, as it seems to me, the history—four to five weeks of continued fever, abdominal pain and tenderness, typhoidal aspect, bronchitis—suggests

¹ Boston Medical and Surgical Journal, May 13, 1897.

distinctly a previous typhoidal invasion of the intestinal tract. Nor would the fact that the blood, one week after the beginning of convalescence, gave no typhoid reaction deter me from such a conclusion. For, as is well known, the blood-conditions necessary for the serum-reaction may be present upon one day and absent the next, or they may entirely disappear with or even before the fever, so that the value of a single negative result is not great.

As we look over the increasing literature upon the subject of cholecystitis as a sequel to typhoid fever, I think we cannot fail to be impressed with its great importance. Especially striking are the observations of Chiari, who found typhoid bacilli in the gall-bladders of 19 out of 22 typhoid cadavers. Moreover, out of these 19 positive cases 13 showed a condition of actual inflammation.

We see, therefore, that, in typhoid fever, the bile, far from being antagonistic to the growth of the typhoid bacillus, actually becomes a medium in which it reproduces itself rapidly. Furthermore, that the bacilli may persist for considerable lengths of time in the gall-bladder is shown by the case of Gilbert and Girode, and that of Dupré (quoted by Mason, loc. cit.), in which cholecystotomy five and six months after typhoid fever showed pure cultures of the typhoid bacillus.

At the Massachusetts General Hospital during the last nine months ² cultures from the gall-bladder were made at three autopsies of typhoid patients, and in every case typhoid bacilli were demonstrated. Two of these cases were uncomplicated typhoids. The third was unusual in that it was combined with a general tuberculosis. This patient was admitted to the hospital November 2, 1896, and passed through what was apparently a typhoid fever lasting from three to four weeks. During this time a suspicious patch of consolidation was detected in one lung, but examination of the sputum failed to reveal any tubercle bacilli. At the end of four weeks, when convalescence was apparently about to begin, irregular fever with cough, persistent vomiting and rapid emaciation set in, and death followed in six weeks. At the autopsy the following pathological conditions were found: chronic tuberculosis of the lungs, with cavity formation; chronic miliary tuberculosis of the liver, spleen and kidneys; chronic tubercular salpingitis, with localized abscess formation and circumscribed peritonitis; ulceration of the ileum, partly tubercular and partly typhoidal; tuberculosis of the mesenteric, retro-peritoneal, and bronchial lymph glands, etc. Typhoid bacilli were found in the bile, liver, kidney, and the pus of the pelvic abscess.

I could find no record as to the presence of a typhoid serum-reaction during the life of the patient, but a specimen of blood obtained at the autopsy, added to a typhoid culture, gave a well-marked positive result.

This case, therefore, not only illustrates the power of the typhoid bacillus to grow in the gall-bladder and to persist there for several weeks after the end of the proper typhoidal infection, but also demonstrates the possibility of a simultaneous double infection of the intestine with the bacilli of typhoid fever and tuberculosis. A very similar case has been reported recently by Guinon and Meunier.³

In the light of what has been said I think the possibility of a complicating cholecystitis should be borne strongly in mind in the later stages of any case of typhoid fever.

Given such an inflammation of the gall-bladder, and having failed to relieve the condition by medical methods, we should avoid the dangers of rupture or perforation by early resort to surgical interference.

RECORD OF TWO CASES OF BEGINNING PULMONARY TUBERCULOSIS TREATED WITH SUBCUTANEOUS INJECTIONS OF KOCH'S TUBERCULIN T. R.¹

BY ELBRIDGE G. CUTLER, M.D., BOSTON.

THROUGH the courtesy of Mr. Humes Hall, the Boston representative of John T. Milliken & Co., manufacturing chemists of St. Louis, Mo., I was enabled to give the injection of Koch's Tuberculin T. R. prepared by them in their laboratory to the following two cases of early pulmonary tuberculosis. The solutions were freshly prepared for each injection according to the printed directions. The injection was invariably given between or below the scapulae. Each injection was given with an ordinary subcutaneous syringe after the first few trials of the antitoxin syringe of Williams. This necessitated filling the barrel of the syringe three times for each injection on an average, and the introduction of the needle into a new place each time.

There was no abscess produced in the eighty or more punctures which were made during the treatment of the cases. The only complaint was of a slight soreness in one case in the neighborhood of the injections on about the sixth day of treatment. The injections were also made in three other cases, but as these cases were not suitable to the treatment, from too advanced a stage of the tuberculous process, they have not been included in this report. No constitutional symptoms were observed after the injections in these two cases, nor did the temperature more than once rise as much as one degree Fahrenheit above its usual course. As a rule, the cough and local signs progressively diminished, the amount of the expectoration lessened, and the patient felt progressively better in all the cases in which I have used the Tuberculin T. R., though in the unfit cases (too advanced a stage of disease) emaciation and an extension of the disease kept steadily on.

Professor Koch states that only cases of beginning tuberculosis should be treated with Tuberculin T. R.; that the initial injection should not exceed one five-hundredth of a milligramme; that the temperature should be watched carefully; and that no reaction fever of more than one-half a degree Centigrade should be allowed. If the fever due to the injection is more, the dose should be lessened; otherwise, every other day an injection may be given and the dose doubled each time till one has given fourteen injections or a final dose of sixteen milligrammes. It sometimes happens that more than the usual number of injections is required, or they may have to be made less often or smaller in amount each time. In order that a proper oversight of the patient may be insured and a careful record of the temperature taken it is necessary that the patient should be either treated in a hospital or have the ser-

² I am indebted to Drs. Fitz and Wright, of the Massachusetts General Hospital, for permission to publish these cases.

³ Rev. Mens. des Mal. de l'Enfance, April, 1897.

¹ Read before the Suffolk District Medical Society, October 30, 1897.

vices of a trained nurse at home during the entire time of the treatment.

CASE I. J. A. W., teamster, aged seventeen, born in Nova Scotia, residing in Roxbury, entered the Massachusetts General Hospital August 9, 1897.

The family history was unimportant. His personal history embraced an attack of measles and whooping-cough in childhood, and an occasional cough since on catching cold, which was speedily recovered from. He used no tobacco nor alcoholic drinks, but took five cups of tea a day.

His present illness began on the fourth instant, when he got wet while at work, and had a cough accompanied by bloody expectoration, which still continued. There was no pain on taking a long breath, no chill, no stitch in the side. He admitted that he had been ill for a month or more, with loss of appetite, slight cough, and felt pretty "seedy," though he kept on working.

His temperature on entrance was 100.4° F., pulse 80, respiration 32. He was well developed, but thin. The pupils were equal and reacted to light. Tongue slightly coated. The heart was rapid in action, otherwise not abnormal. Abdomen showed nothing unusual. Deep and superficial reflexes normal. Lungs gave a few moist, medium fine râles over the left chest, more marked in the axillary region. An occasional râle on the right side. No change in the respiratory and voice sounds. Urine of normal color, acid, 1.032 specific gravity; no diazo reaction; no bile, sugar or albumin. The blood-count gave 9,800 whites. Hemoglobin, 102.5.

August 10th. Much cough in the afternoon and evening, with large amount of bright-red and some dark, bloody expectoration. Hospital cough mixture.

August 11th. Cough and expectoration somewhat diminished. More comfortable.

August 12th. Less expectoration, blood darker. More comfortable. Tubercle bacilli found in abundance in the expectoration, also pneumococci. Urine normal in color, acid, 1.026; chlorides normal; no diazo; no bile, sugar or albumin; sediment contained calcic oxalate crystals, a few blood globules, leucocytes and round epithelium cells.

August 15th. More hemorrhage in the early morning.

August 18th. Nucleinic acid five-per-cent. solution, ten minims, three times a day.

August 20th. Considerable hemorrhage last night and this morning. Nucleinic acid increased to twenty minims, three times a day.

August 22d. Considerable hemorrhage. Nucleinic acid increased to thirty minims *ter die*.

August 25th. As he had made no improvement, the nucleinic acid was omitted and 1.6 mg. of Milliken's Tuberculin T. R. was injected subcutaneously, according to Koch's directions.

August 26th. There was no reaction from the Tuberculin T. R. injection. He rested quietly all day.

August 27th. Feels well.

August 28th. Injection of 3.2 mg. Milliken's Tuberculin T. R.

August 29th. There has been a gradual improvement since the injection. Says he feels well.

August 30th. Injection of 3.6 mg. Milliken's Tuberculin T. R. Sat up. There was a slight rise in temperature of about one degree to nearly 100° F. There was no disagreeable after-effect. Feels very well.

September 1st. Injection of 5.6 mg., or a little less, as the syringe did not work well. The temperature reached 100° F. about six hours after injection, but the patient felt perfectly well.

September 3d. Injection of 1.6 mg. Out doors in the yard. Feels much stronger. No rise in temperature from the injection.

September 5th. Injection of 3.2 mg. Complained of pain in the region of injection. No swelling or visible change in the skin at this point.

September 6th. Has gained six pounds in weight during the past week and looks very much better. Aside from a simple cough mixture, has had only the injections.

September 7th. Tuberculin T. R. injection of 6.4 mg., no reaction; September 9th, one of 1.6 mg., no reaction, doing well; September 11th, 3.2 mg., no reaction; omitted cough mixture; September 13th, 1 mg.; September 15th, 2 mg.; September 17th, 4 mg.; September 19th, 8 mg.

September 21st. Tuberculin T. R. injection of 16 mg., which was followed by a chill and rise of temperature to 99.5° F., though the patient was not bothered by it. The patient had been out in the yard daily for the greater part of the day since the 3d instant, and lately had visited his friends outside every day as well.

September 27th. Since the injection of Tuberculin T. R. was begun, the patient has steadily improved in every way and was discharged to-day "much relieved." There was no expectoration, no cough, and there had been no opportunity to get any sputum for examination for some days. There were no physical signs in the chest on discharge.

CASE II. E. B., student, aged twenty-four, single, born in Prince Edward's Island, living in Cambridge, entered the Massachusetts General Hospital, September 2, 1897, with an unimportant family history.

Habits. One cup of tea and one cup of coffee *per diem*, no alcoholic drinks.

Previous History. Measles, whooping-cough and scarlet fever as a child. A pulmonary hemorrhage last winter.

Present Illness. Twelve days ago pulmonary hemorrhage without cause. Since then eight or nine hemorrhages, the last one to-day.

Examination. Pulse 96, temperature 101.8° F., respiration 24. Well developed and nourished. Pupils react equally. Tongue slightly coated. Pulse of good volume, fair tension, not easily compressible. Lungs: on the left side, under the clavicle, a few moist râles are heard at the end of inspiration; slight dullness on the right side, but no râles. Heart apex in the fifth interspace inside mamillary line; no murmurs; aortic second sound not accentuated; pulmonary second sound accentuated. Abdomen not distended nor tympanitic. Liver not enlarged. Spleen not felt. Abdominal and patella reflexes normal. Urine of normal color, acid, 1.028; no albumin, bile, sugar or diazo reaction. Hemoglobin 100. Many tubercle bacilli found in sputum.

September 3d. Injection subcutaneously of 3.6 mg. Milliken's Tuberculin T. R. No medicines otherwise.

September 4th. No hemorrhage. Resting very quietly all day. Mouth dry.

September 5th. No hemorrhage. Feels better. Injection of 3.6 mg. Tuberculin T. R. which gave no reaction.

September 6th. No respiratory murmur on the

right side behind, above the angle of scapula. High pitched respiration in front on the same side as low as the third intercostal space and fine moist râles which disappear under examination.

September 7th. Injection of Tuberculin T. R. $\frac{3.6}{5.0}$ mg., no reaction. Many tubercle bacilli found in sputum.

September 9th. Injection of Tuberculin T. R. $\frac{3.6}{5.0}$ mg. Feels stronger. Still some expectoration. Slight cough.

September 11th. Much stronger. Injection of $\frac{3.6}{5.0}$ mg. Tuberculin T. R.; Bacilli not as numerous.

September 13th. Injection of $\frac{3.6}{5.0}$ mg. Tuberculin T. R. Improving all the time. Sat up.

September 15th. An injection of $\frac{3.6}{5.0}$ mg. Tuberculin T. R.; September 17th, one of $\frac{3.6}{5.0}$ mg.; September 19th, one of 1 mg. Much better. Has increased in weight markedly. Cough much less.

September 21st. Tubercle bacilli not so abundant. Injection of 2 mg. Tuberculin T. R.

September 23d. Injected 4 mg. Tuberculin T. R.; September 25th, 8 mg.; September 27th, 16 mg. Since the injection of Tuberculin T. R. was begun, the patient has steadily and uninterruptedly improved without other medication. He was discharged "much relieved" a few days after the last injection was made, with no cough, no expectoration and feeling well.

October 14th. Received a postal card from him, stating that he had gained six pounds in weight in the fifteen days he had been out of the hospital. He coughed scarcely at all, and "raised" absolutely nothing.

October 25th. Seen and examined. Had gained twelve pounds in weight since leaving the hospital. No cough, no expectoration. Feels perfectly well and looks splendidly. Careful physical examination of lungs was not made, as patient was in a hurry to go.

ALCOHOLIC STIMULATION IN CONTINUED FEVERS.¹

BY RICHARD C. CABOT, M.D.

WHAT are the indications for the use of alcoholic stimulants in such febrile diseases as typhoid, grippé, pneumonia or septicæmia?

There are many who regard the existence of one of these febrile diseases as of itself a sufficient reason for giving alcoholic stimulants. For example, in Wood and Fitz's "Practice of Medicine," it is laid down that "Alcohol in some form should be used in *every* case of typhoid *from the beginning*, unless there be some very strong reason for refusing it, as where there is a distinct heredity towards drunkenness." Many who might not agree to this course in typhoid believe in using alcohol in every case of pneumonia, whatever its nature, and in all severe septic and pyæmic processes, I should suppose that the majority of good practitioners in this vicinity would prescribe alcohol as a matter of routine. From this point of view the diagnosis once established, the exhibition of alcoholic stimulants is a matter of course.

On the other hand, there are in many modern textbooks signs of a reaction against this wholesale and routine use of stimulants. For instance, W. Gilman Thompson, in his new work on dietetics, says, "I am inclined to prescribe very much less alcohol than for-

merly"; and again, "The routine employment of alcohol in typhoid is to be deplored." Pepper, in the edition of 1894 of the "American Text-book of the Theory and Practice of Medicine," says, "Until recently, the symptoms of alcoholic over-action (in typhoid) were often mistaken for advancing debility, and regarded as an indication for still more free stimulation."

Of modern authorities I think Strümpell is the only one who distinctly disbelieves in the use of alcohol in any of the diseases above mentioned. Even in pneumonia he does not give alcohol except to patients who have become habituated to it before their illness. "We could never satisfy ourselves," he says, "of the often praised action of alcohol on the heart."

Between these two extremes — the routine use, and the absolute avoidance of alcohol in continued fevers — falls the practice of most of us. The usual opinion is that there are certain indications for the use of alcohol in such cases. What I want to bring out in this paper is that many of us are not as clear or as consistent as we ought to be as to just what we expect to gain by stimulation, and as to the reasons for its use in any particular case.

For example, I think that there is a fairly widespread impression among us that alcohol is itself directly inimical to the toxæmia which forms the chief danger in acute infections.

Does this impression rest on any satisfactory experimental basis? I have never heard of any such. If it could be shown that the use of alcohol increases the germicidal power of the blood, or the power of the kidney to excrete toxins, or precipitates them in the stomach, we should have a satisfactory reason for giving stimulants, as, for instance, most surgeons now give them in septic cases. There would then be good reason for giving stimulants even if they did *not* improve the heart's action, the digestion or any other function of the organism. But, so far as I know, there is no experimental evidence that the ingestion of alcohol *does* increase the antitoxic or bactericidal power of the blood, and there is a certain amount of evidence that so far from increasing the ability of the kidneys to excrete toxic products, alcohol has just the reverse effect. We know that alcohol precipitates snake poison in the stomach where it is excreted, but I am aware of no such evidence as regards other toxins.

I have heard surgeons and others express a belief that it is no harm to stimulate a septic patient even to the point of making him drunk. As to the wisdom of this course the following experiments are relevant:

(1) In the *Comptes de la Société de Biologie* for 1895 (p. 51) Wurtz and Hudels report experiments on 14 rabbits and 7 guinea-pigs which were given enough alcohol to make them drunk, and then killed, and their blood examined for bacteria. Over one-half the cases showed the presence in their blood of streptococci, colon bacilli, proteus vulgaris and various anaerobic organisms.

The control animals, to whom the same dose of alcohol had been given, recovered from its effects, showing that the inroad of bacteria in the autopsied cases was not due to any moribund condition from a lethal dose. They were simply drunk and not dangerously poisoned.

If large quantities of alcohol make bacteria enter the blood in animals, why may it not have a similar effect in sick men? Are we likely, then, to benefit a septic patient by making him drunk?

¹ Read before the Suffolk District Medical Society, October 30, 1897.

(2) Again, take the question of the excretion of toxins by the kidney. It is well known that in most acute infectious diseases, where the patient is doing well, the urinary toxicity is greatly increased, and this is taken to show that the kidneys are aiding in the fight against the disease by excreting the poisons produced by the infectious agent. Kellogg found that the use of alcohol, so far from increasing the urinary toxicity, greatly decreased it. I do not vouch for these results, but offer them for what they are worth. There is no doubt that cold bathing in typhoid does increase the urinary toxicity, as has been shown by Roque and Weill.

Apart from the question of the action of alcohol as an antitoxic or bactericidal agent, the following indications for using it in continued fevers are stated in most text-books:

(1) Persons long addicted to its use should not be deprived of it in febrile diseases. On this point there seems to be no disagreement.

(2) It may be the only form of food which the patient can and will take.

(3) Sudden collapse or great prostration from any cause is generally agreed to call for stimulation.

As to these three indications I think most physicians would agree. But the great majority of writers go further and recommend that —

(4) Any serious complication, such as hemorrhage or perforation in typhoid, severe nervous symptoms like delirium — in fact, anything that shows an especially severe case — should be considered an indication for stimulation.

(5) Persons over forty years of age and persons of feeble constitution are believed by most writers to need stimulation in case they catch any severe infectious disease, like typhoid or pneumouia.

On the other hand, Ringer's views on the use of alcoholic stimulants are copied into many text-books, and they conflict with the belief that a severe or complicated case or one occurring in a feeble person should always be treated with stimulants. Ringer says in substance: "If after the use of alcohol we see the pulse become slower, the skin and tongue moister, sleep better, nervous symptoms less marked, breathing less hurried, food better taken — the alcohol is doing good. *Not otherwise.*"

Now, if this be true, we cannot say that severe or debilitated cases need stimulation, but only that they may need it, or that they need it in case it turns out to do them good. Now, this is where I think many of us err. We do not watch the action of alcohol as we do that of other drugs which may do harm. We often give it as we might give malt, and not as we give digitalis or calomel. When we give a diaphoretic or a purgative, we look for its definite action; if we do not get it after a sufficient dose, we do not continue the drug. But I have repeatedly seen alcohol given whether any good effects appeared or not, with a general idea that it must be doing good since it is a food and a stimulant. But in many cases it does not act as a stimulant — in any dose; does not slow the pulse, moisten the tongue or decrease restlessness and delirium; and other food is so well taken that it is not needed as a food, yet we go on using it under a vague impression that it helps the patient to fight his disease, makes him feel better perhaps, and at any rate cannot do any harm. I want to enter a protest against such treatment, which I see constantly administered in our hospitals and else-

where. I believe with Pepper, that the symptoms of alcoholic poisoning are "often mistaken for advancing debility and regarded as an indication for still more free stimulation."

There is a pernicious idea which I have repeatedly heard advanced by prominent physicians, that if the smell of alcohol is not present on the breath, the amount of alcohol given must be doing good. But alcohol is not excreted solely by the lungs and its ill effects can be shown, as Ringer and others have pointed out, by other symptoms besides the smell of the breath.

In conclusion, it seems to me that what is most needed at the present time in order to improve our therapeutic use of alcohol is more experimental evidence on two points: (1) the effects of alcohol on the toxicity of the urine, and on the antitoxic and bactericidal power of the blood; (2) the effects of treating acute infectious diseases without alcohol.

I have often thought that therapeutic progress is seriously hindered by the fact that every case is given the best treatment known. I cannot account for the long persistence of the bleeding treatment except by supposing that since every patient was given the best treatment known, namely bleeding, physicians had no chance to see how the disease would do without the treatment. Similarly, at the present day, so few of us have ever seen a severe case of sepsis or pneumonia treated without alcohol that it is very possible that some of us may attribute to the disease (as Pepper says) symptoms really due to the treatment. I have often been struck with the close resemblance between delirium tremens and some of the symptoms of severe febrile cases treated with the best known alcoholic stimulation.

In 1864 A. L. Loomis treated 600 cases of typhus fever without alcoholic stimulants as an experiment. His mortality record was six per cent.; the previous record in the same epidemic in cases treated *with* stimulants was 22 per cent.

N. S. Davis claims to have treated 1,000 cases of typhoid fever without alcoholic stimulation, with a mortality of five per cent.

Kellogg, of Battle Creek, states that he has treated 82 cases of pneumonia without alcohol, with a mortality of 4.9 per cent.

Now, I am aware that statistics can lie, and I am not prepared to say, as Strümpell does, that we should give up alcoholic stimulation in fevers; but I do think that we need a broader experimental basis for our practice of and use of stimulants simply because the case appears very severe.

CONCLUSIONS.

(1) Alcohol, like other drugs, should be given to accomplish a definite therapeutic result, and if no signs of that result appear, the drug should be withdrawn.

(2) Experimental evidence is much needed:

(a) As to the effects of alcohol on the toxicity of the urine and the bactericidal power of the blood; (b) as to the result of treating acute febrile diseases without alcohol.

WOMEN SUE DRUGGISTS. — Two cases are now being heard in Brooklyn, N. Y., in each of which a woman is suing a druggist for \$5,000 and \$10,000 damages, respectively, for prescribing medicine which she alleges caused permanent injuries and impairment of health. — *Medical News.*

PNEUMONIA, TREATED BY HEAT OVER THE SPINE AND BY THE INHALATION OF PURE OXYGEN.

BY BEVERLY OLIVER KINNEAR, M.D., NEW YORK.

PNEUMONIA is a very fatal disease in old people, in broken-down constitutions from any cause, and also frequently in unusually strong people, from the very vigor of their circulation; a congestion of the active form in such cases often covering a larger area of lung and extending more rapidly unless promptly checked. Whether the germ theory of pneumonia be correct or whether it is not will not be discussed in this paper; but the disease as an inflammation, caused by abnormal conditions of the circulation, will be presented, and some reference made to the central nervous system and its agency in the generation of inflammatory troubles.

The treatment of pneumonia in the congestive stage, and that of red hepatization, by heat over the dorsal sympathetic ganglia is but little known as yet to the profession, though it has been occasionally brought to their notice during the past thirty years; while the proper use of properly combined oxygen given by inhalation, or by the rectum if necessary, will undoubtedly be the means of saving many lives which without it would certainly die. It is our object to demonstrate what heat so used will accomplish in this disease in its early stages, and give evidence of the soothing, supporting and life-restoring power of properly combined and prepared oxygen.

Pneumonia may be broadly divided into acute and chronic. The clinical course of the acute form is that of chilliness or rigor, followed by vomiting and sometimes convulsions, the last especially in children or epileptics.

The rise of temperature is exceedingly rapid in pneumonia, with crimson cheeks, and a pungency of the skin not noted in other inflammatory disorders.

There is no perceptible dyspnea, yet the rate of respiration is extraordinarily rapid. There may or may not be the rusty sputa with the cough; the nostrils dilate during inspiration, and the lips are of a slightly purplish color, due to insufficient aëration of the blood, and normal oxidation of the tissues.

Early and even violent delirium is common in extended pneumonic trouble, especially in neurotic subjects. There is pain in the majority of cases, and the usual pains, headache and loss of appetite common to all febrile complaints.

The physical signs in this early stage show restricted movement of the side affected, some increased vocal fremitus, and slight dulness over the affected part of the lung. There may or may not be crepitant râles in this congestive stage.

All of these signs are intensified in the stage of red hepatization. The right lower lobe is most frequently attacked, and usually only a portion of the lung is implicated; but it is apt to spread to other parts with great rapidity unless promptly checked. The physical signs and the clinical course denote both congestion and exudation into the air-cells, and infundibula.

The post-mortem appearances corroborate the physician's observation and examination. In the first stage, the lung is found massive, weighty and of a brownish-red color. Under the microscope the most manifest departure from health is observed in the dilated and twisted state of the arterioles of the alveolar walls, with minute points of extravasation beneath the

pleura, and in the connective tissue between the lobules. In the stage of red hepatization the lung is more solid and the infundibula and air cells are found full of inflammatory exudation.

Thus these three methods of investigation, two before and one after death, testify to the true conditions within the lung, or lungs, which constitutes a developing and developed pneumonia. From the testimony of these two or three important witnesses conjoined, it appears to the writer that the most efficient treatment in this early stage is to contract the arterioles in the inflamed area, as well as throughout the upper body, because from post-mortem appearances we know that in cases of pneumonia where much of the lung is involved there is also found effusion upon the pleural surface, pericarditis, and even the upper part of the peritoneum may be found covered with lymph; while delirium and cerebral meningitis may ensue.

How then may we successfully accomplish this much to be desired end?

We have found that very rapid and satisfactory results can be obtained by applying the spinal hot-water bag, or its equivalent in heat and moisture over the dorsal sympathetic ganglia. By the application of heat over these knots of nervous tissue in this region, we have over and over again, during the past sixteen years, subdued nearly all the acute forms of inflammation affecting the respiratory apparatus.

The accompanying cut gives a good idea of the double columned hot-water bag and illustrates the method of its application. Two rolls of flannel may be applied (being first dipped in water no hotter than 120° F.) instead of the hot-water bag; the space of one inch should be left between the rolls, so that the heat will not cover the spinal vertebrae direct. One yard of flannel, eight inches wide, rolled evenly from each end toward the centre until the space of one inch remains between the rolls, may then be sewed so that they will not unroll. They will answer if the hot-water bag is not at hand, and may be made the means of saving many lives in the earlier stages of all inflammations of the respiratory passages. They should be wrung out after dipping in water at 120° F., and then quickly applied between the shoulders, covered with a thick dry towel, and the patient told to press against them. The application when flannel is used should be changed every twenty minutes, until decided relief is obtained to the breathing, the pain, the flush of the face and the bounding pulse (which if reduced in speed and volume will at once lower the temperature). It may then be removed until there are signs of a renewal of the symptoms, when it can be reapplied, and will be found at once to check them. The hot-water bag used

in this way in active congestions and early inflammations will always reduce the temperature and the pulse, and excite the sweat glands to action, thus giving relief to the symptoms; evidencing also by auscultation a speedy progress toward recovery, and therefore a return to normal of the calibre of the pulmonary capillaries in the stage of congestion—and in the condition of red hepatization, a rapid resolution or reabsorption of the inflammatory exudation.

In bronchitis, in pneumonia alone, or accompanied by pleurisy, in acute laryngitis, and in the frequent pleurisy of phthisis, we have quickly controlled the inflammation by this means.

In some people we have found great prostration follow the rapid reversal of the inflammatory process in respiratory diseases; and we believe it to be due to some extent to the shock to the nervous system, both of the attack and also that caused by the sudden restorative change. In the past we have often wished that we possessed some agent which would improve nutrition, stimulate the nerve centres, and aid restoration of normal inspiration by rapid oxidation of the blood and the tissues, while conquering the inflammation by the hot-water bag.

We rejoice to say that such an agent has been found in the inhalation of pure oxygen properly diluted by combination with a gas of lighter specific gravity than oxygen. Pure oxygen when used alone is too dense in its specific gravity to be absorbed by the capillaries, being also too powerful an oxidizing agent, and very irritating to the mucous membranes, especially in sub-acute forms of inflammation.

The gas which has been found best suited to dilute the oxygen is nitrous monoxide, and the formula used by the London Oxygen Hospital is considered the best by all leading writers upon oxygen. It is pure oxygen, two parts; one part of nitrous monoxide, and a small equivalent of ozone added to keep the oxygen fresh. This employment of ozone does away with any objection which might be made to gas compressed in cylinders, as it prevents rapid deterioration.

We cannot speak too emphatically upon the proper formula and the quality of the gas, because only by strict attention to both can we ameliorate and subdue diseased conditions.

Oxygen as a therapeutic agent is but little understood by the medical profession; and it is a very serious error to suppose that the ordinary commercial oxygen manufactured by calcium-light makers is a proper agent to be employed for therapeutic purposes. It is completely saturated with chlorine and other deleterious gases, which, being exceedingly poisonous, are most injurious to the patient. Obtain, therefore, the very best quality. We obtain our gas from Dr. Walton's Laboratory in New York, where the London formula, or any other, may be obtained that in the judgment of the physician may seem best suited to the case. We believe that all prominent druggists in the United States have Walton's gas.

In regard to the inhalation of oxygen in pneumonia we recommend its administration in the early stages, every two or three hours. In pneumonia the nose cannot be held, and the gas inhaled through the mouth, therefore it should be inhaled through the mouth or nose in a perfectly natural manner, taking long and deep breaths for a period of thirty seconds; then wait one minute and apply for another thirty seconds, until this has been done three times. In the advanced

stage of pneumonia administer every half an hour or continuously in very severe cases, as in the case reported by Dr. A. N. Blodgett in the *Boston Medical and Surgical Journal* of November 20, 1890. He has minutely detailed the results in an admirable manner.

The bounding pulse of pneumonia, the tendency to delirium and meningitis, as well as the accompanying tendency to inflammatory exudation upon the surface of the pleura, the pericardium and the upper portion of the peritoneum, all denote a great dilatation of the arteries of the whole upper body, and evidence that the most effective treatment, is, as rapidly as possible to contract the arterioles in this region to their normal calibre, and renew to every tissue of the whole organism that necessary oxygen which is being withheld just so long as this widespread congestion is allowed to remain.

In chronic pneumonia, we believe that the use of the spinal hot-water bag may be made, by judicious application, a power to gradually overcome the diseased processes, especially if combined with the inhalation of oxygen properly prepared for therapeutic administration.

The offensive odor of the breath and of the sputa in chronic forms of pneumonia may be best overcome by the inhalation of oxygen, for it is perfectly antiseptic in its properties, as well as an agent which will improve the general nutrition.

In the year 1881, when practising in Boston, we were called to a young girl suffering from an attack of pneumonia of the lower lobe of the right lung, and well-marked pleurisy of the same region. The temperature was 104° F.; the patient showed typhoid symptoms; and unless speedy relief was obtained, only a very unfavorable prognosis could be given. The patient had been much overworked for some time before contracting the attack, and the second stage of the disease had already been reached before our arrival.

We at once applied the spinal hot-water bag, filled with water at 115° F., over the dorsal sympathetic ganglia. The relief to the dyspnea, pain, and a tendency to confusion of thought was almost immediate; and the patient fell asleep, waking in two hours covered by a profuse perspiration, and the temperature reduced three degrees. In twelve hours the temperature had fallen to the normal, the bag having been applied for one hour every three hours, except the first application, which was longer.

The bag was then continued three times a day for two days, when all recurrence of temperature rise having ceased, it was stopped, and only a double thickness of flannel placed over the region covered by the bag. This we advised the patient to wear for some weeks, in order to strengthen the weakened sympathetic ganglia. The patient was practically convalescent in twelve hours after treatment began, but the great trouble we had was in restoring the general strength; and we are now convinced that if we had possessed one or two cylinders of properly combined and prepared oxygen, and given it by inhalation, the patient would have much more rapidly recovered her vigor.

From a very instructive and interesting article published by Dr. J. N. DeHart in the *Maryland Medical Journal* of August 31, 1895, we cull the following remarks. The article is entitled, "The Therapeutic

Value of Oxygen in Pneumonia, Bronchitis, Anemia and Chronic Diseases." He says:

"In pneumonia it relieves the patient by overcoming the cyanosis, and furnishing a fresh supply of oxygen to the blood.

"In a case of double pneumonia, occurring in a woman thirty years of age, the gas was not prescribed until the fifth day, and the cyanosis was very marked.

"Temperature 106°, pulse 170, respiration 65. After the inhalation of five gallons of the gas, the patient was much relieved. The temperature was reduced to 104°, pulse 140, respiration to 45, and the countenance resumed its normal appearance. The inhalations were continued every half-hour for seven hours, and then once an hour for the following day; after that, resolution began in both lungs, and the gas was given every two hours for the following three days. It was given at frequent intervals for the following two weeks, until the patient was able to leave the bed."

He recommends the inhalation of oxygen combined with nitrous monoxide, and advises its use in the early stages as giving the best results; for, while many physicians have found much relief experienced in the later stages of the disease, the results then, although decidedly comforting and ameliorative, have not always been curative. He also says that a physician in Troy, N. Y., used the same combination of gases in treating thirty-five cases of pneumonia during the early stages of the disease, and that they all recovered. He also declares that it relieves promptly the most intense dyspnea, whatever its origin.

It appears to the writer, from his observation during the past sixteen years of the action of heat and cold over the spine (and their power in the former case to contract the arterioles, and in the latter to expand them and make more active the circulation and the general processes of nutrition), that the relief given by oxygen when inhaled in inflammations of the respiratory organs must be at least partly due to the fact, that by the stimulation induced in all the tissues of the body, and the generally bettered nutrition, the excess of the blood contained in the inflamed area must be withdrawn and the arterioles in the diseased tissues contracted, while the local excess of blood is carried off by the systemic arteries, the blood in which is now more completely oxygenated, to be distributed normally to all parts of the body and aid in strengthening the exhausted and previously insufficiently oxidized tissues.

This personal conviction is corroborated by the fact that only by the contraction of the arteries in the inflamed region, can the inflammatory process be subdued; therefore, when we find an agent lowering the temperature, reducing and calming the pulse, and diminishing the rapidity of the respiration, we know that there must be a reduction of the inflammation in the inflamed area, and therefore a contraction of the widely distended arterioles, in the region.

Heat applied between the shoulders, or over the dorsal sympathetic, with the prompt administration of oxygen properly combined and prepared for therapeutical purposes, will, especially in the early stages, we believe, quickly, rapidly and safely restore the diseased lung to its normal condition and the patient to health.

The administration of oxygen by means of a cylinder is very simple, as you have only to turn a stopcock off and on.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

JOHN DANE, M.D., SECRETARY.

REGULAR Meeting, Saturday evening, October 30, 1897, DR. FRANCIS H. BROWN presiding.

DR. RICHARD C. CABOT read a paper on

ALCOHOLIC STIMULATION IN CONTINUED FEVERS.¹

DR. JOHN L. HILDRETH described his

IMPRESSIONS OF THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

DR. E. G. CUTLER read a

RECORD OF TWO CASES OF BEGINNING PULMONARY TUBERCULOSIS TREATED WITH SUBCUTANEGUS INJECTIONS OF KOCH'S TUBERCULIN T. R.²

DR. CUTLER said: Until I saw the Koch Tuberculin T. R., which was produced by John T. Milliken & Co., of St. Louis, a firm of manufacturing chemists, and placed at my disposal by their agent in Boston, Mr. Humes Hall, I had some hesitancy in making use of the substance, because I had seen that in T. R. which came from abroad they had found tubercle bacilli which could be stained and had got some cocci in the culture. I had a bottle from this house given to me by Mr. Hall and gave it to Dr. Wright of the Bacteriological Laboratory of the Massachusetts General Hospital, and he obtained cultures of cocci. They were very small in number, and so after making a few experiments with it I decided to use the article. It is certainly a very active agent. Two cases which I report came into the hospital. They were having pulmonary hemorrhages. Tubercle bacilli were discovered in numbers in each case. The temperature ran tolerably high, it was about 102°. After watching the temperature a time and trying other modes of treatment, I commenced the use of tuberculin residue of Koch, and gave to begin with the official dose, one five hundredth of a milligramme. Koch says that the patient shall be given a dose so small that there shall be relatively little reaction from it. He says a rise in temperature of more than one-half a degree of the Centigrade scale shall not be allowed, and he orders the injection to be given every third day, that is, skip one day, and that the injections, doubled each time, shall average about fourteen in number. I followed out this procedure closely and the patients got along uninterruptedly well. One, I believe, had a temperature after the third or fourth injection of 100°, that is to say an increase of one degree over the temperature he had had. He felt, however, perfectly well. At the last injection of that same patient he had a chill and a considerable rise of temperature, but felt perfectly well. The cases were uneventful except that they got better. The tubercle bacilli, which were found abundantly in the first instance, got less and less frequent and abundant. It was harder to demonstrate them, and the patients progressively increased in weight. One of them I got a letter from after he left the hospital. He said he had increased his weight something like six pounds the first ten days of treatment, and after that he increased still more rapidly, until finally he

¹ See page 573 of the Journal.

² See page 571 of the Journal.

wrote me he had gained as much as twelve pounds. On the twenty-fifth of October I saw him. He was perfectly well, and I found no physical signs, no expectoration. He did not have time to let me examine him carefully, and so I tried to get some expectoration, and found nothing but saliva.

I have here the charts of the two patients. The first one came in with a pretty high temperature and after the injections it progressively got lower. He finally went out with a perfectly normal temperature after a period of twenty-eight days. The bottles of tuberculin substance contain each a cubic centimetre, representing twenty-five five-hundredths of a milligramme. You begin with one five-hundredth, and the second injection is two five-hundredths, the third four five-hundredths, etc., doubling each time until you get sixteen milligrammes, at which time usually the patient is so much better that he does not need any more injections. There are cases, however, which require more.

I have here a postal card I received from the second patient, who writes as follows: "I have gained six pounds in weight since leaving the hospital. I weighed myself the 12th of October, fifteen days after leaving, and in estimating the gain was careful to weigh and deduct all extra clothing. I am scarcely ever troubled by coughing and raise absolutely nothing. I feel strong and well in every way." I saw him the 28th of October, as stated before, and he had gained twelve pounds since the last record which he sent me. He looked perfectly well, had no cough and felt well. I could find no physical signs.

I would say that at the same time I used the Tuberculin T. R. on these two beginning cases of tuberculosis I used it also on three others pretty far advanced, and I found it had the same effect on them in some respects that it had on the early cases, namely, that the cough and the expectoration diminished, that the physical signs in the initial cases got better and finally disappeared, but in the severe cases the disease went on and the patient emaciated although the physical signs improved somewhat. The progress of the disease apparently was not at all affected by it in advanced stages, which was what Professor Koch had led us to expect from his assertions.

On motion of DR. C. P. PUTNAM, seconded by DR. P. C. KNAPP, the President, Vice-president, Secretary, and such other persons as the President should at his leisure think it proper to appoint, were constituted a Committee on

CHARITABLE AND REFORMATORY INSTITUTIONS.

DR. E. H. BRADFORD read a paper entitled

A STUDY IN HUMAN GAIT,

which he illustrated with lantern slides.

DR. CUTLER: I would like to say a word on Dr. Cabot's paper. I think Dr. Cabot has presented the subject admirably. It has been of late years my custom to give relatively little alcoholic stimulation in the class of cases he mentioned. The custom which I have adopted was to give, as Dr. Cabot has said, the alcoholic liquors to those to whom their use was habitual before and to those who were taking an insufficient amount of food. The amount of stimulants which I have used of late years has been extremely small in my hospital practice, and it is seldom I use it outside except in elderly individuals.

Recent Literature.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science. By leading authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Vol. XI, Diseases of the Nervous System. Vol. XII, Mental Diseases, Childhood and Old Age. New York: William Wood & Co. 1897.

The eleventh volume of this encyclopedia is devoted to Diseases of the Nervous System; a very important department of medicine, in which much work has been done and great advances have been made in recent years. The first half of the volume is devoted to the consideration of the Cerebro-Spinal and Sympathetic Nerves, by Dr. James Hendric Lloyd. The next article takes up the Trophoneuroses, excluding scleroderma, acromegaly, and adiposis dolorosa; this article is by Dr. Charles K. Mills. The three diseases excluded from the preceding are discussed in a separate article by Dr. F. X. Dercum. These three contributors are all of Philadelphia.

An article of 240 pages on Diseases of the Spinal Cord is from the pens of Drs. L. Bruns, of Hanover, and Dr. F. Windscheid, of Leipsic.

On *Tabes Dorsalis*, which we are accustomed to regard as a disease of the spinal cord, Dr. P. J. Möbius, of Leipsic, gives a contribution of nearly a hundred pages — no more than the importance of the subject demands.

The writer has been the reporter on *tabes* for *Schmidt's Jahrbücher der Gesamten Medicin* since 1879. In regard to syphilis as a cause, he goes, if anything, even farther than Erb, as appears from the following statements: "We know now that *tabes* is metasyphilis, that is, a sequel of syphilis. *Tabes* becomes more frequent in just the degree that syphilis extends. . . . Like *tabes*, general paralysis of the insane was late in being recognized, but becomes more frequent year by year. The two diseases, in my opinion, are essentially one — metasyphilis of the nervous system. . . . With our present knowledge it is proper to view syphilis as the *conditio sine qua non*, or as the primary cause in all cases of *tabes*."

The last article, on *Pain*, is written by Dr. Lightner Witmer, of Philadelphia.

Volume XII deals with Mental Diseases, Childhood and Old Age. Dr. Fielding Blandford, of London, contributes the most important article, of 250 pages, to this volume, on *Insanity*. Dr. Paul Sollier, of Paris, writes on *Idiocy*. Cesare Lombroso, of Turin, has a comparatively short article on *Criminal Anthropology*. Dr. J. Boy Teissier, in charge of the Hospice des Vieillards, at Marseilles, writes about *Old Age*. Dr. Jules Comby, of Paris, treats of the Diseases of Children, including infectious diseases and rachitis, in a final article of 300 pages. This makes rather a motley collection of subjects to be bound between the same covers, but the separate articles in themselves are good.

Had Dr. Möbius written the chapter on "General Paralysis of the Insane" in Dr. Blandford's article on *Insanity* the statements in regard to etiology would certainly have been very different from what they are, and the conclusions would likewise have been different. Discordant statements and conclusions are inseparable

from composite authorship, which merely means that doctors sometimes disagree. To the student this is perplexing; the practitioner should have learned to make allowances for the point of view.

Diseases of the Ear, Nose, and Throat and their Accessory Cavities. A Condensed Text-book. By SETH SCOTT BISHOP, M.D., LL.D., Professor in the Chicago Post-Graduate Medical School and Hospital; Surgeon to the Illinois Charitable Eye and Ear Infirmary. Chicago, New York, Philadelphia: The F. A. Davis Co.

This is a book of about five hundred pages for the use of medical students and general practitioners. It is a convenient size for reference; that is, it is more convenient than a larger size would be, and it includes the ear, and nose and throat in one volume. Text-books of this size may be very useful and contain all that many men need, but their compilation requires much more than knowledge of the subject or experience in practice. Some subjects are treated at a length out of all proportion to their relative importance. After nearly thirty pages on hay fever, largely devoted to the question of the influence of uric acid, we find the subject of nasal mucous polypus dismissed in twenty lines. This insertion of lengthy discussion of certain subjects is explained in the preface as an endeavor to fill gaps in collateral literature; but it entirely destroys the proper balance of an introductory text-book. The illustrations are largely from Politzer, Sajous, and a catalogue of instruments; with a few photographs of patients.

Teachers differ so much in the kind of text-book which they want for their students that each additional one finds its place.

Karezza: Ethics of Marriage. By ALICE B. STOCKHAM, M.D. Chicago: Alice B. Stockham & Co.

It is very difficult and dangerous to say much about this little work. The theme itself is old, difficult and dangerous; it is that old theme which we may indicate by borrowing a simile used by the authoress in which she speaks of the still waters in which one may row at ease securely without fear, unless one wishes, of being carried through the rapids over the fall—the fall being pregnancy. And the danger and the difficulty are, moreover, increased by her peculiar method of treatment, which is a combination of physiological reasoning with spiritual exhortation. The latter is luminous, but the former is not lucid. We imagine the course inculcated to be based on two relatively modern physiological doctrines: inhibition and internal secretion. We say *imagine*, for in this little work all details are carefully avoided. Things are dimly hinted at by metaphor and simile; but one is led to believe that plainer statements are to be found in other works by the same authoress or by other authors, whose titles, like that of the volume in hand, are, philologically at least, distasteful. We have not felt called upon to pursue the research into these other volumes, partly through fear that they, too, would equally fail to be explicit, partly for other reasons, and therefore must leave our readers in the same undesirable state of mind as that in which we find ourselves.

DR. GEORGE T. KEMP has been appointed to the chair of physiology in the University of Illinois.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 2, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

DEPARTMENT OF MENTAL DISEASES AT THE BOSTON DISPENSARY.

THE Boston Dispensary has lately enlarged its field of usefulness by the creation of a Department of Mental Diseases.

In a city the size of Boston there are naturally many cases of mental disease occurring among the poorer classes which escape recognition until so far advanced that hospital treatment becomes a necessity, or perhaps a tragedy takes place which leaves no longer room for doubt. It is a well-recognized fact that early treatment in mental diseases is as important as in any other class of diseases, and without doubt many hospital committals would be avoided if a diagnosis could be earlier arrived at.

The Boston Dispensary, with its immense number of patients seen both at the dispensary and in their homes, has within its reach a means of getting at the disease in its incipient stages, which should be of great utility if properly made use of. The new department will co-operate with the district physicians, and not only treat cases referred to it at the dispensary, but will also hold consultations with them in the patients' homes, and help clear up the diagnosis in obscure cases.

Patients with mental symptoms coming to any of the departments, as well as cases of alcoholism, epilepsy and so on, can be referred to this department.

It is believed that the department can be of considerable service to the dispensary physicians and the friends of patients by giving them information in regard to the necessary steps to commit patients to hospitals. Often suggestions to the latter may expedite committals and in some cases be the means of averting serious accidents. Only those who have had experience know how ignorant the poorer people are about insane hospitals, and how they delay and procrastinate when the time comes to take action.

It will be the earnest desire of the physicians of the new department to do what may be possible to bring

about a more clear and definite recognition of mental diseases before they become fully developed cases of insanity, and they will be glad to have any cases referred to them for observation and treatment.

Dr. Walter Channing has been appointed to take charge of the department, and he will have as an assistant Dr. Arthur C. Jelly. The department will open December 2d, and the hours will be from eleven to twelve, Mondays and Thursdays.

SEWER-GAS AND SEWER VENTILATION.

DR. WALFORD¹ addressed a circular to the Medical Officers of Health of English cities, and received replies from 45 upon the following points:

- (1) The method of ventilating sewers adopted.
- (2) Whether the method was approved by the Health Officer.
- (3) Whether complaints of nuisance from ventilators were numerous.
- (4) Whether there was reason to suppose that illness had been caused by the system adopted.

Out of the 45 towns, there were 18 in which the sewers were ventilated entirely by ventilators opening at the street level, and in eight of these the system was approved by the Health Officer. In seven there was a decided disapproval and in the remainder it was qualified.

In 24 towns ventilators at the street level were supplemented by pipes carried above the houses and in a few cases connected with factory chimneys. This system appears to be generally approved so far as the connection with chimneys is concerned.

Complaints of nuisance in cases of openings at the street level were "numerous" in 21 towns and "not numerous" in 16 towns. In some, complaints were confined to particular districts in hot weather.

In two towns sewers were ventilated by cast-iron pipes, 30 to 80 feet high and without street ventilators. Bristol was the only town in which the sewers were not ventilated at all, and this system was approved by the Health Officer and City Engineer who desired no change. There were only six affirmative replies to the question whether there was reason to attribute illness to the existing method of sewer ventilation. In 11 towns the Health Officer had some reason to suspect it. In 28 there was no reason to connect illness with the ventilation.

In summing up, Dr. Walford says: "After a careful consideration of the facts which I have been able to collect, I believe there is very little reliable evidence to show that the ordinary specific infectious diseases are caused by inhaling sewer-gas, and that usually where sewage is responsible for their causation, the mischief has arisen through swallowing either water or food which has become contaminated with sewage matters. . . . We find that whilst sewers,

and consequently sewer ventilators, have increased to a vast extent all over the country, these diseases have considerably diminished, and that this has been more particularly the case with typhoid fever, a disease which of all others has been most conclusively shown to be connected with poisoning by sewage matters."

MEDICAL NOTES.

NEW YORK.

THE BOARD OF HEALTH AND THE GENERAL PRACTITIONER. — At the November meeting of the Medical Society of the County of New York, at which the Committee on the Abuses of Medical Charity presented its supplementary report accompanied with the draft of a proposed new dispensary bill, the President-elect, Dr. Arthur M. Jacobus, delivered his inaugural address. In it he severely criticised some of the methods of the Board of Health, saying, in part: "As the spokesman for 2,500 reputable physicians of this city we condemn the free vaccination and the inspection and examination of school children for contagious diseases or defective vision, etc., regardless of the wealth of their parents or the rights of the family physician or other practitioner; we protest against the ever-increasing control, segregation and free treatment in public institutions and elsewhere of patients suffering from even ordinary infectious diseases which any physician of to-day is fully competent to quarantine and treat at home in most instances, and that, too, without the frequent officious visits and criticism of the department inspector or other employé." In the course of the address Dr. Jacobus recommended that the exact legal rights of the Health Board should be ascertained with a view to securing legislative relief of alleged abuses, and urged that the Society, in co-operation with other interested medical bodies, should use all possible influence to induce the Legislature to amend the law which excludes the members of the medical profession from the chief executive part of the Health Department. A committee was appointed to take into consideration the subjects referred to. The committee consisted of the following members: Drs. T. E. Satterthwaite, A. M. Hadden, A. Jacobi, H. G. Piffard and A. A. Smith. The Committee on Legislation was directed to attend the next session of the Board of Estimate to protest against the appropriation of public moneys for private charities.

A VERY LITTLE ONE. — There is at present in one of the incubators at the Lion Institute an infant (said to have been born at full term) which, on admission, weighed only 20¾ ounces. The matron in charge, who has had an immense experience with the mites of humanity at Paris, Lyons, Nice and other cities of France, states that the child is the smallest that she has ever met with. There are now at the Institute twelve incubator children, one of whom is the daughter of a prominent New York physician.

¹ Sewer Ventilation and its Bearings on Public Health, by Edward Walford, M.D., Cardiff, Wales, The Sanitary Record, July 30, 1897, p. 119.

SULPHUR-CHARGED GAS AT MOUNT VERNON.—The medical men of Mount Vernon, just beyond the northern limits of New York, and now a city of over twenty thousand inhabitants, had a very busy time of it on the night of November 19th, when the East Chester Gas Light Company pumped 270,000 cubic feet of sulphur-charged gas into the homes of the people. A very large number of persons were made ill by the poisonous gas, some of the cases being quite serious, but no loss of life resulted. The cause of the trouble was ascertained to be an accident in connection with the purifying process, by oxide of iron, at the gas works.

DEATH OF DR. JULIUS A. SKILTON.—Dr. Julius A. Skilton died suddenly at his home, in Brooklyn, on November 20th. He served with distinction as an army surgeon during the Civil War, and later acted as war correspondent of the *New York Herald* in Mexico. On one occasion he had a very narrow escape from death as a spy, but managed to reach the protection of a foreign vessel. He had much to do with the Emperor Maximilian, and after the latter's death exhumed the body and arranged for its transportation to Austria. After the cessation of hostilities he was medical officer of the escort which took President Juarez to Mexico and restored him to power. He was appointed Consul-General in the City of Mexico, by General Grant, and at the close of the latter's second presidential term engaged in mining and railroad enterprises in Mexico. He also made extensive archeological researches and discoveries, and his valuable collection is now in the museum of Yale University, of which he was a graduate.

Miscellany.

THE NEED OF MEDICAL EXAMINING BOARDS.

W. P. HAMAKER, M.D., of Meadville, Pa., a member of the Pennsylvania State Board of Medical Examiners, publishes in the *Pennsylvania Medical Journal* the following answers from the papers handed in at a recent examination by the board, as examples of the ignorance which it appears is not incompatible with the possession of the diploma of a medical school. All the authors of the following answers were the possessors of diplomas:

"Hydrogen gas is degenerated from the urea." "Cantharides is derived from the root of the plant." "Pix liquida is derived from the Pinus Somniferous group." "Cantharides is derived from the destructive distillation of the Spanish fly." "The malar bone articulates with the occipital bone." "Picrotoxin is an alkaloid of senna and rhubarb." "Sparteine and eserine are alkaloids of somnifer papaverum." One said that "Sparteine was derived from Sparta," and another said it "was derived from Spartus." Another said "that vinegar was an antidote for mineral acid poisons," and another stated that "an infusion of Spanish fly was one of the official preparations." Another gave us the information that "the uriniferous tubules secrete the seminal fluid." Another said that "belladonna looks up all of the secretions except the urine and feces." Another stated, without additional matter of any kind,

that "the differential diagnosis between epilepsy and hysteria is that in epilepsy they fall on the stove and burn themselves, and in hysteria they don't." Turning to obstetrics, one man, in rigid os, "would decapitate or perform craniotomy or he would put on the forceps and deliver at once." Another, in performing version, "would put his finger in the child's mouth and bring the chin under the os pubis, and hold his hand over the mouth to prevent the liquor amnii from choking it." Another stated "that the endocardium is a mucous membrane which weighs two ounces, and is separated from the pleura by the pericardium." Another stated "that the function of the optic nerve is to contract the pupil and move the eyeball." A new diagnostic symptom was offered by another man whose paper stated "that in cerebral hemorrhage the patient may vomit the cerebro-spinal fluid!"

THE ETIOLOGY OF DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA.

"ONE of the most frequent characteristics of Dupuytren's contraction is the bilateral symmetry of the lesions," writes Féré in the *Revue de Chirurgie* for October 10, 1897. This symmetry is in favor of a constitutional condition as the cause, and relegates traumatism and external agencies in general to second place in etiological importance. The additional fact of importance is that the contraction often coexists with other conditions which indicate various trophic troubles. Rheumatism and herpetism often figure among the hereditary or personal antecedents of sufferers from Dupuytren's contraction. More rarely the contraction is found in diabetics. A relation between it and the other trophic lesions in diabetes is possible, as shown by the case of Dreyfus-Brisac, in which it coexisted with *mal perforans* in a diabetic. It is often found associated with gouty tophi, or other trophic lesions which are observed in the gouty.

Numerous authors, notably Kirby, Paget and Tuffier, have described in gouty and arthritic patients an induration of the fibrous tissue of the penis, and Verneuil has observed this in diabetics. This induration of the penis has been noted several times in sufferers from Dupuytren's contraction (Cameron, Poisier, Castillers, Delaborde), and has been well established by the observations of Jonathan Hutchinson, who has carefully described this induration of the dorsum of the penis, causing a curvature of the organ with a concavity downward, which makes erection painful and prevents coitus. Féré has found these conditions coexisting in one of the cases described in his article.

Dupuytren's contraction is also frequently found in sufferers from diseases of the nervous system; it has been noted in sufferers from locomotor ataxia and general paralysis. Féré has seen it in an hysterical patient, and reports in his paper two cases in epileptics.

As regard predisposing causes, traumatism probably is of considerable importance. Féré reports the case of a man coming of a gouty family who was attacked with acute contraction of the palmar fascia of the right hand following repeated pressure, and in whom a similar contraction appeared in the left hand, apparently without provocation. The predisposing effect of traumatism is apparently supported by the situation at which the disease begins. The contraction usually appears first at, and frequently remains limited to, the base of the ring and little fingers, a part which is much exposed to traumatism in laboring men.

Involvement of the base of the middle finger is not uncommon; but if one may judge by the reported cases, the base of the index finger is rarely affected, and the thumb very rarely indeed. Even in cases where the disease has extended to the radial region of the palm, the ulnar region is seen to have been chiefly and primarily involved; and this fact is also true of the rare cases in which the thumb is invaded.

ATTACK OF WITCH DOCTORS ON MEDICAL MISSIONARIES IN RHODESIA.

"THE *Edinburgh Evening Despatch* of Nov. 17th, gives an account of the attack of native witch doctors on Dr. and Mrs. Owen, of Zimunya, Rhodesia, where they had established themselves for medical missionary purposes.

"Zimunya is a lonely station, consisting of three huts and a tent on the summit of a high mountain in Mashonaland, about twenty-five miles from Umtali. Staying with them was a friend, the Rev. L. M. Caulfield, of Umtali, who fortunately had brought with him his collie dog. About four in the morning they were all roused by the barking of the dog, only to find the witch doctors making a fierce attack on the mission-house. Dr. Owen fired at the miscreants, but they made a hasty retreat, and unfortunately escaped. It was then found that the dog had been killed by the blow of an assegai. The Rev. Mr. Caulfield attributes the attack to the jealousy of the native witch doctors, who for many generations have attended the sick, and, it would seem, have been well paid for their services—sometimes, it is said, to the equivalent of £4 or £5 a case. They found their occupation gone and their reputation eclipsed by the enlightened treatment of Dr. Owen, for which no charge was made. It is inevitable that in Africa, as elsewhere, the witch doctor must be superseded by the educated physician, and we congratulate Dr. and Mrs. Owen on the happy ending of what might have been a serious disaster. We are not entirely without sympathy for the superseded local practitioners. They upheld the dignity of the art in one respect—they charged for their services, and it is open to them to say that their successful competitor owed his success rather to the fact that his advice was gratuitous while theirs was not. The missionary uses of medicine are most legitimate and beneficent, and in the case of the poor they must be applied without money and without price, but the more free from pauperizing abuse it is the better. If the natives can pay, as apparently was the case with many of the people there, they should be required to do so. In introducing the virtues of religion into barbarous countries we must try not to introduce its vices."—*The Lancet*.

THERAPEUTIC NOTES.

THE PREVENTION OF IODISM IN THE USE OF POTASSIUM IODIDE. — Spencer (*Journal de Médecine de Paris*) is credited with the following formula:

R Potass. iodidi	parts xxx.
Ammon. ferrocitratis	parts iv.
Tinct. nucis vomice	parts viij.
Aq. distillatæ	parts xxx.
Tinct. cinchonæ	q. s. ad. parts cxx.

M. Sig. A teaspoonful in half a glass of water, to be taken after each meal. The tincture of nux vomica and the ammonio-citrate of iron are said to check the tendency to coryza and at the same time to act as tonics.

QUININE MIXTURE. — The following (*Journal de Médecine de Paris*), is advantageous in irritable stomach when quinine is to be given:

R Quinine sulphâ	12 (gr. ii.)
Ac. citrici	36 (gr. vi.)
Syr. simplici	035 (gr. ss.)
Syr. aurantii flor.	035 (gr. ss.)

This is to be placed in a wineglass containing bicarbonate of sodium (from three to five grains) in saturated solution and drunk during effervescence.

AN APPLICATION FOR URTICARIA. — Gaucher (cited in the *Gazette Hebdomadaire de Médecine et de Chirurgie* for July) recommends this:

R Mentholis	1 part.
Chloroformi	} aa 3 parts.
Etheris	
Spts. camphorin	

M. To be used as a spray or as a lotion. The part should then be dusted with powdered starch or zinc oxide.

ACUTE LOCALIZED PROSTATITIS (*Journal des Praticiens*):

R Iodoformi	} aa 03 (gr. ss.)
Ext. hyoseyami	
Olei theobromati	
	3 (gr. xlv.)

M. Sig. Use as a suppository.

COMPOUND TINCTURE FOR THE TREATMENT OF GOUT (Dr. V. Gayle, *Buffalo Medical and Surgical Journal*):

R Tinct. stramonii	4 (3 i.)
Tinct. colchici	6 (3 iss.)
Tinct. guaiaci	60 (3 ii.)

M. Three teaspoonfuls daily in milk.

TREATMENT OF SOFT CHANCER BY SALICYLIC ACID OINTMENT (*Buffalo Medical and Surgical Journal*). — A Hungarian practitioner, Dr. E. Szánto, has come to the conclusion that, of all the means employed against soft chancres, salicylic acid is the best. He uses it in the form of an ointment as follows:

R Ac. salicylic	1 (gr. xv.)
Vaselin	30 (3 i.)
Tinct. benzoin	2 (3 ss.)

For external use.

PILLS FOR CONSTIPATION IN CHILDREN. — Pruyss (*Journal de Médecine de Paris*) is credited with the following:

R Extract of cascara sagrada	grains xxx.
Extract of frangula	grains xv.
Powdered aloes	grains lx.
Powdered gentian	each
Medicinal soap, q. s.	

M. Divide into eighty pills.

Sig. From one to four pills to be taken at bedtime.

Correspondence.

A DEPARTMENT OF PUBLIC HEALTH AND THE AMERICAN MEDICAL ASSOCIATION.

MILWAUKEE, November 27, 1897.

MR. EDITOR:—In a communication published in the November 25th issue of the JOURNAL, signed by H. W. Austin, M.D., there appears the following:

"In fact, the American Medical Association the year previous at the Atlanta meeting in adopting a report of its committee on a Department of Public Health, which report recommended that the committee be authorized to draft a bill which should be in accord with the recommendations of their report, expressed views which are entirely opposite to those embraced in the report of the committee at the last meeting recommending the proposed bill for a Department of Public Health."

As I had to do with the framing of each of these reports, and deeming it of considerable importance that the medical

profession should know the exact truth in regard to this matter, I respectfully submit herewith the two reports in their order:

REPORT OF THE COMMITTEE ON DEPARTMENT OF PUBLIC HEALTH AT ATLANTA.

Your Committee was appointed in 1891, with the object in view of securing the passage of a law creating a National Department of Public Health, with a Secretary of Public Health at the head of it, with a seat in the Cabinet of the President of the United States. The bill which was prepared for presentation to Congress was extremely crude and indefinite in its provisions, and gave this proposed high official very little important work to do. It was, indeed, found to be so defective, that last year the effort to have it enacted into a law was abandoned.

In the meantime the Marine-Hospital Service, which in 1890 had already been invested with some important health functions, was by the act of 1893 converted into a National Health Department with very large and far-reaching powers and abundant means. It is not called a Department of Public Health but it is a Department of Public Health in fact. Since 1893 until the effort was abandoned last year your Committee has been engaged in the hopeless and unwise enterprise of endeavoring to induce Congress to establish another Department of Public Health — a very weak and inconsiderable department by the side of a very powerful department. Such an effort could not succeed. Such an effort did not deserve to succeed.

It seems to us to be a fundamental proposition that we shall have but one National Department of Public Health. This being conceded, one of three courses remains open to us:

(1) We may devise and advocate a plan to deprive the Marine-Hospital Service of its public-health functions, and for the establishment of an entirely new department; or

(2) We may accept the Marine-Hospital Service just as it stands, as a department sufficient for our present use; or

(3) We may endeavor to improve the Marine-Hospital Service and make it a more satisfactory health department than it now is.

It would seem that this last method promises to be the most fruitful of beneficent results, and the question then arises as to the modifications that may be wisely made in the existing law.

In arranging any scheme of national public health supervision it would seem advisable that nothing should be done to discredit and weaken the various State boards of health, but that, contrariwise, the effort should be to strengthen the State organizations and to foster and facilitate their further evolution. If this principle is conceded, it is at once made evident that the National Department of Public Health should act in and through the State boards of health, in co-operation and harmony with them, and not outside of them and independent of them. If the National Department acts within the States, independently of the State boards, and assumes the work that ought to devolve upon the State boards, then the State boards become comparatively useless institutions, and will fall into disfavor. Some of the State boards are still weak institutions, and any rivalry between them and the National Department in State work would doom them to speedy destruction. In this direction it would seem that additional legislation is needed, and the simplest plan to reach the desired reconciliation would embrace two provisions:

(1) That the National Department should act with the States by and through and in co-operation with the State boards.

(2) That the head of the National Department should call, annually, to meet in the city of Washington, an advisory council to be composed of one representative from every State board of health. This would bring about mutual understanding and co-operation and reciprocity of action, and would virtually constitute a great central school of public hygiene.

Such a scheme as this would probably command the approval and support of the National Conference of State Boards of Health, which Conference is quite as deeply interested in movements of this character as is the American Medical Association.

As the conclusion of the whole argument, we recommend that we be authorized to draw up a new bill along the lines we have indicated, and that we be authorized to invite the co-operation of the Conference of State Boards of Health and of the American Public Health Association in our endeavor to have the proposed bill enacted into a law.

All of which is respectfully submitted,
JEROME COCHRAN, M.D., *Chairman of Committee.*

It was moved that the report of the Committee be accepted, the plan outlined adopted, the Committee continued and enlarged by the appointment of a member from each State.

REPORT OF THE SPECIAL COMMITTEE ON THE DEPARTMENT OF PUBLIC HEALTH, PHILADELPHIA.

At the last meeting of the Association, held at Atlanta, Ga., your Committee on Department of Public Health, which was

appointed in 1891, with the object in view of securing the passage of an Act of Congress creating a National Department of Public Health, with a Secretary of Public Health in the Cabinet of the President of the United States, made a report of progress through its Chairman, the late and lamented Dr. Jerome Cochran. That report suggested that it was impossible to attempt to secure the passage of an act creating a cabinet officer, and recommended the drafting of a bill in which the powers of the Marine-Hospital Service, which was already a department of public health with important public-health functions under the existing laws, be enlarged, and that such a department should be so created as to require co-operation with the various State and Territorial Boards of Health; that report was accepted and its recommendations adopted, and in addition the Chairman was authorized to add to the Committee already appointed an additional member from each State and Territory.

Your Chairman was appointed by the President of the Association to succeed the late Dr. Jerome Cochran in October last, and in looking over the field found that it was impossible to get either the Fifty-Fourth Congress, or the special session thereof, to take any action on such a measure, so he has appointed the additional members of the Committee, a list of which may be found published in the JOURNAL for January 16, 1897, and which is appended herewith, and has drafted a bill which is presented herewith.

Your Committee recommends the continuance of the Committee with power to have the aforesaid named bill amended to meet requirements but not to change the general purposes thereof, and to introduce the same into Congress at its discretion, and that the members of the Association be requested to do all in their power for its passage.

Respectfully submitted,

U. O. B. WINGATE, *Chairman*, LISTON H. MONTGOMERY,
WILLIAM BAILEY, CHARLES DENISON,
H. L. E. JOHNSON, W. B. ATKINSON.

To this was appended the names of the members appointed representing each State and Territory, and a full text of the bill. The bill, briefly stated, provides for the appointment of a Commissioner of Health by the President, subject to confirmation by the Senate; also an Assistant Commissioner of Public Health, and that the Commissioners of Public Health shall call an advisory council to meet twice a year in Washington, consisting of one representative from each State and Territorial Board of Health, and also one officer learned in the law, detailed by the Attorney-General of the United States from the Department of Justice. It provides that the Department of Public Health shall be under the control and management of the Commissioner of Public Health. It also provides that there shall be in said department a bureau to be known as "The Bureau of the Marine-Hospital Service," which shall be under the exclusive control of the Commissioner of Public Health, and all laws governing the appointment to official positions in said Marine-Hospital Service and to promotions in said service shall continue in full effect, and all funds now or hereafter appropriated for the Marine-Hospital Service by Congress shall continue to be disbursed under the supervision of the Commissioner of Public Health by the direction of the Secretary of the Treasury, until otherwise provided by law, it being the intent and purpose of this act to continue the Marine-Hospital Service under its present management, and to confer all duties relating to quarantine and the public health upon the department hereby created.

Very respectfully yours,
U. O. B. WINGATE, M.D.

BIBLIOGRAPHY OF ARTICLES BY WM. WARREN GREENE, M.D.

150 LOWRY ARCADE, ST. PAUL, MINN.
November 26, 1897.

MR. EDITOR: — I am making an effort to obtain a complete list of the articles published by my father, the late Wm. Warren Greene, of Portland. The references are scattered and difficult to obtain, and I would ask that any of his old students or professional friends, who have reprints or references to articles, will kindly advise me concerning them, thereby conferring a favor which will be greatly appreciated.

Very truly yours,
CHAS. LYMAN GREENE, M.D.

METEOROLOGICAL RECORD

For the week ending November 20th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,368; under five years of age 685; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 263; acute lung diseases 311; consumption 280; diphtheria and croup 112; typhoid fever 45; diarrheal diseases 45; measles 20; scarlet fever 19; cerebro spinal meningitis 8; whooping-cough 7; malarial fevers 5.

From measles New York 16, Pittsburg 4. From scarlet fever New York 10, Philadelphia 3, Brooklyn, Cleveland, Pittsburg, Charleston, Cambridge and Everett 1 each. From cerebro-spinal meningitis New York and Boston 3 each; Cambridge and Quincy 1 each. From whooping-cough New York and Brooklyn 2 each, Philadelphia, Boston and Pittsburg 1 each. From malarial fever Nashville 3, Brooklyn 3.

In the thirty-three greater towns of England and Wales, with

an estimated population of 10,992,524, for the week ending November 13th, the death-rate was 19.0. Deaths reported 4,009; measles 157, diphtheria 70, diarrhea 68, whooping-cough 61, fever 59, scarlet fever 46.

The death-rates ranged from 10.7 in Cardiff to 27.1 in Bolton; Birmingham 21.7, Brighton 14.2, Croydon 14.6, Gateshead 13.9, Hull 15.3, Leeds 19.2, Leicester 16.1, Liverpool 23.1, London 19.4, Manchester 18.9, Newcastle-on-Tyne 17.0, Nottingham 16.1, Salford 22.3, Sheffield 24.7, Sunderland 18.3.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 20, 1897, TO NOVEMBER 26, 1897.

CAPTAIN ISAAC P. WARE, assistant surgeon, is relieved from duty at Fort Grant, Arizona, to take effect upon the expiration of his present leave of absence, and ordered to Benicia Barracks, Cal., for duty.

CAPTAIN MERRITTE W. IRELAND, assistant surgeon, is relieved from duty at Benicia Barracks, Cal., to take effect upon the arrival at that post of CAPTAIN WARE, and ordered to the Presidio of San Francisco, Cal., for duty.

PROMOTION.

MAJOR PETER J. A. CLEARY, surgeon, to be deputy surgeon-general with rank of Lieutenant-Colonel, November 15, 1897, vice Waters, retired.

CAPTAIN CHARLES RICHARD, assistant surgeon, to be surgeon, with the rank of Major, November 15, 1897.

FIRST-LIEUTENANT PAUL F. STRAUB, assistant surgeon, to be assistant surgeon, with the rank of Captain, November 4, 1897, after five years' service.

RETIREMENT.

LIEUTENANT-COLONEL WILLIAM E. WATERS, deputy surgeon-general, November 15, 1897.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING NOVEMBER 25, 1897.

H. W. SAWTELLE, surgeon. To proceed to Memphis, Tenn., and assume temporary command of service. November 23, 1897.

C. E. BANKS, surgeon. To inspect Service at Buffalo, N. Y., and Philadelphia, Pa. November 22, 1897.

A. H. GLENNAN, passed assistant surgeon. To rejoin station at St. Louis, Mo., via Washington, D. C. November 19, 1897.

G. M. MAGRUDER, passed assistant surgeon. Granted leave of absence for ten days on account of sickness. November 20, 1897.

J. O. COBB, passed assistant surgeon. To proceed to Delaware Breakwater Quarantine Station for temporary duty, and then to rejoin station. November 19, 1897.

C. P. WERTENBAKER, passed assistant surgeon. Granted leave of absence for seven days on account of sickness. November 23, 1897.

BOOKS AND PAMPHLETS RECEIVED.

Headaches from Nasal Causes. By Sargent F. Snow, M.D., Syracuse, N. Y. Reprint. 1897.

Ein Fall von Adeo-Carcinoma der Nase. Sonderabdruck aus dem Archiv für Laryngologie. Von F. E. Hopkins, M.D.

Operative Surgery at the Philadelphia Polyclinic, from May 1, 1896, to September 1, 1897. By Francis T. Stewart, M.D. Reprint. 1897.

Experimental Basis of the Dietetic and Medicinal Treatment of Hyper-Acidity and Gastritis. By John C. Hemmeter, M.B., M.D., Ph.D. Reprint. 1897.

Proceedings of the Seventh Annual Meeting of the Association of Military Surgeons of the United States. Held at Columbus, O., May 25, 26 and 27, 1897. Edited by James E. Pilcher, M.D., Captain in the Medical Department of the United States Army; Secretary and Editor of the Association. Columbus, O. 1897.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections. In photo-lithochromes from Models in the Museum of the Saint Louis Hospital, Paris, with explanatory wood-cuts and text. By Ernest Besnier, A. Fournier, Tenneson, Hallopeau, Du Cartel, Physicians to the Saint Louis Hospital, with the co-operation of Henri Feulard, Secretary, L. Jaquet. Edited and annotated by J. J. Pringle, M.B., F.R.C.P., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Part XII. London: The Rebman Publishing Co. Philadelphia: W. B. Saunders. 1897.

Lecture.

CHARACTERISTICS OF INSANITY.¹

BY WALTER CHANNING, M.D., BROOKLINE, MASS.

THE striking thing you will notice in your intercourse with insane persons is that you can never get on a common footing with them. There is always some intangible, indefinite, undefinable obstacle to mutual comprehension, which prevents the usual good understanding we expect to have with every one. Often there is the greatest willingness on the insane person's part to appreciate what you say, and to co-operate in what you wish him to do; and very often he is himself perfectly satisfied that he is wholly one with you. But all the time you will have the vague consciousness there is a third party to the transaction. You do not alone have his ear—you are addressing him, *plus* some other side of his personality, and he unconsciously is giving a qualified assent to your arguments. Your attitude toward him is somewhat similar to that toward a child, in which case you do not expect to be fully understood, and you intentionally leave a margin in your mind for his inability to grasp what you say. You explain this simply enough by the fact of the child's imperfect development; his mind is not matured. The explanation is in keeping with the nature of things and is sufficient.

With the adult the case is different. He may be intellectually your equal, or superior, yet there is just this degree of what the French call "disharmonie," which parts you mentally, and no explanation can suffice except that you or he are mentally of unsound or disordered mind. In these remarks I am assuming that the person is insane, but to a degree not particularly noticeable, and requiring some skill possibly to find out just what the form of trouble may be. I am assuming also that he is not a person dull and stupid mentally, who would naturally find it hard to make out what you meant, but a person of average intelligence.

I am often struck in my interviews with insane persons with their lack of congenialness. Even without speech, there is a lack of attraction, even a repulsion of a very subtle kind sometimes. You are asked to give nothing; you are not needed, often not wanted in that world, entrance to which is denied you. Even if you may be called on and even prayed for to help, as I sometimes have been, you will still be aware of this negative attraction, which holds you at arm's length.

Alienists very often speak of this *lack of responsiveness* in their patients, and I wish to direct your attention to it, for it is a marked characteristic of the insane. We see people often enough who do not respond to what we may say, or do, but they have their reasons, which will be found, on the whole, consistent under the circumstances. With the insane, on the other hand, it is practically the opposite; their reasons are not, on the whole, consistent.

This brings me to another point, which is, that *we judge the insane very much by what they do*; by their actions, or conduct. You may often find no trace of mental impairment *in words*, when you would clearly do so *in acts*. Do not expect, as many do, that the

insane will give utterance to strange, grotesque, fantastic ideas, which will stamp them at once as insane. Many times a very insane man will talk for a considerable period and give no sign of his disease. You may not on the surface get a complete clinical picture, but that is because you cannot see at one glance the whole of the human mind, not that the elements of the disease do not exist. I shall later tell you of cases of "partial insanity," where the mind *appears* touched only at one point, but that is because it is at that particular point only, at the given time, that the disease has broken through the crust which hides the working of the man's mind, and reveals itself to our gaze, which, in looking into the vast mysteries of human intelligence, is at best dull and stupid.

Observe then the acts of the supposed insane man. See if they are rational acts, in accord with what you would expect a man to do if placed as this man is. Inform yourself most carefully of his habitual methods of action; study into his environment. In well-marked cases the man is so changed that he is entirely unlike himself in what he does; in the more obscure cases it will usually be found that his conduct is inconsistent with what it always has been before, and with what the circumstances naturally demand it should be.

This, then, is the point which I wish to make, to return to more fully, if time allows in subsequent lectures, that a characteristic of mental disease is *inconsistency*. Where before was a man who could be relied on to act in a certain definite way, you now have a man who may, or may not, do what he did before. His present conduct is inconsistent with his past conduct; his opinions, his beliefs, his affections all are tinged with some hidden, new influence, which alters him, and shows how imperceptibly yet radically a man's whole nature may be overturned, and made inconsistent with itself, by the insidious, and often slow, growth of the morbid mental process.

Lack of adaptability is another characteristic. In the social life of the community each individual must to some degree adapt himself to others. To succeed he must have a definite end and aim at which he can only arrive by placing himself at the service of others and resolutely adapting himself to the requirements of the situation in which he is placed, and so through life he is always disciplining himself to meet the needs of the community, and the better he knows how to do it the more successful he will be. This particular quality is almost wholly wanting in the insane. The more developed the disease, the more the tendency to individualize dominates them. It is well enough for a man who has talent in one direction to individualize, or more correctly specialize, his work; but this means that he is directing his individual efforts to accomplishing something of an objective nature, and he is really adapting himself all the time to his work. The insane man, on the contrary, expects other things to bend to him. He is the centre of things. In as far as the others come to him he may be able to accept what they thrust on him, but he has no power to meet them half-way. All his efforts are for himself; he lives and moves and has his being in a kingdom bounded by the four walls of his own personality.

With this lack of adaptability goes the *lack of power to combine with others*. In rare cases, a few of the criminally insane have been known to combine to-

¹ A lecture delivered to the students of the Tufts College Medical School.

gether to plan an escape, but, as a rule, if you visit the wards of an insane hospital, you will be struck by the separate lives the patients lead. They often work together, walk together and talk together in small, or large numbers, because they are easily trained and disciplined, but each patient in whom the disease is well developed, unless convalescence has set in, is a kingdom, and a law to himself. He need not go to any one else for guidance, help or sympathy, because it all comes from within. Not that he consciously says this to himself, or realizes it; it is to the onlooker that it is apparent. It can be easily seen that this lack of power to combine, to enter into mutual arrangements for the common good, is a serious weakness in a community which is ever forming societies, or coteries for such a purpose. It may entirely prevent any success in a business way, or interfere, jeopardize or destroy the harmony of a family circle.

Change in the affections is an almost constant accompaniment of mental disease. I will not say that it is invariable, but it is to be regarded as a characteristic symptom. In conditions of depression, the insane man often thinks that he has ruined his family. Therefore he feels himself unworthy of their love, and for the time being believes he has lost it, and acts accordingly. In conditions of exaltation, there is indifference or positive dislike, or exaggeration of feeling. It depends on the degree of intensity of the disease. Where ideas of persecution are dominant, the affections may be entirely alienated. In conditions of depression it should have been further said that the expression of feeling is in abeyance, even if ideas of wickedness or unworthiness are not dominant in the mind. In mixed forms of mental disease there is every shade in the expression of the affections, but rarely if ever are they wholly normal. There is a lack of reciprocalness of feeling. However much affection may be lavished on the insane man, he fails to appreciate it at its true value, and returns little, or nothing. He cannot be expected to give what is temporarily in abeyance or permanently lost.

Loss of the sense of relation of things is another characteristic of the insane. The ordinary affairs of life, the important questions that may arise from time to time may make little or no impression on their minds; or if they do make an impression, it is an unnatural or perverted one, and in no way what might be expected. There seems to be no consciousness of what these things mean. In a case of religious delusional melancholia, the patient, a most affectionate and religious man, had lost his wife and daughter within a few days of each other. Though he was devotedly attached to them, and externally apprehended every element of his loss, yet in consequence of his disease he had not a feeling of sorrow, and while detailing to me the circumstances of their deaths, played solitaire unremittingly on the side of his bed! Here was not only a change in the affections but also an indifference to the proper relation of things.

While so little consequence may be attached to the important matters, *details are exaggerated* to almost any extent. Gestures, motions, words, looks may be freighted with a portentous significance. Articles of clothing, food, bits of paper, etc., all possess a new interest and value. The mind is so occupied with these material details that no time is left for more important ones. The consequence of this preoccupation is a gradual loss of grasp on things as wholes, and they

lose their normal appearance of totality and unity. The sense of relation to external objects thus becomes blurred and confused, and no longer possesses its former power of restraining, modifying and controlling the acts of the individual.

With this particular defect goes a *loss of the power of comparison*, a most important attribute of the mind, for when we cannot compare we lose the power of choice, and when that goes we may be morally unable to distinguish right from wrong.

A *loss of initiative power* naturally is common among the insane. Taking no longer a rational interest in their affairs, unable to adjust or adapt themselves to their work or social obligations, without the stimulus of love and affection for their families, unable to perceive wherein they are deficient because their power of comparison is gone, it is not remarkable that they feel no incentive or call to perform the duties which once seemed a matter of necessity as well as of pleasure.

There are other characteristics of mental disease which will be mentioned frequently in succeeding lectures, two of these being *loss of inhibitory power* or *disordered and weakened will power* and *diminished power of attention*, which I will briefly refer to here as being found in every well-developed case, as necessary elemental symptoms. No man wishes to lose his reason, and while he can consciously control his mental processes he will persistently strive to do so. The man of strong inhibitory force will by will power pass through strains, mental, moral and physical, which wreck the man deficient in such force. From physical causes the strong break down and their natural power of inhibition is weakened; but, other things being equal, the weaker man goes to the wall first. It is, of course, true, that men can be found, in all classes, of weak wills; and it is also true that many of the insane are extremely self-willed without there being perhaps perversion of will-power, or weakness in the ordinary sense. But there is markedly a loss of inhibitory control over the mental processes. The discriminative faculty of will (if we choose to use this expression) which checks aberrant mental action while it gives free play to what is natural, is in abeyance, or slumbers, or is stifled at its post.

Inhibition acts on the cerebral processes (thereby, of course, including both so-called mental and so-called nervous processes, which, as far as we know, are only different phases of one continuous process) somewhat after the manner of the operator in the signal tower of a railroad. Regularly the trains come and go, now on this track, then on that; one may be retarded or another hastened, but always there is regularity and continuity in the movements of the trains. As long as the operator remains at his post, unless some break occurs in the apparatus, no accident can happen, for his hand is on the lever which controls with absolute certainty every operation of every train. But once let him leave his post, and trust the trains to manage for themselves, and confusion and blocking of the whole road will result. Trains will occupy the wrong tracks, some may collide with each other; others may be thrown off the track. Where before we had system and regularity in moving trains, we shall now have fitful, spasmodic attempts to do the same, and before the operator again returns the whole road may be blocked.

So it is with the function of inhibition. When working normally, every cerebral process flows along

smoothly and continuously to a successful and immediate issue. Weakened or suspended, these processes become inchoate, vague, uncertain, paralyzed.

The other characteristic mentioned was the *loss of the power of attention*. We may say that attention means the power to consciously concentrate thought and project it continuously in one direction. Of all mental faculties this must be regarded as the highest. There are many degrees, however, of attention. The child will concentrate his mind on what he is interested in intensely for short periods to the exclusion of other subjects. But this is not wholly conscious thought, but largely instinctive, arising out of sudden overpowering interest and curiosity. To arrive at the point of higher development of attention requires training and self-discipline. The highest attention means that the mind can turn to the objective consideration of subjects. Emerson says that "A man is intellectual in proportion as he can make an object of every sensation, perception and intuition, so long as he has no engagement in any thought or feeling which can hinder him from looking at it as somewhat foreign."² In other words, man is intellectual in proportion to the power he possesses of directing his attention objectively to subjects.

Now we usually find intellectual impairment in the insane. Exceptionally there are insane persons in whom there is what seems enhanced intellectual brilliancy; but even in these cases all the elemental qualities of the finest intellect are generally not present and there is apt to be a lack of perfect equilibrium. Granting that there may be exceptions, the rule holds good that intellectual force and power are both weakened in mental diseases. If the man of intellect deals with subjects objectively, the converse is true of the insane man; he deals with objects subjectively. In the first case the man consciously puts his *ego* to one side; in the second case the man unconsciously puts everything but his *ego* to one side. One dominates the *ego*; the other is dominated by the *ego*.

We often speak of an insane man as "concentrating his attention on himself." This is, strictly speaking, an incorrect use of terms. In such a case the faculty of attention is so weakened that it cannot be exercised except negatively. The man's thoughts are concentrated on himself because he cannot make use of the modicum of attention he may have possessed. His mind feeds on itself because it cannot attend to anything else; it cannot "detach" itself.

We now come to more classical characteristics of mental disease—symptoms, I suppose I should call them—which, no doubt, are somewhat familiar to you all. I allude to delusions, hallucinations and illusions. Whenever one of these can be clearly and definitely enough diagnosed, so that there is no question of its existence, there is no reasonable doubt that we are dealing with a case of mental disease. On the other hand, there are many cases of undoubted insanity in which neither can be clearly determined, and some in which neither clearly exist.

Delusion is usually defined primarily as a "false belief," and I advise you to bear these two words in mind for future use, when you may find it difficult to recall quite what a delusion was said to be. It is a false belief contrary to the individual's past experience, inconsistent with his former thoughts and feelings, the result of disordered brain action.

Clouston says:³ "An insane delusion is a belief in something that would be incredible to sane people of the same class, education or race as the person who expresses it. This resulting from diseased working of the brain convolutions."

Kirchhoff, a German writer, calls delusions "false judgments." "They are due to the uncritical acceptance of the combination of ideas which occupy the foreground, and this depends on some morbid condition of the brain."⁴

Régis, a French writer, says: "Delusive conceptions are not only difficult to define because they are far from being always absurd in themselves, but also because it is not always easy to distinguish them from error. The difference does not consist, as has been claimed, in that the delusive idea is not changed in spite of the accumulation of the most absolute proofs of its falsity."⁵

Dr. Landon Carter Gray, of this country, states that a delusion is a false belief. Then he says it is sometimes stated that a false belief of the insane differs from a false belief of the sane, because the former is fixed and not amenable to reason; but this is a mistake, because the former is not always fixed and unamenable, while the latter sometimes is. "The only definition of an insane delusion," he says, "is that it is a false belief occurring in an insane person. Whether or not a person is insane is a question of diagnosis."⁶

The view of Dr. Gray, I have never known before adopted, and I must regard it as rather dangerous for a student who is trying to find solid ground to stand upon. Of course, we all must agree that a delusion of the kind we are discussing, which is the delusion of an insane man, must be a false belief occurring in an insane person; that goes without saying, but the last part of Dr. Gray's sentence leads one to infer that it is not a most necessary and often vital factor in diagnosis, which can be made independently. Do not accept that position for a moment, for it is untenable. If there is one diagnostic mark of any disease, it is that of delusion in mental disease. With that well made out, there is some assurance that you are correct, without it there is a very good chance you have not gone to the bottom of the case. Dr. Gray's assertion is like saying: "The only definition of the lesion of diphtheria is that it is the Klebs-Löffler bacillus recurring in a diphtheritic patient, but whether or not a person has diphtheria is a question of diagnosis."

You will observe, in Clouston's definition, that care is taken to make it clear that a delusion is a belief which would be incredible to sane people of the same class, education or race. The reason of this is that sane people often entertain beliefs which are so strange, and erratic and false to the facts of life, that by themselves alone they might seem to be genuine insane delusions. Carefully investigated, however, they are seen to have a consistent connection with the expressed views, or actions, or conduct, or mode of life of those who hold them. Strange superstitions are usually mentioned as instances; also unusual religious views; eccentricities of conduct so unusual as to suggest mental unsoundness.

Insane delusions may grow out of exaggerated, extreme or over-wrought beliefs. Emotional people of sensitive, high-strung nature, liable to go to extremes,

⁶ Nervous and Mental Diseases, Landon Carter Gray, p. 587.

² Natural History of the Intellect, R. W. Emerson, p. 24.

or ignorant people, also of the emotional kind and easily influenced, cannot, when sane, be regarded as well-balanced, and, under the strain of the trials of life, or ill-health, can easily pass over the narrow line which separates the sane from the insane. One can often trace the genesis of the delusion, as it is slowly evolved, and see from what it originated, in this particular class of cases, but it is necessary to be careful, and not label a delusion an insane one until fully evolved.

When once delusions are fully formed, they are no longer reasoned and speculated about, as is the case with insistent ideas. They are the very heart and essence of the *ego* itself. They are the new personality, which has taken the place of the old one, whatever that might have been, and it is from this new standpoint that the I, the *ego*, looks out and gazes on the world around him, and judges what shall be his attitude towards it. There is no longer any thought that he can be in the wrong, or that anything is unnatural about him. However depressed, sad, miserable, or exalted or happy he may be, he now sees things clearly in their true light exactly as they actually are. If any one disagrees with him, or tries to argue him out of his false beliefs, even if such a person is listened to, he is commiserated for his ignorance, shown that he cannot comprehend the true state of affairs, or is regarded as unbalanced himself.

The extraordinary hold that delusions have over the insane is illustrated by the way they treat each other in hospitals. Often they are quick to perceive each other's delusions, and in their mutual treatment are kind and forbearing, fully recognizing how much allowance must be made for people who are controlled by erratic notions and foolish ideas. They even will try to argue each other out of their delusions, and use much tact and skill in doing so. Frequently when I see how completely a person is held in bondage by his false beliefs, yet receptive of certain kinds of impressions; see him eating, dressing, working, amusing himself, precisely as do other people, yet in a world of his own which I cannot reach, I feel as if he were hypnotized; as if only one part of his brain was working, while the other portions slept. And so to some extent he is the victim of auto-suggestions, made so often, that at last they come to have an organized, living character. I am sometimes so much impressed by the patient's being in this hypnotic state, that I search persistently for clues to the suggestions which he has made to himself, to see if I cannot replace them by counter-suggestions to gradually offset them. I am not now speaking of hypnotism, to which I shall refer under the head of therapeutics, but simply of the substitution of suggestions in the mind of the patient.

It may help you, perhaps, to look at an insane person as if he were hypnotized. Think of his having some rather unusual false belief, such as that he is a teapot (Bucknill and Tuke), or made of butter (Régis), or has glass legs, or a snake in his stomach, or has a sponge in his head instead of a brain (Kirchhoff). Then picture to yourself what a man might say, do, and feel, if he had been hypnotized to believe such things, yet at the same time was obliged to conform to social requirements as far as was possible. It would seem as if the incongruity of the situation must make it impossible to play such a part, but it does not. The hypnotized person, as you all know, will do the most ridiculous things with calm and imperturbable gravity, for the reason that only one portion of his mind is

alert and wide awake. The intelligence of the other portion, which under conditions would be active, is "switched off" as James says, and is temporarily dead. The power of comparing, which would at once reveal the absurdity of things, is held in abeyance, for only one portion of the *ego*, that interested in the special suggestion, or set of suggestions, asserts itself above the "threshold of consciousness." I would not say that the insane person and the hypnotized person are in a similar morbid condition, but there is a rather striking analogy in some ways between them, a knowledge of which will make you feel more familiar with mental disease.

(To be continued.)

Original Articles.

SOME RECOLLECTIONS OF THE TWELFTH INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.¹

BY FRANCIS S. WATSON, M.D., BOSTON.

At the suggestion of our President, Dr. Mason, I have put together the notes of such of my recollections of the recent Congress in Moscow as seemed most likely to be of interest to the Society. I must ask your indulgence for the lack of sequence and absence of systematic arrangement, for they are written in the order in which the events occurred to me personally, and I have made no attempt to classify them.

I will ask you then to begin with me at the Russian frontier. The first evidence of the generous scale of the management of the Congress was the railroad pass, which gave free passage from the frontier to Moscow and back again, over any of the direct routes. This had been promptly forwarded to me in London on application by letter. These passes were given to every member of the Congress, and at a rough calculation must have cost the government in the neighborhood of half a million dollars.

I found no Russian train officials who spoke any language but their own. This was true also of some of the hotels, and many of the shops, more especially of those in Moscow. In St. Petersburg, German, at least, was generally spoken.

Railroad travel in Russia is comfortable. Broad-gauge tracks allow spacious cars, and the dining-cars, lighted with numerous large candles, are admirably furnished and served. The rate of travel is slow, rarely exceeding twenty-five miles an hour. At the stations there were no trucks to move baggage, but each piece was carried separately by very deliberate railway porters.

St. Petersburg was lavishly decorated with flags and gay-colored bunting in honor of the birthday of the Dowager Empress, and in anticipation of the visit of the German Kaiser and Kaiserin; and even in the dead season of midsummer, the town was again filled by the various military and civil officials, who had returned to take part in these ceremonial events.

On the next day I went to visit the Marien Hospital, which is the best in St. Petersburg, and was cordially received by its resident superintendent, General Pavlov, who has recently resigned the professorship of surgery in the St. Petersburg Academy, which he held for twenty-four years.

¹ Read before the Boston Society for Medical Improvement, November 1, 1897.

We are accustomed to consider the "hustler," as our slang terms him, a product peculiar to American soil; but Professor Pavlov's daily routine of work dispels this idea. In addition to the duties of superintendent of this hospital of about 450 beds, he carries on a large private practice, is body surgeon to the Czar, has numerous duties connected with his military position, and has a private hospital of forty beds which he uses for the surgical cases amongst his own private patients.

The Marien Hospital was built a little more than a hundred years ago, and accommodates 140 patients in its surgical division. The construction of this part of the buildings was, of course, unsuitable to the practice of modern aseptic surgery, but the wards and operating-rooms devoted to this work have been altered to meet the requirements, and now have all the essentials for carrying out thorough aseptic work, which is in successful operation. This end has been secured in a thoroughly practical manner, at a relatively small expense, and its success is contributed to by the thorough drilling of the nurses and attendants, which seemed to me notably good.

The character of the furniture and aseptic appliances are shown in the accompanying illustrations. The apparatus for sterilizing by heat is built into the wall which separates the rooms in which the dressings are prepared, and instruments are kept previous to sterilization — and the operating-room. An iron door opens at either end of the sterilizer into each of the rooms, so that the articles to be sterilized are put in at one end and taken out at the other, ready for use, directly into the room where they are needed. The walls of the operating-rooms are of hard-finished plaster covered with glazed paint, the floors of cement. The custom which has been generally given up elsewhere is still in vogue here, namely, that of washing the operating-room with a carbolic solution applied through a hose, and also of filling it with steam about three hours before operating, with the view to precipitating all dry particles. The temperature of these rooms is kept very high during operations, heat being supplied by large porcelain stoves in which wood is burned.

The senior surgeon of the staff, Dr. Trachtenberg, is another example of the arduous demands of this hospital, in that no operation requiring an anesthetic is allowed to be performed in his absence, whether night or day. He has a continuous service, taking three months' vacation each year. Under his direction are nine other surgeons, also having continuous services, each taking about six weeks' vacation annually. These nine associates are under the control of Trachtenberg and are of equal rank. Seven are on duty in the house, and two in the out-patient department at the same time, and exchange these services in rotation. Each has twenty beds under his special care, and each in turn does all the operations deputed to him by Trachtenberg for ten days at a time, being assisted by his colleagues. The house-surgeons have but a small share in the immediate assisting at operations in the hospital, and get most of their practical experience in the out-patient department.

I saw the removal of an ovarian cyst with a twisted pedicle performed by the first assistant surgeon. The operation was carefully, deliberately, and safely performed, but without much technical style or finish. The nurses wore white sterilized gowns and caps, the former having short sleeves leaving the arms entirely bare. Four nurses were present at this operation.

The dressings and sponges are kept in round, covered tin boxes. One nurse has the exclusive duty of banding these to the surgeon as they are required, and keeping them from all contamination during the operation. A second has charge of needles and sutures, ligatures and instruments. A third cleanses and replaces the instruments as they are used, and a fourth has general care of the room, bringing additional supplies, keeping the tables clear, floors clean, etc. Long tapes were employed, with snap forceps attached to one end and firmly fastened by the other to the gauze pads used for packing in the abdominal cavity during the operation, the forceps hanging over the edge of the table to avoid the danger of leaving sponges in the abdominal cavity, and to obviate the necessity of keeping count of them.

Anesthesia is begun by bromo-ethyl, and continued with chloroform, ether having been abandoned after two years' continued trial because of the frequent occurrence of bronchitis and pneumonia following its administration. I noticed that the patient I saw operated upon vomited subsequently, quite as much as we are accustomed to see them do after ether here.

The dressing often used is sterilized moss, or wood fibre made into pads by covering with gauze. The wood fibre, instead of brushes, is also used for washing hands. Some of the surgeons here operate in, and have their assistants also wear, thin white sterilized cotton gloves. The surgical wards were clean, well cared for and comfortable, the low beds being their only bad feature.

In Professor Pavlov's private hospital, to which reference has been made, the outer air is everywhere filtered through wool wadding, which is placed in the ventilators of every room; and in the case of the operating-room, the air is sterilized by heat also. All the arrangements of this hospital were admirable, including the quarters for the nurses, who are members of the Red Cross Society.

The rest of the time in St. Petersburg was largely occupied by the Kaiser's visit and its attending ceremonials, which it would not be appropriate to describe here.

The first impression of Moscow is distinctly disappointing, the drive from the railway to the hotels being through a part of the town which gives no hint of its remarkable beauties. The cobble-stone street pavements are of the roughest, and one is driven over them at a rapid speed, in small open cabs innocent of springs, being jolted about in a manner that makes all other bodily exercise unnecessary for the rest of the day. Clouds of dust pervaded the streets, and the temperature ranged between 85° and 95° F. during the two weeks of my stay. If the first impression of the town is not an agreeable one, it is dispelled and wholly altered from the moment that one enters the enclosure of the Kremlin, with its numerous remarkable buildings and historical associations, and looks out over the most wonderful panorama presented by any town in the world, stretching as far as one can see over the plain, with its varied and harmonious coloring, and its sixteen hundred spires, turrets, and minarets rising above it. There at once the peculiar enchantment of the place enters one, and steadily grows the longer one stays.

It was an advantage to go, as I did, to Moscow ten days before the Medical Congress opened, for it gave the opportunity to make the acquaintance of the sur-

geons there, to see the town, to watch the preparations for the Congress and judge of their efficiency, and to become familiar with some of the medical institutions. Of the latter the two most interesting, I thought, were the Clinic of the Faculty, and the Foundling Hospital. The latter is, so far as I know, unique and certainly the most remarkable that I have ever seen. It is approached through a broad avenue shaded by large trees; on either side is a high wall, beyond which are gardens. At the top of a wide flight of steps in front of the entrance there stands an official who is a striking figure—a man well over six feet, dressed in a caped and long-skirted, bright scarlet coat, lavishly trimmed with gold lace. He had a handsome face, with moustache and long flowing side-whiskers, and a thick mass of hair cut rather short and standing erect, all white; and he held in his hand a long gold-headed cane. Upon sending our cards to the superintendent, one of the assistants, a woman, was detailed to show us over the insti-

thousand who were that day inmates of the institution, to which must be added about a hundred more who were within doors, some being kept alive in incubators, and others who were the subjects of various diseases.

The women who attend these illegitimate children are either their mothers, or wet nurses paid by the State for this purpose. Each of those who are mothers of an illegitimate offspring is obliged to suckle not only her own child which she brings there with her, but also that of some other woman, who has not taken her baby there but has left it in the streets instead; the number of the latter class is sufficient to oblige the mothers who come with their children to do double nursing duty, and also necessitates the employment of paid wet nurses. Considerably more than half of the women I saw there that day were mothers of one of the children they were nursing.

Every woman who brings her infant to the institution is obliged to pay a fee of about twelve dollars in

FIG. 1.—Professor Sklifosowski.

FIG. 2.—Professor Bobrow.

tution. She took us to a gate in the wall bordering the avenue, and opened it upon one of the most singular and picturesque sights imaginable. A broad, sanded path extended from the gate for a distance of about three hundred yards, shaded by two rows of fine trees and forming one side of a pretty garden of about four acres; on either side of this pathway stood a line of women, about five hundred in number; they were divided into three companies, by short intervals of distance, and each company wore a costume of the same form but of different color. The skirts of all were white. The first company wore red and white bodices and red caps; the second, blue and white bodices and blue caps; the third, green and white bodices and green caps. The blue was worn by those who were caring for infants with diseases of the eyes, the green by those caring for infants of premature birth, and the red for the children who were free from disease. In front of each woman stood a baby-carriage containing *two* illegitimate children, in all about a

order to gain admission for herself and the child. This regulation has, however, only been in operation for the last few years; formerly all applicants were received gratuitously.

The children are allowed to remain for six weeks, and then, unless the mothers wish to keep them, are sent to be cared for in various families in the country who make a business of taking them, and bringing them up by hand, and who keep them until they are thirteen years of age, during which time they are maintained at the expense of the State. After this, they are apprenticed to trades and then must take care of themselves. The mortality of these children while they remain in the institution is about 40 per cent.

The mothers were for the most part of the peasant or poor laboring class, and evidently did not associate any sense of shame with the fact of the illegitimacy of their offspring. They were all unaffectedly pleased if one noticed their babies, and held them up for approval with a simple and gratified smile. They were

a strong, healthy lot of women, as a rule, but singularly lacking in feminine charms and good looks, and most of them were no longer very young. I saw but six comely forms and faces amongst them all.

About ten thousand illegitimate children pass through this institution annually. There is also a lying-in ward connected with this hospital, but I did not inquire into its details.

The second institution of which I will speak is the Surgical Clinic. This was founded in 1846.

The professor of surgery, J. Inozentsen, was sent to various countries to study the administration and practice of their hospitals; and, following his report to the minister of education, a surgical hospital of fifty beds was founded.

In 1880 Professor Sklifosowski was appointed to the professorship of surgery, and conducted the clinics until a few years ago, when he accepted an appointment at St. Petersburg, and was succeeded by Prof.

illustration. There are also two smaller operating-rooms, well lighted, and furnished with all the needful appliances for carrying out aseptic work.

As in the hospitals which I saw in St. Petersburg, all the essentials for the best modern surgical work were present, and have been secured at a comparatively small cost. They lack the beauty of finish and the costly materials which we have become accustomed to see in our hospitals here; but for all practical purposes they are well equipped, and in the drill and discipline of their hospital attendants they seemed to me to be superior.

There was one contrivance there which we would do well to adopt, a simple method of transferring the patients to and from the operating-rooms without taking them from their beds. The bed is jacked up upon a pair of small rubber-tired wheels placed beneath each end, the crossbar at each end of the bed being caught in iron arms placed upon a strong rod above

FIG. 3. — Surgical Clinic.

A. A. Bobrow, who is the present incumbent. These two gentlemen (Figs. 1 and 2) were respectively the President of the recent Congress, and Chairman of the Executive Committee of the Surgical Section, in which capacities they showed great executive ability and tact; and much of the credit for the admirable organization and the smooth running of the machinery of the Congress was due to their efforts.

The surgical department of the clinic has the capacity now of eighty beds, is a handsome building just outside the town, where it forms one of the extensive group devoted to various other branches of medicine, which together constitute the hospital of the Clinic of the Faculty. The illustrations are of its exterior, the amphitheatre and one of the smaller operating-rooms (Figs. 3, 4, 5). With its furnishings and appliances it cost a little less than one hundred thousand dollars. The department has an amphitheatre with a seating capacity for three hundred persons. It is built in the peculiar form which is shown in the accompanying

the wheels, and the bed lifted by depressing two long handles, which are also connected with the wheels, and by which the bed is transported by an attendant placed between the handles of each pair of wheels. In this way the bed with the patient in it is moved from its place in the ward directly to the side of the operating-table, the patient is anesthetized in the bed and then placed upon the operating-table, the bed is arranged and made ready to receive the patient at the end of the operation (Fig. 6).

There was nothing specially noteworthy in the details of the aseptic work. The wards of the hospital were clean and well ventilated, and the patients evidently well cared for; altogether the institution compares favorably with the best ones of other countries.

I had the pleasure of seeing Prof. A. A. Bobrow perform two suprapubic lithotomies; the bladder was closed by complete suture in both cases. The operations were carefully and skilfully done, and the technique was excellent. The professor is ably assisted

by the two assistant surgeons (*professeurs agrégés*), MM. S. P. Fedorow and S. M. Roudnew. From these gentlemen I met a cordial welcome, uniform kindness and courtesy throughout my visit.

The dedication of Pirogoff's monument took place about a week before the opening of the Congress. The statue is of bronze, and represents the great Russian surgeon seated in a chair, and is said to be an admirable likeness of him. It is placed in front of the Surgical

They worked like beavers, and deserve the thanks of all for their uniform courtesy and efficiency. Some of them were deputed to meet the members at the railway stations, not only at Moscow but in St. Petersburg and some of the larger towns as well; to offer their services in securing lodgings and to assist in any way the members might wish, both on coming to and going from the Congress. This service was by no means an empty formality, for, owing to the visits of the German

FIG. 4. — The Amphitheatre.

FIG. 5. — The Laparotomy Room.

Clinic. On the day of dedication a platform had been raised about its base, and upon it were gathered many of the notable physicians and surgeons of Russia. Directly in front of the statue stood a lady who followed with marked attention the words of the speakers. This was Pirogoff's wife, who is now eighty-four years of age. The ceremonies were opened with prayers by two priests, who wore the long robes and tall sugar-loaf-shaped hats of the Russian Church. They were followed by a choir of male voices; then came the speeches and the unveiling of the monument; after which a reception was held in the hospital.

Finally came the time for the opening of the Congress. But few of its members arrived until two days beforehand, so that the officials having the arrangements in charge were suddenly faced with the by no means easy task of registering and supplying information to about eight thousand men who descended upon them like a flight of locusts, all expecting to be attended to at once, and some of them being disposed to grumble because this impossible task could not be performed.

The government had put the great military riding academy at the disposition of the Congress, and it was here that the members went to register their names and to receive their cards of membership, etc. The floor space was divided by temporary partitions into bureaus for the different sections, restaurants, post-office and central bureau. This building, which it may be said in passing has the largest unsupported ceiling in the world, is near the principal hotels. The hotel proprietors had been informed of the details of the arrangements for the Congress, and were able to direct their guests to the places of meeting of the Sections, etc.

Some of the best work, and certainly the most arduous, was done by the volunteer corps of medical students, who were detailed to fill out the cards of membership, of invitation to the various entertainments, etc.

Kaiser, the French President, and the nearly simultaneous meetings of the Medical, Statisticians, and Geological Congresses, Russia was crowded with visitors to a degree that taxed her means of transport and accommodation to the utmost.

The Congress first met in general assembly in the opera house, which is certainly one of the most beauti-

FIG. 6. — Method of Transferring the Patients.

ful theatres in the world, but only about one-half of its members could be accommodated in it, although the stage as well as the auditorium was occupied. The scene was a striking one, and the bright uniforms worn by a large number of those present added greatly to the effect. The stage was occupied by the State officials, the officers of the Congress and the delegates from the different countries; in the centre sat the Grand Duke Serge, having on his right the Mayor of Moscow and the Minister of Education, and on his left Profes-

sor Sklifosowski, President of the Congress and of its Surgical Section. The Congress was formally opened by the Grand Duke in a few words of welcome. He was followed by the Mayor, the Minister of Education and Professor Sklifosowski. Professor Roth, the indefatigable Secretary of the Congress, then read his report, which included the statement of the numbers of the foreign members present, amongst which that of the United States was regrettably small, there being but 120, very few of whom were from the Eastern section of the country. Then the delegates of the various nations were called upon to speak for their respective countries, Professor Kohle, of Berlin, being the first. The sequence was tactfully arranged in such a way that the delegates of the smaller nations were interspersed with those of the larger ones, and not left till the end.

Our country was admirably represented on this occasion by Dr. William S. Thayer, of Johns Hopkins University, who unexpectedly to himself was called upon to fulfil this somewhat difficult task, of which he acquitted himself in a highly satisfactory manner.

The representative of Japan created the liveliest interest of all the delegates; he was almost the only one who did not speak in his own tongue, but made an admirable address in German, which was greeted by hearty applause. Among the other delegates who spoke were Sir Wm. Mac Cormac, Virchow, Ziemssen and Du Jardin-Beaumetz.

On the following day the regular business of the Congress began, the Sections meeting in the various halls of the large building known as the *Salle de Noblesse*, which is centrally situated, and is sort of a fashionable club, used by its members in the winter season for balls, concerts and entertainments. Its many spacious rooms gave ample accommodation for all the Sections.

The hall in which the Surgical Section met was as comfortable as any room could be with the temperature in the nineties, where it remained throughout the eight days of the Congress. At one side of the room was a platform which was occupied by the Honorary Presidents of the Section, of whom there were two from each country. Among them were Macewen of Glasgow, Launelougue of Paris, Gussenbauer of Vienna, Roux of Lausanne, Scriba of Tokio, Rose of Berlin, Bottini of Padua, Tillaux of Paris, Sir William Mac Cormac of London, Czerny of Heidelberg, Küster of Marburg and many other well-known names.

There were two sessions, of three hours each, daily, each one being presided over by one of the Honorary Presidents in turn, in alphabetical order. While there were no remarkable new surgical departures brought forward, the contributions presented were of a high order. The French speakers, as usual, threw into the shade those of other nations by the telling power of their language and their vivid way of using it. Tuffier and Albarran were conspicuously good. The communications offered showed but little tendency to conservatism with regard to operations, but rather the contrary, as was seen, for example, in the advocacy of more radical and extensive operations upon the lungs. It was gratifying, especially for a Bostonian, to hear the strong defence of Bigelow's litholapaxy, which was made in a very convincing way by Albarran.

A certain number of surgeons operated, by invitation, in the amphitheatre of the Surgical Clinic, among others Doyen, who demonstrated his instruments for cerebral operations. Dr. Calot showed his method of

forcible straightening of the vertebræ in Pott's disease, and exhibited patients in whom this had been successfully done.

Among the more interesting papers read before the Section may be mentioned those of Tuffier and Macewen, on the surgery of the lungs, that of the former dealing with cases of tuberculous cavities and gangrene; both surgeons urged excision in a certain class of cases of the former of these conditions, and reported examples which showed the benefit of such treatment. The paper of Credé, of Dresden, upon the use of silver as an antiseptic in wounds, and as a prophylactic measure against various infections, was interesting. The preparations recommended by him are the lactate and citrate; the latter is a white, odorless powder, soluble in water or wound secretions, in the proportion of 1-3,800; it is absolutely unirritating and is not a poison. For the purpose of disinfecting wounds, and for preventing subsequent infection it is applied as a powder thinly sprinkled over the surface. In solution, in the proportion of 1-8,000, up to the strength of 1-500 to 1-2,000, it is used in the throat, eye, bladder, urethra, etc. It is a much more powerful germicide than corrosive sublimate, and is free from the objectionable qualities of the latter.

ENTERTAINMENTS.

There were a number of public and private entertainments during the Congress. Perhaps the most interesting of them was the general reception for the members of the Congress and the ladies who accompanied them, which was held on the first evening in the Chamber of Commerce, an immense building, about as long as a block and a half of town houses, and about 200 feet wide. Within the space inclosed by its walls are three parallel glass roofed arcades, separated by two long rows of shops two stories high, which are placed one between the centre and right-hand and one between the centre and left-hand passages respectively. The second stories are connected by bridges across the passageways. The lines of shops are broken at intervals by cross-passages, which are also bridged. On the ground-floor at the intersection of the passages there are carrefours of circular form, in the centre of which are fountains which, on this occasion, were playing in jets of various colors. At one end of the central passage a military band and at the other a fine orchestra played in alternation. In some of the alcoves which occurred at intervals along the side passages temporary stages had been placed, on which were given, by companies of players or choruses of singers, national songs and dances of different provinces of Russia. On some of the bridges connecting the galleries there were choruses of soldiers, the singing of one of them, the Cossacks, was very interesting. The long lines of shops were brilliantly lighted and the galleries gaily decorated. Altogether such a scene would be difficult to surpass either in novelty or beauty.

On another evening, in the *Salle de Noblesse*, there was a ball preceded by a concert; and one of the pleasantest evenings was that passed by a few of the members, at the invitation of Professor Sklifosowski, in listening to the singing of the choir of the Church of St. Sauveur. In this choir were some bass voices such as are only to be found in Russia, and which surpass all that I have ever heard in power and in beauty of tone.

On the evening before the last one of the session came the dinners of the various Sections; these were held in different restaurants, many of which have very large halls.

The dinner of the Surgical Section was largely attended, and was an interesting occasion. Professor Sklifosowski presided, and excellent speeches were made by Le Dentu, Macewen, Kocher and others; amongst them was one by a Russian, who said that his mind had become so confused by the babel of tongues that he was no longer capable of expressing himself in any one language and that we must excuse him if his speech seemed rather mixed in consequence; and in truth his speech was compounded of a number of tongues, which were, to some of us at any rate, very strange indeed. It was a very clever and amusing performance.

A committee of ladies, with the Grand Duchess at its head, had charge of entertaining the ladies who accompanied the members, and contributed their full share to the success of the Congress. Excursions to the environs of Moscow were among the pleasantest features of their programme. The Grand Duchess, who, it will be remembered, is the Czarina's sister, interested herself actively in the work of this committee.

In concluding this short sketch, let me say that the management of the Congress was in all respects admirable. It was planned and carried out on a large and generous scale, and it was evident that our Russian *confrères* who were concerned in it had put their shoulders to the wheel, and spared themselves no pains to assure its success. The remarkable facilities offered by the number of large buildings in Moscow and their central positions contributed to this result. The courtesy of our Russian hosts and their evident wish to please their visitors were conspicuous.

Amongst other things to be remembered are the deep-toned bells, the devoutness of the people as shown in the churches and before the shrines, or *Ikons*, as they are called, which are placed at frequent intervals in the streets, in passing which almost every Russian removes his hat and crosses himself, and in front of which are often to be seen people kneeling in prayer, heading forward from time to time and touching their foreheads to the pavement.

Then, other features of the country are the great number of fine horses and the universally rapid driving; the absence of small towns along the lines of the railways; the great number of police in the large towns; the presence of military patrols along either side of the railways, soldiers being placed within sight of each other sometimes for a distance of one hundred miles or more; and the customs of eating and drinking, to which one needs to be trained before reaching the level of the Russian's digestive powers.

One memory, which is strong with me, is that of the almost entire absence of laughter; smiles were not uncommon, but I think I can truly say that I heard no one laugh throughout the weeks I was there. One other custom which one has to learn to adapt one's self to is that of turning night into day. All the entertainments begin late, and the people seldom went home from them before three or four o'clock in the morning.

Yankee haste meets no encouragement in Russia; and the length of time they take to do things in the shops, hotels and railways, at least, is only surpassed by the deliberation of the negro of our own Southern States.

Let me say that, should we hold an International Congress here, we would do well to imitate as nearly as possible the manner of conducting it shown by the Russians last summer; and the more nearly we come to doing this the more successful will the occasion be.

ACUTE INFLAMMATION OF THE ANTRUM OF HIGHMORE.¹

BY FREDERIC C. COBB, M.D.,

Assistant for Diseases of the Throat, Massachusetts General Hospital; Physician to Throat Department, Boston Dispensary.

So much has already been written on the subject of inflammation of the antrum that it seems superfluous to add anything to the already enormous volume. Purulent antral inflammations may be divided into three classes: first, acute attacks associated with complete closure of the antral orifice; second, acute pus formation, with a more or less patent condition of the antral opening; and, third, chronic suppuration without any marked symptoms of obstruction.

It is to the second class of cases that I wish to call your attention. The symptoms observed in this affection are usually ushered in by a "cold" in the head, with perhaps a chill or severe pain in the frontal region or over the antrum itself. The "cold" may at first be bilateral, the antral condition only be suspected after the rhinitis has cleared up partially, leaving behind it a unilateral nasal discharge of thin or thick yellow or greenish character. There may or may not be a foul odor connected with the disease, and generally when present it is not perceptible to the friends of the patient but is extremely offensive to the patient himself. The character of the pain is intermittent, the intermissions being associated with a free discharge of pus from the nose or from the posterior nares. On transillumination the face appears dark under the eye of the affected side, and often light cannot be perceived in the eye of the diseased side as well as on the healthy one. The darkness is to be explained, not as is usually understood, by the presence of pus in the antrum, for we find that on washing out the cavity after trephining that the affected side remains as dark as before, but by the great thickening of the antral mucous membrane, resulting either from the constant presence of pus in the antrum or by the inflammation set up in the mucous membrane by the etiological factor of the antral disease itself.

We have now established with considerable probability the presence of pus in the antrum, but can still be misled by one factor, the anatomical difference in the thickness of antral walls and the size of the antral cavity itself. In order to be absolutely certain of the condition at the time of examination it is necessary to puncture the antrum, either through the lower meatus in the nose or through the canine fossa or alveolar process. In my experience, however, this is seldom necessary, as I have found transillumination a very satisfactory guide when taken in conjunction with other symptoms. Having determined that the antrum contains pus, the next step consists in finding the etiological factor in its production.

The teeth should be thoroughly examined, and, if possible, by a first-rate dentist, and any account of pain or filling of dead roots inquired into with great care.

¹ Read before the Boston Society for Medical Improvement, November 1, 1897.

Grünwald has shown that diseased tooth crowns as well as roots may give rise to an empyema. If there be nothing found amiss with the teeth, the nose should next be carefully examined for any signs of obstruction which could cause stoppage of the antral orifice. Ethmoiditis and frontal disease must be eliminated if possible, by examination with the probe for necrosed or bare bone in the region of the middle turbinate. Fillebrown has shown by the passage of a probe from the frontal sinus into the antrum, and I have satisfied myself by injecting colored fluids into the frontal sinus, that there exists a frequent natural communication between the frontal sinus and the antrum through the infundibulum. This fact has been well known to anatomists for a long time, but its significance in antral affections has not been appreciated by practitioners. If there are no signs of inflammation in either frontal or ethmoid regions, we are left to diagnose antral empyema, and the question of drainage at once presents itself. Pus in the antrum has usually been considered a good indication for at once opening that cavity. But the opening of the antrum, although at the top of the cavity in the erect position, is, in the recumbent position, parallel to its long axis, and offers free drainage if the patient lie on the healthy side, and if the middle turbinate does not obstruct the passage of the pus into the nose.

The object of this paper is to show that the antrum may, and often does, get well without other treatment than keeping the turbinate contracted and the nose as clean as possible. It may be objected that the process is a slow one under the expectant treatment, and would be rapid under the policy of interference. Fatal cases have, however, been reported from sepsis following the antral opening, and very severe hemorrhage is also a possibility which has occurred and has to be considered. On the other hand, we must consider what damage to the antral mucous membrane may be done by waiting a few weeks before operating. With regard to the latter point, the statistics show a most remarkable power of recovery in the mucous membrane of the antrum, cases being reported where, foreign bodies being removed from antra which has been suppurating for months and even years, healing took place very rapidly on removal of the cause. The following case is an instance of this:

A. C. entered the Boston Dispensary complaining of a foul discharge from the left nostril. Five months before she had had a severe cold in the head, but this seems to have been on the left side only. Examination shows a first bicuspid the crown of which only was decayed; but as all the other teeth were missing on the upper jaw on the side, it was decided to remove the tooth. A little cavity in the crown was found, but the roots were reported perfectly sound. A week later the antrum was opened through the alveolar process at about the location of the insertion of the second molar tooth, and much foul pus was evacuated. A week after operation, with daily washing, the wash-water showed no pus, although the antrum still appeared as dark as before puncture when transilluminated. The catheter was now passed every day into the antrum, in order to keep the opening from closing in case of a relapse; but as none occurred in ten days the opening was allowed to close. Three weeks after opening the antrum the right side, although still somewhat darker than its fellow, was much brighter than before. Five weeks after, however, transillumination showed an

equal light on both sides and the patient eighteen months later still reports herself perfectly well.

This case shows, I think, that the mucous membrane after five months of constant suppuration may regain its equilibrium so as not to secrete pus in a week or so although it may not return to its absolutely normal condition for four weeks. It also confirms Grünwald's statement that the diseased crown of a tooth may give rise to an empyema even if the roots of the tooth be sound. If, then, the antral mucous membrane recovers so rapidly when it is washed and drained, even if it has been in a condition of suppuration for many months, we need not fear to wait a week or two before opening and draining. That the antrum can be clearly proved to be full of pus and its mucous membrane infiltrated and yet that it can recover rapidly without operation is, I think, shown by the following cases:

CASE I. Miss E. F. came to me in March, 1897, with a severe rhinitis. This began on March 1st; and on the 5th, for its relief, the nostrils were cleansed with Seiler's solution by means of a spray. On the 9th she began to feel a sensation of pressure in the upper left molars, as if her teeth were crowded together. Her face swelled considerably on the same side, and on the 10th there was a discharge of pus from the left nostril, and all the symptoms began to abate. The teeth had been constantly examined by Dr. F. M. Briggs, and nothing could be found diseased about them in any way. On the 13th, the swelling of the face having subsided, transillumination showed darkness of the left side. The symptoms continuing to improve no operation was done, the treatment being confined to oily nasal sprays and cleansing washes. On examination of the nostril pus was clearly seen beneath oozing from the middle turbinate, which was slightly swollen and edematous. The discharge of pus decreased, the secretion becoming thicker and less in amount quite rapidly. At the end of three weeks the discharge had ceased entirely, and on the first day of April transillumination showed equal light on both sides of the face. There has been no return of the symptoms.

CASE II. R. P., a man thirty-one years of age, seen with Dr. Cogswell, of Boston, had a sharp attack of rhinitis March 10, 1895, with pain over left antrum and at root of nose. In two or three days the acute cold subsided, and the pain over the left antrum and frontal region became more acute. I saw him on March 16th, and found the left nostril excoriated by a thin purulent discharge, which was so profuse that it was hard to tell whether it came from above or below the middle turbinate. The lower turbinate was much swollen. Transillumination showed the antrum of left side quite dark, in great contrast to the other side. Although the antrum was evidently full of pus it was not considered wise to open it, on the principle before stated, that it was more likely to be the reservoir for the frontal sinus which the frontal pain seemed to make the probable seat of the disease. Under oily sprays to reduce the violently inflamed condition of the nostril the pain began to improve, growing less each day and soon disappearing altogether. The discharge began to improve, but slowly, and becoming thicker and more muco-purulent. It ceased in about three weeks, and the patient having no further symptoms was not seen until April 6, 1897, when transillumination showed both sides of the face perfectly equal in the transmission of light.

CASE III. Mrs. A. L. A., age forty-six. Duration, previous to operation, one week; thin yellow discharge from right side of nose. Also purulent otitis of same side; discharge is becoming more watery. On examination, left nostril clear; right nostril shows normal-sized turbinates, while from under the middle one pus is seen to be oozing. There was no polyp. Transillumination shows darkness below right eye and over right cheek. There were no teeth in the right upper alveolus. The discharge improved slowly in character, first thick and then watery; and on March 9th there was no discharge, although transillumination still showed darkness of the right side. The patient had no further trouble, returning to the hospital on September 13th for some other complaint, transillumination was found normal on both sides.

Both these cases were nervous, timid people, to whom the idea of operation was very repugnant and to whom any surgical procedure, however simple, would have seemed terrible. I am sure that they were more comfortable than patients I have operated on either through the nose or alveolus. These cases are but an example of others of which I have unfortunately not kept accurate notes. They make the question whether to operate and at what time an interesting one. If the experience of others agrees with mine, it seems to me that unless symptoms of pressure or great pain, chills, etc., coexist with empyema of the antrum, it would be wise to give nature a chance to heal it. If, after the acute symptoms are over, the discharge shows no tendency to dry up, then puncture and wash. I do not believe that pus in the antrum, even for a long period, in any way prevents its ultimate healing when well washed and drained, so that we run no risk in permitting the process to run if there are no great signs of pressure.

TREATMENT OF CONGENITAL CLEFT PALATE BY MECHANISM.¹

BY GEORGE A. RAYMOND, D.D.S.

MR. PRESIDENT, MEMBERS OF THE SOCIETY, AND GENTLEMEN:—It gives me very great pleasure to come before this distinguished body to-night. It also gives me added pleasure that my paper should come on the same evening as that of Dr. Richardson, as I believe he will agree with me in the position which I take; and I believe firmly that the majority of our most able surgeons who have had much experience in dealing with cleft palates have arrived at the same conclusions.

It is not my purpose to give you any extended history or treatise on the subject before me, nor to take up your very valuable time in telling you what you already know.

We are all called upon to treat two kinds of cleft palate, namely, congenital and acquired. It is my purpose to-night to speak of the former, as the latter has to be dealt with according to the pathological conditions of each case.

The surgical operation known as staphyloraphy, or the closure of cleft palate, has been performed by some of our greatest surgeons for more than three-quarters of a century. The Germans, I believe, commenced surgical treatment about the same time as did our

American surgeons, working somewhat independently of each other, and yet reaching about the same results.

I believe it was as long ago as 1820 that the late and distinguished Dr. Warren first performed the operation in Boston. When I first undertook the treatment of these cases myself I immediately began a search in the records of the past, and have sought the information afforded me by those in the front ranks of our profession at the present day.

A little over a year ago I was to read a paper before the Maine Academy of Medicine on this subject, and I wrote to Dr. Norman W. Kingsley, of New York City, asking him if in his experience of forty years he had ever seen or heard of the staphyloraphic treatment resulting in a perfect articulation. In answer to my question he said that he had heard that there had been cases, but that he had never seen one. Continuing, he said, "I suppose it must be so, because some one says that he knew some one who said that he had seen such a case." In conclusion, he said, "We cannot deny the existence of such cases any more than we can deny the existence of the sea-serpent."

So, in my search for information, I find not a single case as having resulted in a perfect speech. Now, why is it that no one has ever been able to accomplish better results? Those of you who have examined any number of cases find that in the closure of the cleft the surgical palate will in all cases be short, and so tense that you can scarcely perceive any muscular activity or flexibility; therefore, while you may get a successful surgical palate, it is still far from being a physiological palate, as it is impossible for this new velum to come in contact with the posterior wall of the pharynx, thus shutting off the posterior nares.

About a year ago I had a young lady, twenty-three years old, come to me for whom Dr. Cheever had operated when she was a little child. I expected to have her here to-night that you might hear the speech yourselves, to see the results of an early operation. A few days ago I wrote to Dr. Cheever, calling his attention to her very bad speech and asking him his present opinion in the matter, and if after his long and noted experience he had known of a perfect speech resulting from such an operation. In reply he says, "The operations for the closure of cleft palate which I have done have usually disappointed me as to perfect articulation. The failures, I have observed, consist in lack of due flexibility of the soft palate."

The young lady whom I expected to have here not being present, I will show you a model of the mouth, and you can readily see how it would be more of a hindrance than otherwise to a perfect or normal speech. I see no reason myself why a cleft palate should be interfered with at all except to perfect the speech, as all the cases which I have been dealing with have not the slightest trouble with swallowing or in using fluid diet, and long before a child arrives at an adult age he has learned to accommodate himself to his condition.

A little over a year ago I saw a young child in Boston who had an operation for the closure of both hard and soft palate, including hare-lip. The lip had been closed in infancy but had torn open, leaving an ugly scar. In this operation (which was considered in advance of the usual operation) genius was displayed; but from my experience of twenty years in dealing with irregularities of the teeth and deformed

¹ Read before the Boston Society for Medical Improvement, March 8, 1897.

mouths as affecting one's articulation, I am firmly convinced that the child will never have a good speech.

If, perchance, you succeed in getting what may be considered the right length to the surgical velum in the child, and thus reach to the posterior wall of the pharynx, you will find that as the child grows and develops the last condition will be worse than the first, simply because there has been no commensurate enlargement or broadening of the soft palate. It will, therefore, be a hindrance to perfect speech.

Dr. James L. Little, of New York, once said, in speaking of uranoplasty and staphyloraphy: "I have carefully looked into the results and find that although in a large proportion of the cases the operations are successful so far as the closing of the fissure in the hard and soft palate is concerned, yet so little, if any, benefit is obtained in the improvement of the articulation that I have been forced to the conclusion that they should be discarded as surgical procedures in adults." Seeing also the results of the operation, even when done in childhood, what have we to conclude in the matter? We are convinced that the surgical procedure is a failure.

What you fail to get by a surgical palate we can get in all cases by the use of mechanism, and in the natural development of the child we can easily change the appliance to fit and perform the functions of a natural velum with the greatest accuracy.

I will now show you the phonographic record of the speech of a lady thirty years old who had worn her appliance about a year. She had a very wide congenital cleft and wears the appliance with perfect ease.

You will now hear her read an extract from American history without the appliance in her mouth.

She will now repeat "Nearer my God to Thee," with the appliance in her mouth.

I will show a little girl, ten years old, who has been wearing the appliance a year and a half. You can hear her speak in person. She has always been subject to severe tonsillitic inflammation, but a little less than a year ago quite a piece of each tonsil was cut away, so she is now able to wear the appliance night and day, only removing it to cleanse.

She will now speak without the appliance in her mouth.

She will now recite something with the appliance in her mouth.

I expected to have a young lady here for whom I have just made an appliance, but on account of sickness she is not able to be present.

I have associated with me Miss Sarah Allen Jordan, who is doing excellent work in teaching my patients in their articulation. Her special fitness enables her to supply the needs of these individual cases.

I have a little boy, who was placed in my hands by Dr. Hartwell, for whom I am now making an appliance. At a later period we will be able to show you, I think, in this case some very marked results. Before treatment you may be interested to have his speech by phonograph. This shows it as it is now.

When I was before the Maine Academy of Medicine my paper was discussed by Dr. Thomas Fillebrown, of this city, and I quote the following from his paper: "A serious objection to an obturator is that it is not practicable until the patient is well grown and the most susceptible part of his life gone, and the proper period for learning to talk has long since passed away."

I have shown you results to-night which are quite the opposite to his theory. I prefer to take such cases in early childhood, and I think I can truly say that I find it no more difficult to fit a child to an obturator who is seven or eight years old than for an adult.

Thanking you very kindly for your interest and the attention you have given me, I will conclude my remarks on this subject.

Clinical Department.

THREE CASES OF ABDOMINAL STAB-WOUND: LAPAROTOMY IN EACH CASE, WITH RECOVERY.

BY JOE V. MEIGS, M.D., LOWELL, MASS.,
Surgeon to St. John's Hospital.

THE three following cases occurred during my service in St. John's Hospital; two admitted in 1894 and one in 1895:

CASE I. E. M., single, age twenty-four, an operative. While engaged in a bar-room fight with several partially intoxicated companions he was stabbed several times by one of them with a jackknife which was recently used in cutting tobacco.

He was at once taken to his home near by, and while awaiting the arrival of the ambulance his protruding intestine was wrapped up in a much soiled undershirt. He was admitted to St. John's Hospital on the evening of May 5, 1894, an hour or two after the stabbing, somewhat under the influence of alcohol.

He presented the following wounds: A superficial wound one-half inch in length in the median line of the neck, two inches below the chin; a wound of the chest four inches below the left nipple, one inch in depth and one-half inch in length; a wound two inches in length on the inner side of the left thigh, six inches below Poupart's ligament; a wound two inches in length, two and one-half inches in depth, on the outer aspect of right thigh, about seven inches below the hip; a wound of the abdomen one and one-half inches long, one inch below and three inches to the left of the umbilicus, through which wound there protruded about ten inches of small intestine, which was penetrated just above the attachment of the mesentery by a wound three-quarters of an inch in length, running lengthwise. The intestine was wounded in two other places but not penetrated.

The abdominal wound was enlarged, the wound of the intestine was closed by Lembert sutures, silk being used. The remaining intestine was closely examined for other penetrations but none was found.

The abdominal cavity was flushed with sterile water and closed without drainage. Other wounds received appropriate treatment. Patient made a rapid recovery, and was discharged from the hospital four weeks after admission.

CASE II. P. O., single, age twenty-three, an operative. Received at hands of a companion the following wounds made with a pocket knife:

A lacerated wound of the ulnar side of the right hand, two inches in length; a wound of the little finger of the right hand, two inches in length; an incised wound of the abdomen penetrating the cavity, one-half inch in length, situated a little to the right of the umbilicus.

He was admitted to St. John's Hospital June 10, 1894. The abdominal wound was enlarged, intestine and omentum carefully examined and found to be uninjured. The cavity was flushed with sterile water and closed without drainage. Other wounds received proper dressing. Patient made an uninterrupted recovery, and was discharged, well, July 4, 1894.

CASE III. J. F., single, age twenty-three. Was admitted to St. John's Hospital on the evening of May 20, 1895, having been cut in a street fight. On examination the following wounds were found:

An incised wound on the dorsal aspect of the left hand, severing a tendon; a wound of the abdomen, two inches to the left and one-half inch below the umbilicus, three-quarters of an inch in length, with omentum protruding, seemingly strangulated.

The abdominal wound was enlarged, small wound of the omentum sutured, omentum replaced, intestines carefully examined but found uninjured.

The abdominal cavity was flushed with sterile water, and the abdominal wound closed without drainage. With the exception of a stitch-hole abscess, the patient made an uninterrupted recovery, and was discharged June 20, 1895.

Medical Progress.

RECENT PROGRESS IN LARYNGOLOGY.

BY A. COOLIDGE, JR., M.D., BOSTON.

ETHMOID DISEASE AND NASAL POLYPI.

As a result of the study of the pathological anatomy of ethmoid disease J. N. Mackenzie¹ concludes that the so-called "myxomatous degeneration," described by writers on ethmoid disease, is not due to mucous change at all, but is the result of simple inflammatory action. Purulent ethmoiditis may in many cases endure for years without producing any bone lesion whatever. The changes found represent successive stages of the same affection, and therefore divisions of "ethmoiditis" tend to introduce an element of confusion into our pathological conception of the disease. The ethmoid region affords probably the most excellent place for the study of the origin of so-called nasal polypi. Of great importance is the striking similarity between the young granulation tissue found in the ethmoid region and the structure of round-celled sarcoma, and hence the possibility of error in microscopic diagnosis. The author protests against the careless use of the term "myxoma" as applied to a growth which is histologically an edematous fibroma. Caries, when it occurs at all, is secondary, and of no etiological importance. Except in cases due to syphilis, tubercle, chemical poisons or trauma, it is not the rule to find necrosis, or even caries of bone. When the inflammatory process reaches the bone changes may take place in it similar to those found in atrophic rhinitis; that is, absorption and disappearance. In opposition to Grünwald, nasal polypi are not considered the result of suppuration, although in the vast majority of cases the result of inflammation. The development is as follows: the first stage consists in the formation of young granulation tissue, in the second this tissue becomes gradually converted into definite adult connective tissue, which in the third gradually separates and

causes more or less complete obliteration of the normal structures, and in the fourth converts them into a fibrous mass. This by its position becomes edematous, and assumes the characteristic forms.

Hajek² contributes a similar paper based on the examination of portions of the ethmoid bone and its coverings from patients with polypi and inflammatory hypertrophy of the mucous membrane. A polypus is simply an edematous hypertrophy, essentially of the same nature as a dense hypertrophy. The inflammatory process may be confined to the superficial layers, or extend deeper. Superficial inflammation may be the result of some continued irritation, and may precede, or be found in a different part of the same specimen, with infiltration extending to the glandular layer, the periosteum or the bone itself. When the bone is affected, it may result in new formation or in absorption of the bone, in the latter case leaving in places detached scales. The theory of Woakes, that necrosing ethmoiditis is a common and causative agent, has for some time been abandoned; there is seldom necrosis or caries of bone, except as an accidental complication, or as a result of syphilis or tubercle. The author's researches show that the inflammatory process extends from the outer to the deeper layers, and not in the opposite direction.

TUBERCULAR INFILTRATION OF FAUCIAL TONSILS AND ADENOID VEGETATIONS.

The finding of evidence of the invasion by the tubercle bacillus of hypertrophied pharyngeal and faucial tonsils, to which attention was drawn by Dieulafoy,³ two years ago, has suggested not only a point of entrance of tuberculosis into the system but a possible explanation of the hypertrophied glands themselves. The former possibility has been received with more favor than the latter. Different authors have found evidence of tubercle bacilli in faucial tonsils and adenoid vegetations after their removal. Such varying methods of examination have been used that it is not strange that the percentages in which such evidence was found has varied from one up to 20 or 30 per cent.; neither does the finding of tubercle bacilli on the surface of the gland or in the crypt necessarily point to the gland as a source of tubercular invasion.

McBride and Turner⁴ in one hundred cases found giant cells in three, but consider this percentage as too small.

Gourc,⁵ on the other hand, from a study of two hundred cases, believes that tubercle bacilli are very rarely to be found inside the gland; although frequently on the surface. Several other micro-organisms were found, but the author failed to find any tubercle bacilli or evidence of them when the growths had been previously cleansed.

Wright⁶ believes that, in spite of the recent evidence, tubercular amygdalitis is a rare affection, and that the tonsils are rarely the seat of primary inoculation. Investigations have shown that bacilli do get through the epithelium of the throat and into the cervical lymphatics in tuberculous subjects and in animals fed on tuberculous food. Considering the chances of primary, but especially of secondary invasion, it is certainly rather remarkable that these structures should escape so constantly as they do.

ANTITOXIN INJECTIONS IN OZENA.

In studying the bacteriology of ozena, Belfanti and Della Vedova⁷ found a bacillus apparently identical with the Klebs-Löffler bacillus of diphtheria, except in its virulence. Acting on this suggestion, they treated several cases by subcutaneous injections of the diphtheria antitoxin with surprisingly good results. These observations have found varying degrees of confirmation in the hands of other bacteriologists and clinical authors. The large pneumococcus of Löwenberg is still considered as the possible specific organism of the disease. The injections of antitoxin have been found by several observers to be followed by softening and diminution of the crusts, disappearance of odor and increase of fluid nasal secretion. Improvement begins after two or three injections of four to six cubic centimetres. The good results are not always of long duration after the treatment has been stopped, and it is not always free from disagreeable complications.

Gradenigo⁸ has substituted intra-muscular injections of iodine with a similar good result.

TURBINOTOMY AND TURBINECTOMY.

At the recent meeting of the Laryngological Society of London, May 12, 1897, the operation for the complete removal of the lower turbinate for nasal obstruction was discussed. This operation, advocated by Carmalt Jones, with an instrument introduced by him, appropriately called a "spokeshave," has been the subject of discussion and differences of opinion for some time. The instrument is made with the cutting part in a curved form, so as to be convex on the side next the turbinal. Incidentally, the removal of part of the inferior turbinate, either the anterior or posterior end, by means of a snare or punch, was brought up. The general opinion was that the total removal of the bone was a more radical operation than was justified except in rare cases. There is danger of hemorrhage at the time, and secondary, and of drying of the secretions and scabbing as a result of the operation, although in several cases reported this had not occurred. The same subject was discussed at the recent meeting of the British Medical Association in Montreal by the Section on Laryngology. A paper was read for Mr. Jones showing good results, not only in relieving obstruction, but secondarily on the ears. The common criticisms were that it is unnecessarily radical and threatens the subsequent physiological integrity of the nose. The partial turbinectomy was generally sufficient, and even this was to be avoided if space could be gained on the septal side. The discussion was summed up by the President to the effect that complete resection of the lower turbinated bone is almost never called for; that partial removal is only occasionally required and then the anterior portion.

A METHOD OF OPENING AND DRAINING THE ANTRUM.

Following the method now commonly adopted for draining the frontal sinus by opening externally, exploring and draining into the nasal cavity and closing the external wound, Luc⁹ opens the antrum through the canine fossa, investigates the cavity and removes anything that seems advisable, then breaks through into the inferior meatus to establish drainage, and

closes the wound into the mouth by suture. This heals in about three days, and the antrum is washed through the nose as long as is necessary.

MEASLES AS IT APPEARS ON THE BUCCAL MUCOUS MEMBRANE.

Koplic¹⁰ describes an eruption which appears upon the inside of the cheeks at the onset of an attack of measles before the appearance of the skin eruption, which he considers distinctive as a means of diagnosis. Small, irregular spots of a bright-red color are seen on the inside of the lips and cheek, but not on the hard or soft palate; in the centre of each spot is a small bluish-white speck. These spots do not coalesce and do not become opaque white. As the skin eruption appears, the background becomes a diffuse red with a large number of bluish-white specks over it. This appearance soon afterwards fades. In röteln and in influenza the mucous membrane remains normal. In aphthæ the spots are less red, and do not present the bluish-white specks.

RHINITIS SICCA ANTERIOR.

Under this title Ribary¹¹ describes the condition of the mucous membrane covering the part of the cartilaginous septum, which in various stages is shown by dryness, slight scabbing, crust formation, leading sometimes to deeper ulceration and perforation. The normal mucous membrane in this region is covered with ciliated epithelium, which in this disease is converted into pavement epithelium. The surface may appear varnished, and may be traversed by shallow depressions and folds. It is caused originally by picking with the finger-nail, dust, or other irritation. This injured mucous membrane may be a point of invasion for tuberculosis, erysipelas, or other infection. The treatment consists in softening the crusts as often as necessary and covering the surface with an ointment.

AUTOSCOPY.

Kirstein¹² has devised an instrument and technique for the direct examination of the larynx and trachea through the mouth, that is, without the aid of reflecting mirrors. The proceeding is thus simply described by the author: "The patient tilts his head slightly upward and opens his mouth; the physician presses the base of the patient's tongue forward with a spatula." This, however, requires a certain amount of training and skill on the part of the physician, and of tolerance on the part of the patient. A simple autoscope resembles an eulongated tongue depressor which is hooked around the base of the tongue between it and the epiglottis; the head is bent backward and the tongue pressed downward and forward, bringing with it the epiglottis; in this way the posterior wall of the pharynx, the posterior half of the larynx and part of the trachea come within the field of vision. This method the author calls autscopy, and the instrument an autoscope. The field is illuminated either by reflected light or by a special electric attachment. The larynx, especially the posterior half, can then be reached by instruments which are straight and shorter than those in common use, a manifest advantage. He has been able to examine and reach the larynx and trachea in children who are under an anesthetic much more easily and thoroughly than it is possible to do

¹² Monograph, translation by Thorner. F. A. Davis Co.

with previous methods, and occasionally, especially in young children, to dispense altogether with anesthesia.

A somewhat similar method of examining the naso-pharynx is described by Katzenstein,¹⁸ who places the patient on a table with his head bent backward, as in the Rose position. The tongue is grasped and held out, and the soft palate drawn forward with a palate hook. Lindt keeps the patient in a sitting position on a higher level than the observer, and uses a wide hook, concave below, with a notch for the septum. In good subjects the whole vault of the pharynx and the opening of the eustachian tubes can be seen and reached.

TO PREVENT THE DIMMING OF MIRRORS.

Dundas Grant¹⁴ notes a simple method of preventing the dimming of throat mirrors, suggested by Mr. George Wallace. It consists simply in rubbing the glass over with a piece of ordinary dry soap. The film of soap left on the mirror is wiped off by means of a soft rag or handkerchief and it is then found that the mirror can be breathed on without any cloudiness resulting. This is very often needed in cases where direct sunlight or an electric light is used, and means of heating the mirror are not at hand. After washing, the process must, of course, be repeated.

AN EXAMINATION OF THE LARYNX IN INFANTS.

Lack¹⁵ describes a simple method for the examination of the larynx in infants. The child is held in the sitting position, the index finger of the left hand is passed into the mouth and the tip hooked around the hyoid bone, which is pulled forward, the rest of the finger acting as a tongue depressor. The left thumb is pressed under the chin and a small mirror introduced in the usual way. This method is said to cause no pain, no anesthetic is required and it is applicable to every case. In older infants, those with teeth, a curved tongue depressor is used instead of the finger. It is not quite so easy, and some means of opening the mouth may be necessary.

THERAPEUTICS.

Among the numerous applications recommended for different conditions are the following:

Pharyngo-Mycosis. Colin¹⁶ paints the prominent end of each outgrowth with a solution of perchloride of iron, one part to four of water. This stains the fungus, which becomes hard and can be pulled out in two days. This is repeated every second day for three weeks.

Papilloma of the Larynx. Heryng¹⁷ after unsatisfactory results with other caustics uses sulphuric acid of phenol to prevent recurrence after operation, and in certain cases without previous operation. The latter is sufficient for growths on the aryepiglottic folds and cartilages of Santorini. A thirty-per-cent. solution is used, which is rubbed well into the growth.

Phthisis Laryngis. Braunsfeld,¹⁸ following the treatment of Hartman, concludes that the inhalation from solutions of liquo-sulphite reduces the cough and dysphagia, improves the expectoration, and to a certain extent cleans up the ulcerating surfaces; but produces no direct effect upon the tubercular process nor the bacilli. The solution is from ten to thirty per cent.

Cancer of the Naso-pharynx. Kuh¹⁹ reports a case in which a large mass in the naso-pharynx, shown by microscopical examination to be cancer, disappeared under twelve injections of alcohol, of three to thirty minims, after the method of Schwalbe and Halse.

Eucaïne. Lake²⁰ calls attention to a few cases reported by different writers in which troublesome symptoms, such as vertigo, faintness, amblyopia, occurred after the use of eucaïne as a substitute for cocaine; symptoms not unlike those of the latter drug.

THE NOSE AND DYSMENORRHEA.

Fliess²¹ has found such an intimate relation between the nasal mucous membrane and the female generative organs that in some cases he is able to entirely relieve painful menstruation by applying twenty per cent. cocaine to the lower turbinate and the tuberculum septi. These portions of the nasal cavity, he considers, are especially liable to become swollen and seclusive during menstruation.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

JAMES G. MUNFORD, M.D., SECRETARY.

REGULAR Meeting, Monday, March 8, 1897, Dr. C. F. FOLSOM, chairman *pro tem.*, presiding.

Dr. MAURICE H. RICHARDSON read a paper on

ACUTE INFLAMMATION OF THE GALL-BLADDER.

Dr. G. A. RAYMOND, by invitation, read a paper on
THE TREATMENT OF CONGENITAL CLEFT-PALATE BY MECHANISM.¹

Dr. RICHARDSON: I do not feel ready to make any remarks on this subject. I tried once or twice to close the cleft in the soft palate, but never succeeded in doing anything with it. I don't know that I ever tried to close the hard palate. As it appears to me, now, I never shall do the operation, for this obturator method seems a most satisfactory way of treating cases. I think it is perfectly extraordinary how good the voice is in the case of this little girl. Unless I see some reason to change my view, I shall not try to do any surgical work on the hard or the soft palate.

Dr. LANGMAID: I should dislike to let this opportunity go without saying that the conclusion Dr. Richardson has come to I came to years ago, and it has been now eight or ten years since I began to send every one who came to me, in hospital or private practice, to some one who would put in an apparatus. The reader in his paper has referred to Dr. J. M. Warren's operation. I remember one of the difficulties he had, and he was up to all the schemes in that day to close the soft palate over the hard palate. For several days I was engaged in soaking the sutures in compound tincture of benzoin. He thought that so prepared they did not ulcerate. In all these years I have been watching the results of operations upon cleft palate, and I have never seen not only perfect speech but have never seen an approach to good speech. Some years

ago there were brought before one of the societies patients who had had apparatus put in and we heard very perfect speech and singing, and I have taken pains for the past five or six years to see quite a number of patients, had them come to my office, and I have been studying the action of these artificial palates, and I have never seen a case in which the speech was not greatly improved and sometimes made almost perfect. I cannot help thinking that in every way this artificial apparatus must be preferable to any operation involving the cutting away of soft parts, and, as I say, for eight or ten years I have never allowed one of my patients to have an operation done if I could help it.

DR. MIXTER: There is one question I have asked myself several times, and perhaps Dr. Raymond can answer it; it is this: We have appearing at the hospital occasionally these patients with cleft-palate. Now this matter of having an artificial palate applied is one of considerable time and very considerable expense. A certain amount of work has been done, I suppose, at the Dental School, but how much I do not know. I have several times tried my best to get some one to work on these unfortunate patients, who are poor. Some of them come from a distance, have no place to stay and cannot afford to have such an apparatus put in. In several of these cases I have consented against my better judgment to operate, and have done so with a good surgical result, but with anything but a good result as far as articulation went. But what are we to do with these cases which are poor and cannot be fitted with apparatus? Those are the cases where it has seemed to me it was justifiable to do some operation because some men have claimed to get good results. I certainly have never seen anything that approached what you can call a good result as far as articulation goes; but what are we to do with those poor people?

DR. RAYMOND: It is a question I have thought of very much myself, and I have done a certain amount of work along those lines, but I cannot always do it unless I receive some compensation.

About a year ago I took a child who was very poor. She was then twelve years old, a little girl who had never been able to articulate intelligently so that any one could understand what she said. Her mother seemed to understand very well what the child said, but I could not understand her. I wanted to see what I could do for the child. The lip had been operated on by Dr. Bradford at the Children's Hospital when she was very young. I made her an appliance, and a lady in Boston partially compensated me for that work. Of course, it involved much time and was quite an expense to me. The child wore the appliance a while, and I tried to teach her something, but there were many interruptions in the teaching. Sometimes she would not come to take the lesson, so that she failed to get what I desired to give her; and then, a little later, her mother took her away somewhere. One day she left the plate out of her mouth, and about three months later I saw her. In the mean time, owing to the development of the child, changes had occurred in the mouth, so that for my own reputation I had to spend two or three weeks in refitting the appliance to her mouth. She is now wearing it, and I expect to have Miss Jordan try to see what she can do with her. I have been having her come to my house every day, and my wife has been trying to have her put two or three words together to express them.

I have often thought there ought to be some means whereby these children can be cared for, and if they need appliances that the appliances may be made; and then, too, we need a special school for such children. I took this child's case before Mr. Seaver, the Superintendent of Schools, and asked him if there was no school in which she could learn. He asked me if Miss Fuller, of the Horace Mann School, would not take her provided the committee were willing. Miss Fuller said it would be an injustice to the child because the children there are all deaf, and therefore it would not be the place for a child who can hear; so that the child has remained out of school; and, although born in the city of Boston, and thirteen years old, she cannot read and cannot talk so that anybody can understand her. In a few years the child will go out into the world; and what are we going to do with her? We must get her so that she can talk and be understood, so that we can put her in a family where she will earn her living, or else she will bring up in the poorhouse. I think it would be a grand idea for the physicians to interest the public in this question so that there may be some means afforded at the hospitals whereby such a class of children can be helped. I believe there is more hope of the children, and I am putting my efforts in that direction.

DR. HARTWELL: I had a census made of the children in the schools three years ago, to see how many stutters and stammerers there were, because I have found that the doctrine that the muscles were connected with the nerve-centres could not easily be accepted as the basis for work in physical training by the teachers and educators; and I thought I would take some case where we had three sets of co-ordinated neuro-muscular mechanisms, and show what mischief in one or the other might produce. The reports showed that 7 out of every 1,000 school children had some impediment in speech—stuttering or stammering. No distinction was made between stuttering and stammering. I found that the differences between the two sexes and the stuttering rate was correlated with Bowditch's rate of growth. The most scientific man upon this subject was Melville Bell, who pronounced the schools the nurseries for stuttering.

I did not find much in English upon the subject. In looking over the German and the French literature, I came to the conclusion that Kussmaul, a great stutterer, a professor of medicine in Strassburg, had written the best book. One per cent. of the children in Berlin turn out to be stutterers, and there are certain years when the stuttering comes on, the largest number of cases about the first dentition, the next largest about the onset of puberty. Taking the statistics from the lowest to the highest grade, there was very little among the kindergarten children, but the curves ran almost to their maximum in the second and third years of the primary school, where the children were struggling hardest to learn to read; and I can find no reason for believing it is anything more than certain unnatural or mistaken forms of teaching language and reading. I intimated as much in my report.

Some of the teachers of the Normal School were a little chagrined at the idea that their methods might not be the best there ever were, and they wanted to know the views I had on stuttering and how we could help it. I said, I will get some stutterers out of the schools and we will work along and see where we come out. I got some boys, and one of them sent in as a

stammerer had a cleft back into the hard palate. You have heard his speech to-night. We improved those boys a great deal. The method is a recognition of the fact that the voice is a threefold thing, the result of the bellows of the diaphragm, the phonation muscles and articulatory muscles; and we had reason enough to think if we could have them every day instead of once a week we could accomplish something. Dr. Raymond agreed to make this apparatus, and I hope some day we shall be able to give you a record of that boy's improved speech.

DR. SPEAR: I would like to add a few words to the very instructive paper which has interested me on account of the prevalence in ear clinics of these cleft-palate cases, and more especially because I am at present treating a gentleman who has an affection of the ears which undoubtedly resulted from the use of an improperly fitting obturator. I would earnestly call attention to the necessity of examining the ears in all cases of cleft palate in which there is any pathological affection of the post-nasal space or of the turbinate bodies. In my present case the obturator was a very large affair, the cleft being into the bony palate, and the doctor in attempting to close in the space used a very heavy outfit, the wearing of which induced the stasis of blood which produced the disease for which he applied for treatment. The trouble dated from the time he began to wear the obturator and ceased under treatment very shortly after the removal of the same three years later. In this case there was the usual appearance of chronic middle-ear disease accompanying disease of the naso-pharynx and of the nose. The ease with which the Eustachian tube can be seen in these open palate cases make them always of interest to the aurist as they are readily seen without rhinoscopic mirror.

DR. LANGMAID: I was extremely interested in the account Dr. Hartwell gave us of the examination of pupils who stammer or stutter. I suppose every one who sees throat cases is consulted by the parents of children who believe there is some disease of the throat or mouth which prevents their articulating certain consonants, and in fact most of the consonants. On examination nothing is found. The pharynx, larynx and naso-pharynx are normal, and yet this child does not speak so that it is understood except by the parents. Has Dr. Hartwell met with those cases which will not elaborate a consonant? They are not of infrequent occurrence at the hospital and in my office. They are not stammerers. I think there should be special instruction for stammerers and stutterers in our schools, and I would add for this other affection. In these cases, after informing the mother that there is no disease, no malformation, I insist that the child should have instruction either at home or by a teacher. Singularly enough, I have never had them come again with evidences of education. I don't know how they have obeyed my instruction. It is probable that this affection may cure itself. As the child gets older it may make an attempt and the inability may be overcome.

DR. HARTWELL: I think there are many children who have not anything like full power over their vocal organs, but their cases are not recognized or are not reported, and I have never undertaken to recognize how many cases there are. I think those cases would escape the attention of most of our teachers, who have such large classes. My idea is that they need training

in the use of the vocal organs, so that it may be clear that the children can co-ordinate their organs of speech with their hearing, because many of them now cannot, and teachers do not recognize what the trouble is, and they go on with bad habits.

DR. RAYMOND: I might ask Dr. Hartwell whether they made a special band obturator for each case.

DR. HARTWELL: Yes.

DR. RAYMOND: In order to get anything accurate in its contact it would be about as much to do as to fit an obturator attached to a plate that they might get the benefit of at all times. By wearing an obturator the speech is improved; yet if they go without an obturator, the speech, while it may not be quite as bad as originally, it is so nasal and hollow that it is not pleasant to listen to. This child you listened to to-night you cannot get to speak above a whisper if she does not have the appliance in her mouth. During the time she was suffering with tonsillitis and had to keep the plate out of the mouth you could scarcely hear her at all. After she could wear it she would speak in her usual tone of voice.

REGULAR Meeting, Monday, November 1, 1897,
DR. A. L. MASON in the chair.

ANATOMICAL SPECIMENS.

DR. J. C. WARREN: I have two specimens. The first is a specimen of fistula colli congenitalis, a very rare condition about which I had read and of which I had seen pictures, but never had the opportunity of seeing in its perfection before. As represented in the books you find a fistulous opening at the lower part of the neck on the anterior border of the sterno-mastoid muscle about one and a half inches above the clavicle, and this fistula usually reaches from that point to some point in the mouth or pharynx. It is, of course, a branchial cleft which is not closed, and when the end is not open forms what is known as hydrocele of the neck. I have seen tracheal fistulae, small fistulae at the angle of the neck and chin, but never one extending the whole length of the neck, as in this case. The patient stated that a probe passed through the fistula went up to his throat and gave him sore throat on this side. That frightened him, and he decided to have it taken out. I accordingly ten days ago dissected it out. In size and appearance it looked not unlike a rather long appendix. It reached from a point about two inches above the clavicle to the anterior pillar of the tonsil on the left side. When the patient swallowed during the operation this would retract back underneath the chin. It tore off as I was about to cut it off and ligature the end, to be sure there was no opening into the mouth. No opening in the mouth could be found. The wound healed by first intention. This specimen is nicely prepared by the Kaiserling method by Dr. Whitney. My first assistant, Dr. Moscher, has made a drawing taken from the photograph of the patient while under ether and shows the wrinkling of the skin in the act of swallowing. The incision here shows how the fistulous tube passes over the anterior border of the sterno-mastoid and beneath the external jugular vein, which had to be divided and tied.

The other case was one of supposed chronic appendicitis of about a month's standing. I was called into the out-patient department about ten days ago to see

the case, and found a boy with some febrile disturbance and a tumor at McBurney's point. He was recommended to the hospital, and was under my observation several days. In the meanwhile the general symptoms improved. On Saturday I made an incision for operation between the attacks. When I exposed the cecum, I found it was not a case of appendicitis, but of sarcoma of the mesentery at the ileo-cecal flexure. A resection of a portion of the ilium and of the ascending colon together with the appendix was performed. The ends of the bowel were united by the Murphy button and the mesentery sewed up. The disease extended to the root of the mesentery. This specimen shows on one side the interior of the colon and the appendix very much distended and slit open. The operation was done on Saturday. The boy is passing gas to-day and has a temperature about one degree above normal and is in a comfortable condition.¹

ORAL COMMUNICATIONS.

DR. C. H. WILLIAMS: I have a specimen I would like to pass round. It is a section of the entire eyeball from an enucleated eye, that you can see very well under the low magnifying power. The eye was from a boy of seventeen, where there was no history of accident; but he came to me with a considerable amount of pain, no perception of light whatever, and the eye very much inflamed. With the ophthalmoscope a total separation of the retina was found; the other eye was normal. The point about the separation of the retina was that it did not move as the ordinary separation does which has resulted from a serous effusion behind the retina, but remained fast, giving more the appearance of a growth behind the retina. It is impossible to see whether it was a tumor or what it was, but it appeared to be rather a solid mass. On enucleation and section it was found that behind this separated retina there was a large subretinal hemorrhage, which had formed a dense mass in the posterior portion of the eye. It is rather an unusual form of trouble. This preparation is stained with eosine and hematoxylin, and is so thin it can be studied even under high power; it was made by Mr. Robert Osgood, a student at the Harvard Medical School.

DR. FRANCIS S. WATSON read

SOME RECOLLECTIONS OF THE TWELFTH INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.²

DR. F. C. COBB presented a paper on

ACUTE INFLAMMATION OF THE ANTRUM OF HIGHMORE.³

DR. COBB: I should like to show two patients first. One of them has been shown here before, and on transillumination there was absolute darkness on one side.

I think you will see that the light is perfectly clear in one of these patients, and that the other is absolutely dark on one side. This latter is a case of ethmoiditis and antral disease. The first case was an antrum, and after about six months she has become perfectly bright on both sides.

DR. COOLIDGE: I think that this subject of acute infection of the sinuses has not been recognized to the extent that its frequency demands.

The clinical history is often as follows: an acute cold in the nose, lasting a few days, begins to clear up on one side, but the patient notices that the other nostril has a more profuse discharge. After a day or two the patient begins to complain of pain in the face. This pain may be situated about the inner canthus, or in, above or below the orbit, or in the cheek, running down over the teeth. The pain may be intense. The temperature has been very variable in the cases I have followed—in some hardly above normal, in some as high as 104° F. Transillumination shows opacity on the affected side. In many of these cases the antrum is not the only cavity involved, although in some it seems to be. Many of the cases have well-marked edema of the middle turbinate over the whole length; other cases have not. The character of the discharge is muco-purulent, and not the creamy pus seen in the chronic conditions. An exploratory puncture of the antrum is often very simple. An aspirating needle, or better a curved trocar, can be put through the inferior meatus in most cases into the antrum, care being taken that everything is clean; and the antrum washed out. The secretion is very much like that in the last stages of a common cold—muco-purulent—in that way differing from a case of empyema of the antrum due to caries, or other chronic process. My experience has not been great enough to know whether anything is gained by this opening and washing. If not opened the pain disappears in the course of from two to eight days. The unilateral nasal discharge may continue for some days longer. If the process can be shortened, and especially if the pain can be relieved by opening, it should be done. If the pain is in the region of the orbit it is very probably due to a similar condition in other sinuses.

I think that odor and color in the antral discharge indicate opening and washing.

DR. COBB spoke of the condition of the mucous membrane being the cause of the darkness in transillumination in the chronic form. It seems to me in acute inflammation also it is the cause of this darkness, because if you wash out the contents and transilluminate the case immediately afterwards, it is still dark. The light comes back sooner after the cessation of discharge than in a chronic case.

DR. J. P. CLARK: I have very little to add to what Dr. Coolidge has said in the discussion of Dr. Cobb's paper. I believe it is a fact that acute inflammation of the antrum often accompanies acute colds in the head and subsides without special treatment, and that a large proportion of those cases of acute inflammation which do come to a physician get well without opening the antrum simply by keeping the nostrils clear, reducing the swollen turbinates and washing the nose out thoroughly at regular intervals. It is a delicate question to decide as to when one shall make a counter-opening into the antrum, and I don't think it is one about which we can make a rule which shall be generally applicable. Each case must be decided for itself after thoroughly weighing the conditions.

DR. COBB: I have nothing to say in closing the discussion except perhaps a slight point of difference. I think Dr. Coolidge spoke of my using transillumination in chronic cases. These, you will remember, were acute cases I spoke of as being darker and having transilluminated better at the end of a few weeks. In regard to the absence of odor and color as indication

¹ The patient passed the button on the twelfth day and now, on the 21st day, is doing well.

² See page 588 of the Journal.

³ See page 594 of the Journal.

of acute or chronic condition, in all of these three cases the color was very yellow and the discharge very thin and the odor was foul in one of them. With regard to the effect of colds, I happen to have had lately rather an interesting case of a man where a tooth was removed so that the antrum could be washed through that socket, who subsequently to opening the antrum had a very severe bilateral cold. During this cold, on washing out the antrum, he got no more pus from that side than from the other, showing in that case that the cold had not affected the antrum at all.

In this series of cases we are considering, I think transillumination is an infallible sign, because, although difference in the thickness of the bones of the face may make one antrum darker than the other normally, yet if one side is dark and becomes in a few weeks brighter I think the difference in transmission of light is plainly due to the disease. In considering the diagnosis of the presence of pus in the antrum, it is, of course, but a symptom, and only has weight when combined with other signs of empyema.

DR. COOLIDGE: If we transilluminate normal cases we occasionally come to one in which one side lights up well and the other does not. This is due to some anatomical condition. But if we find unilateral pain, purulent discharge and darkness on the same side the darkness is strong presumptive evidence that the antrum is involved.

Recent Literature.

The Medical News Visiting List for 1898. Weekly (dated, for 30 patients); Monthly (undated, for 120 patients per month); Perpetual (undated, for 30 patients weekly per year); and Perpetual (undated, for 60 patients weekly per year). The first three styles contain 32 pages of data and 160 pages of blanks. The 60-patient Perpetual consists of 256 pages of blanks. Each style in one wallet-shaped book, with pocket, pencil and rubber. Thumb-letter Index, 25 cents extra. Philadelphia and New York: Lea Brothers & Co.

This convenient and attractive Visiting List comes in its usual form and usual dress. Those who have used it before will continue to do so, and those who have not would do well to make its acquaintance. The preliminary data have been revised and brought up to date.

A Text-Book of the Diseases of Women. By HENRY J. GARRIGUES, A.M., M.D., Professor of Gynecology and Obstetrics in the New York School of Clinical Medicine, etc. Pp. 728, 335 engravings and colored plates. Philadelphia: W. B. Saunders. 1897.

The first edition of this well-known text-book has already been reviewed in these pages. The second retains the features which have made the first edition a success, and much that is of interest has been added; thus, the changes made by modern asepsis have been introduced into the text, and the descriptions of the operative procedures, which have become popular since the first edition was published, have been appended to the chapters with which they belong. The book is, as before, a strikingly individual one.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 9, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

NICHOLAS IVANOVITCH PIROGOFF.

A FEW days before the opening of the recently held International Medical Congress at Moscow — an event of enormous importance for the future of scientific research along medical and biological lines in Russia — a rather rare occurrence, rare for Russia, took place in the same city, namely, the unveiling of a monument erected by a grateful profession to one of the few scientific and practical workers that Russia can boast of, Nicholas Ivanovitch Pirogoff. The Congress, to judge from the reports of some of the visitors, surprised agreeably not a few of the foreigners, who expected to find Moscow thronged with that somewhat mythical semi-barbaric personage, the Russian moujik (peasant), or the more substantial, although not much less vague, Cossack, and who instead found themselves in a great intellectual centre, not certainly without peculiarities, *suâ generis*, possessing first-rate medical institutions, supplied with all the best and latest scientific requisites and surpassed but by a few in the civilized world. The Congress will doubtless tend to stimulate the desire, excited by the recent achievements of the Russians in the domains of literature and art, to become nearer acquainted with the scientific men of this but little known and less understood nation, which is yet to play an important rôle in the future destinies of Europe.

The conditions of life in modern Russia can hardly be considered as tending to develop a favorable soil for the inception and growth of truly great scientific minds; and if up to now Russia has given to the world but few, comparatively speaking, brilliant scientists, this lack is certainly not to be ascribed to some natural incapacity inherent in the race — for, on the contrary, the Russian is richly endowed by nature — but to certain purely artificial circumstances, which thwart and destroy such minds in their very earliest development.

The survival of one of these is, therefore, the more interesting, as the very fact of his having not only survived on an unfavorable soil, but even achieved great-

ness, speaks volumes for the extraordinary capacity of the man, whose activity in any other land would have been productive of incomparably greater and more lasting benefits to his nation and to the world. Such an exceptional man was, undoubtedly, the great surgeon, N. I. Pirogoff (1810-1881), who, outside of the osteoplastic operation bearing his name, is almost unknown in this country.

In connection with Dr. Watson's account of the Moscow Congress in this same issue of the *JOURNAL*, it seems fitting that our readers should be given a more intimate acquaintance with the career and achievements of one who may be truly considered as the most prominent figure in the history of Russian medicine, his activity forming, as it were, the dividing line between the two sharply defined periods of that history — the ante-Pirogoff and the post-Pirogoff. An implacable enemy of routine tendencies in scientific and practical work, and an ardent supporter of progressive, independent methods of investigation, based on the observation of the phenomena of nature, he was the first to create a school of his own, that is, he succeeded in gathering around him a number of able and enthusiastic men, who, joined together by a unity of scientific methods, continued the labor of their teacher along the lines laid out by him. Thus not only his personal, individual activity, but the impulse given by it to many others, has contributed so much to the advancement of the science of medicine and the art of surgery in Russia.

We can here touch only on some of the prominent events in his life. When hardly twenty-two years old — in 1832 — while defending his thesis for the degree of Doctor of Medicine ("Treatment of Aneurism of the Iliac Artery"), on which he spent more than three years, Pirogoff promulgated the theory—a rather bold step in those times—that the solution of various medical problems requires not only clinical observation, but experimentation on animals as well; in fact, the experimental is sometimes the only way through which we can reach the solution of a clinical problem.

Working along the same experimental lines on the problem of ligating bleeding vessels, he reached the conclusion that a temporary ligature of a bleeding artery can only be practicable when its inner and middle coats are divided, thus curling themselves up when the ligature is fastened. This gave him an impulse in the direction of the anatomical study of the subject, the results of which were embodied in an anatomical work of a classical character, which at once created for the author a prominent place among the anatomists of the period. It is said that when Pirogoff, who was then twenty-eight years old, came to Paris with the purpose of studying there under Velpeau, he, on visiting Velpeau, found him engaged in diligently scanning the anatomical plates annexed to his (Pirogoff's) work. "It is I who must take lessons of you, and not you of me!" Velpeau exclaimed, with the impulsiveness of his French nature.

Pirogoff was one of the very few who foreshadowed

the advent of antiseptic surgery and the teachings of modern bacteriology, inasmuch as he taught that the infection in pyemia was due to the influence of some special ferments admitted from the atmosphere or developed within the blood. This view contrasts strongly with the theories held by many of his contemporaries.

In 1840 he issued a notable work on tenotomy of the tendo-Achillis for talipes. Some four years previous to this, Pirogoff was the first to perform this operation in Russia—a rare event even for Europe of that period, when the operation was done only by Stromeyer, the originator of subcutaneous tenotomy, and one or two other surgeons. Before the publication of his work Pirogoff had done some forty tenotomies. His subsequent studies on the process of repair after the division of the tendons are full of interest even for the modern surgeon.

Nicholas Ivanovitch Pirogoff.

The ligation of the lingual artery in cases of hemorrhages following wounds of that artery, most frequently as a preliminary step in the removal of the tongue, was first done by Pirogoff in the second part of its course, in 1836.¹

He was the first surgeon in Russia to apply ether as an anesthetic; as a true scientist, he first experimented with the newly invented agent on animals, on healthy men and even on himself. Being sent to the theatre of military activity in Caucasus in July, 1847, he resorted extensively to the employment of ether on the battleground. He was also the first to introduce into his military practice the use of the immovable bandage (gypsum) applied around extremities shattered by bullets, and in compound fractures. It was also at this time that he performed the operation bearing his name, which, as originally done and with some subsequent modifications, shares the honors with that of Syme.

It was particularly during the Crimean War that the all-embracing activity of this man found an almost unbounded field for labor. The enormous mass of ma-

¹ *Operative Surgery*, F. Treves, vol. i, p. 165.

terial gathered at this and at the previous war served as a framework for his "Grundzüge der Allgemeiner Kriegschirurgie," a great work which was, even up to a very recent date, recognized as a classical contribution to the literature of the subject. During his service as a military surgeon he introduced so many reforms, not only in the purely medical part of his department, but in the administrative side of the same, that he incurred the enmity of the higher military administration at Sebastopol, which resulted in his compulsory resignation from the professorship at the St. Petersburg Military Medical Academy. However, this was not the first time he suffered at the hands and from the stupidity of the high authorities. When in 1840 he was called to St. Petersburg from Dorpat (where he occupied the chair of surgery), his attempts to improve the sanitary condition of the Military Hospital connected with the Academy met with such opposition and created so much ill-feeling between him and the authorities that he was for a time considered insane and closely watched by secret detectives.

Pirogoff was also a very prominent educator. The appearance of a work of his on education, namely, "Vital Questions," produced a deep impression on the intelligent portion of the Russian community, and led in the course of time to his being appointed Superintendent of the Odessa, and later of the Kieff Department of Education. In the first, he was instrumental in laying the foundations for a university, an undertaking of the difficulties of which in Russia no foreigner can form an adequate conception.

His professional activity was so closely connected with his scientific and practical work as to become inseparable from it. He raised the standard of studies and laboratory work to a position they never occupied before, and many of the institutions attached to the Academy are indebted for their existence to his efforts. It may be of interest to note what he said several years before his death on a public occasion, about the method of teaching practised during his student years. According to this, he passed his examination at the university (at Moscow) without having seen or performed one single operation on the cadaver; nor was this condition much better in the western European universities. While he was in Germany, it was of frequent occurrence to hear prominent professors expostulating on the futility of anatomical knowledge for a surgeon: "You will hardly believe me, when I say that their method of finding one or another arterial trunk was based entirely on their sense of touch; feel of the pulsating artery and tie everything from which blood issues."

Pirogoff's clientele included people from all walks of life, and from every corner of the vast empire, and he was honored with a respect which only an hero-worshipping people, like the Russians, are capable of bestowing upon one of their great men. We conclude with the three inscriptions on his monument, which thoroughly characterize the man.

"Even when desiring to become thorough special-

ists, we must never forget that we need a general humanitarian education."

"I made it a rule on my first accepting the chair in the University never to hide anything from my students, and if not at once, then later on without hesitation to uncover before them any mistake I might have committed in the diagnosis or treatment of the disease."

"It is impossible to separate in the University the educational from the scientific. But the scientific without the educational shines and warms (is both useful and ornamental), while the educational without the scientific, however attractive its appearance, can only shine."

A FORTY YEARS' SUMMARY OF THE VITAL STATISTICS OF MASSACHUSETTS.

DR. S. W. ABBOTT, the accomplished secretary of the Massachusetts State Board of Health, has summarized for the Twenty-eighth Annual Report of the Board the essential facts relating to 630,680 marriages, 1,780,872 births, 1,317,453 deaths and 56,005 stillbirths recorded in the State from 1856 to 1895.

The population of the State has more than doubled in that time, the increase from the census of 1855 (1,132,369) to that of 1895 (2,500,183) having been 1,367,804, of which two-thirds consisted of immigrants from other States and countries. Emigration from the State, mostly to Western States, is indicated in part at least by the proportion of marriageable males to marriageable females, 277,180 to 370,973 (by the census of 1885).

In spite of the large influx of foreigners, among whom there is a greater ratio of persons of child-bearing ages and a higher birth-rate than among the native population, the general marriage-rate and birth-rate have diminished.

The total recorded death-rate has not materially diminished, having been in the four decades, respectively, 19.36, 19.59, 19.35 and 19.63. But increased accuracy and completeness of registration in the later years mean really a greater mortality than was reported when the records were more imperfect. The density of population too had increased from 136 per square mile in 1855 to 300 per square mile in 1895—a fact that may be taken to show that improved sanitary conditions have very nearly counterbalanced the unfavorable influence of increasing density.

The infantile death-rate of the first twenty years was 150.3 and that of the second twenty years was 161.2 per 1,000 births. The difference in the rates of the ten-year periods is much greater, chiefly on account of the disturbing effect of the epidemic years 1872 and 1873. The infantile death-rates of the four ten-year periods were, respectively, 134.2, 164.2, 157.8, 163.6. By this it appears that the infantile death-rate has increased considerably, when we compare the first twenty years with the last twenty, and especially when the first and last ten years are compared. If the figures for the two years 1872 and

1873 were to be omitted from the table, the infantile death-rate of the remaining eight years in the ten-year period 1866-75 would be reduced to 156.5.

The death-rate of infants under one has diminished with considerable uniformity during the last five years (1891-95) from 169.0 per 1,000 births in 1891 to 158.2 in 1895.

The death-rate of infants of the State at large was 160 per 1,000 births, while that of the combined urban population was 175 per 1,000 and that of the rural population was 129.

The probability that an infant under one year old will complete its first year of life is less at the present day than it was in the first half of the period, but, having survived his first year of life, his chance of completing the next four years is considerably greater than it then was.

The decrease in the death-rates from the infectious diseases is great and very gratifying, especially from typhoid fever, in which the lessened mortality corresponds directly with the introduction of pure drinking-water, and from scarlet fever.

There was, comparing the two twenty-year periods, a slight decrease in the death-rate from cholera infantum, a very great decrease in that of dysentery (5.11 to 1.55), a slight decrease in that of diarrhea (2.57 to 2.46), a considerable decrease in that of cholera morbus (0.70 to 0.43), and a marked increase in that of enteritis (2.01 to 3.23). There was, therefore, an improvement of 2.77 per 10,000 of the population in the total of these diseases.

The whole number of deaths registered from consumption in the forty years 1856-95 was 209,115, and the mean death-rate of the whole period from this cause was 30.9 per 10,000 living; 96,278 occurred in the first twenty years and 112,837 in the last twenty, the mean death-rate of each period being, respectively, 35.7 and 27.8 per 10,000. The maximum death-rate in any year from this cause was that of the first year, 1856, and was 40.8 per 10,000, and the minimum (21.9) was that of the last year, 1895, so that the death-rate from consumption had declined nearly one-half in the whole period of forty years.

The mortality from pneumonia has increased in the forty years. The death-rate per 10,000 living of the first twenty years was 12.2; of the second, 16.8; and of the eight five-year periods respectively 9.6, 11.9, 11.8, 14.7, 14.2, 16.0, 16.4 and 19.7.

From kidney diseases, heart diseases, brain diseases and cancer there has been a marked increase in the mortality, a certain portion of which must be attributed to more accurate registration.

In the mortality from the diseases and incidents of child-birth are included all deaths classed as from child-birth (all deaths specified as from abortion, child-birth, miscarriage and puerperal convulsions), puerperal fever, metritis, metria, puerperal septicemia and the excess of female deaths from septicemia over those of males. The whole number of cases of birth in the forty years was 1,820,756, and the deaths by child-

birth, etc., 12,075, or 66.3 per 10,000. In the first period (1856-75), with 745,461 cases of birth, there were 5,584 deaths in child-birth, or 74.9 per 10,000, and in the second period (1876-95) 1,075,295 cases of birth produced 6,491 deaths, or 60.4 per 10,000. The death-rates by five-year periods were as follows: 68.6, 68.1, 76.2, 83.8, 73.3, 72.9, 54.4, 48.2. There was an increase up to the fourth period, and then a greater decrease to the close.

The great epidemic of cerebro-spinal meningitis in 1873 caused 747 deaths, and in the year of the next greatest prevalence, 1888, 171 deaths were from it; the minimum number of deaths, 78, was in 1878.

The whole number of deaths registered as due to influenza from 1856 to 1875 was 943, and the mean annual death-rate per 10,000 from this cause was 0.35. From 1876 to 1895 the deaths were 3,372, and the mean annual death-rate 0.83 per 10,000. In no year of the first period did the deaths attributed to this cause exceed 92 (1857), and in no year of the second period previous to 1890 did they exceed 48, but in 1890 they suddenly rose from 27 to 411, and in the six closing years of the period they were, respectively, 411, 546, 967, 296, 370 and 457, the deaths from this cause in these six years constituting more than 90 per cent. of all the recorded deaths from the same cause in the twenty-year period, 1876-95.

The striking increase in malarial diseases shows itself to only a slight extent in the death-rates.

While the death-rate for the forty years has remained nearly uniform, the factors which compose it have varied in a remarkable degree. Certain causes of death or general groups of causes have diminished notably in their incidence upon the population, while others have quite as notably increased. Infectious diseases generally, including consumption, have diminished, while most of the so-called local diseases (those of the nervous, respiratory, circulatory organs, etc.) have increased, and the result has been a balance or a maintenance of uniformity in the general death-rate. These changes also affect the death-rates at different ages, since the diminishing causes of death (the infectious diseases) are mainly diseases of childhood and early life, while the increasing causes are chiefly those of advancing age, and the general effect would be the prolonging of the life of the population.

MEDICAL NOTES.

THE TENNESSEE MEDICAL COLLEGE at Knoxville, Tenn., was destroyed by fire on December 3d.

DR. CURTIUS TO SUCCEED PROFESSOR MEYER.—Dr. Th. Curtius, professor of chemistry at Bonn, has been called to Heidelberg as successor to Victor Meyer.

FOREIGN MEDICAL STUDENTS IN PARIS.—It is stated that the decree excluding foreign students from the medical classes of the Faculty of Medicine of Paris will shortly be withdrawn.

A VETERAN. — Lawrence McCarthy, said to be the last survivor of the combatants at Waterloo, died late in November in the workhouse at Nenagh, Tipperary, Ire., aged one hundred and fifteen years. He is said to have been born in Nenagh early in 1782 and to have attained his thirty-third year when he fought at Waterloo, where he was severely wounded.

INTESTINAL WORMS IN CHINA. — It is stated that ninety-five per cent. of the children in Pekin suffer from thread worms. Their frequency is supposed to be due to the ingestion of water and raw vegetables from the Chinese equivalent of sewage-farms. Europeans, who habitually boil or filter their drinking-water and cook their vegetables, are comparatively free from the parasite.

THE PIROGOFF MUSEUM. — The Pirogoff Museum of Surgery and Anatomy, in St. Petersburg, was opened at the beginning of the present month. The building will serve not only as a museum, but also as the place of meeting of all the St. Petersburg medical societies. The \$30,000 bequeathed for the purpose by Mme. Musin-Pushkin has been doubled by subscriptions, and some endowment remains after the cost of the building has been defrayed.

"THE PHILADELPHIA MEDICAL JOURNAL." — In January, 1898, the Philadelphia Medical Publishing Company, incorporated under the laws of Pennsylvania, proposes to begin the publication of a weekly medical journal, with the above title. The management of the company is entrusted to a board of trustees in which are representatives of the leading medical schools of Philadelphia. Dr. George M. Gould will be in charge of the editorial management.

THE FIFTH AVENUE WATER PIPES AS A SEWER. — The *Medical Times* of New York City calls the attention of the health board to the fact that the large water pipes which are being laid in Fifth Avenue have been used by the Italian workmen as a urinal, if not worse, during the protracted time during which this work has been in progress. The editor says that he has watched the workmen from his sanctum window and knows whereof he writes.

THE HEALTH OF BRITISH TROOPS ON THE INDIAN FRONTIER. — The *British Medical Journal* calls attention to the abnormal amount of sickness reported among the British troops in the Tochi Valley, and suggests that the unfortunate falling off in stamina and endurance there exhibited may not be due entirely to the hardships of the campaign but on investigation "may point to evils which the Contagious Diseases Act was intended to prevent as the *fons et origo* of the lamentable decline in vigor of the unfortunate victims of a fatuous policy."

MEDICAL VICTIMS OF YELLOW FEVER. — The outbreak of yellow fever in New Orleans, as elsewhere, is over. The *New Orleans Medical Journal* reports three additional cases among the medical profession in that city. Drs. A. C. King, A. R. Choppin

and E. B. Viers, making a total of over a dozen. A death must, at the same time, be reported, that of Dr. E. B. Viers, making a total of two for the whole period. About the same number of trained nurses, as of physicians, were stricken with the disease, but without fatality. The two physicians who succumbed to the disease were young men, unacclimated, and who had lived in New Orleans only a short time.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, December 1, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 58, scarlatina 33, measles 16, typhoid fever 9. For week ending December 8th, the following cases were reported: diphtheria 55, scarlatina 23, typhoid fever 8, measles 4.

DEATH OF A CENTENARIAN. — Miss Susan Wesson died recently at her home, in Roxbury, at the age of one hundred years.

THE CARNEY HOSPITAL LOSES A BEQUEST. — In the Massachusetts Supreme Court, Judge Allen recently reversed the decree of the Probate Court and disallowed the will of the late Michael Curley of Brighton, who left his estate in equal parts to Rev. Father Francis J. Butler of Brighton, who was made executor, and the Carney Hospital. The amount to be divided between the two would be about \$15,000. The will was disallowed for the reason that the testator was adjudged to have been of unsound mind at the time it was made.

ENDOWMENT OF A HOSPITAL FOR DOVER, N. H. — By the will of the late Mrs. Claragusta L. Hayes of Dover, N. H., after several bequests to relatives, the remainder of the estate, which is estimated at \$50,000, is given for a hospital for the inhabitants of Dover, to be known as the Hayes Hospital.

GRADUATION AT THE DARTMOUTH MEDICAL COLLEGE. — The one-hundredth graduating exercises of the Dartmouth Medical College occurred in the college church in Hanover, N. H., on November 23d. President Tucker presided and Dr. Charles A. Morse delivered the address to the class. Twelve men received their medical degrees.

NEW YORK.

ISOLATION OF CONSUMPTIVES. — As a practical result of the Board of Health's long-continued efforts to curtail the ravages of tuberculosis, the Board of Estimate and Apportionment, at a meeting held December 2d, decided, after a brief discussion, to appropriate the sum of \$60,000 to enable the Health Department to send poor patients suffering from the disease to an isolated hospital. President Wilson and Dr. H. M. Biggs appeared at the meeting as the representatives of the Board of Health. The former stated that it was in 1893 that the Department first agitated the subject of the isolation of consumptive patients. The idea was at first not well received, and in the first year only 216

cases of the disease were reported. But as the matter became better understood the physicians and the hospitals became interested, and this year 1,740 cases were reported by physicians and 7,948 by hospitals and public institutions, and the Board of Health was enabled to map out the habitat of the disease. Now, he argued, if the city could be induced to lend assistance the Board would be able to take many cases out of places where they were a menace to the public health and place them where they would receive enlightened treatment and where in many instances cures could be effected.

Dr. Biggs said that most of the private hospitals now refuse to accept consumptive patients, and about forty were turned away each week. If the Board of Health were given the opportunity, patients might be taken away from their homes in suitable cases, and grave sources of contamination would thus be done away with. One-fourth of all the deaths among working people was due to tuberculosis. "There is no question," he continued, "about the possibility of stamping out the disease. Any contagious or infectious disease can be stamped out."

The resolution passed by the Board of Estimate authorizes the Health Department to send tuberculous patients to any desired hospital, but the latter has selected Seton Hospital as the most suitable for the purpose. It is finely situated, in an isolated position, on Fordham Heights, near Spuytenduyvil, and is one of the best constructed and equipped hospitals in the country. It was erected in 1894 and was especially designed for the treatment of tuberculosis. When opened it had a ward capacity of 120, beside accommodation in private apartments; but this can be extended indefinitely, as occasion may require. It is understood that no patient will be forced to go there, but all the poor affected with this disease can avail themselves, if they wish, of the opportunity thus afforded for isolation, pure air and the best scientific treatment.

THE EXPENSES OF THE HEALTH DEPARTMENT. — The Board of Health's budget for 1898, amounting to \$503,077, has been passed, but this appropriation will necessarily have to be revised by the new Board of Estimate of the Greater New York. If it is allowed to stand it will be for the year's expenses of the Health Departments of the Boroughs of Manhattan and the Bronx.

TYPHOID FEVER AND MILK. — Health Inspector Leale, of Paterson, N. J., has successfully traced the origin of a recent outbreak of typhoid fever in that city. There have been about thirty cases of the disease already reported, but up to this time no deaths. It was ascertained that the milk used by the families of the affected was supplied from a dairy at Branchville, Sussex County, and that the water in which the milk cans were washed was procured from a contaminated brook, the source of the contamination being three cases of typhoid in the family of the proprietor of the dairy. More than a dozen cases of typhoid

which were reported within three days in Kearney township are also believed to have originated from the same source. It was found that all the families in which cases had occurred were supplied with milk by a dealer who obtained his supply, in part at least, from the Sussex County dairy.

DIPHTHERIA WITHOUT ANTITOXIN. — Within ten days a mechanic of Elizabeth, N. J., lost his wife and five out of six children, from diphtheria. When the first child was taken ill the mother thought the trouble was only an ordinary cold and sore throat, and when medical aid was at last summoned antitoxin was refused.

DEATH OF DR. GILCHRIST. — Dr. William N. Gilchrist, well known among the older physicians of New York, died at the Windsor Hotel on December 3d, after a long illness. He was seventy-four years of age, and was born in Kortright, Delaware County, New York. He was a graduate of the Vermont Medical College, and came to New York in 1847. He took up his residence at the Windsor Hotel when it was first opened in 1873, and practised there until three years ago, when his wife died and his health began to fail.

DEATH OF DR. JAMES OLMSTEAD. — Dr. James Olmstead, of New Haven, died at the Hotel Grenoble, New York, on December 4th. He was born in New Haven in 1849, and was a graduate of Yale College and the Yale Medical School. In 1877 he received an appointment at the Connecticut Hospital for the Insane, of which he became superintendent in 1886.

Miscellany.

PRESIDENT McKINLEY RECOMMENDS A COMMISSION FOR THE INVESTIGATION OF YELLOW FEVER.

THE President of the United States, in his message to Congress, refers to the recent outbreak of yellow fever in the Southern States, and recommends the appointment of a commission of experts in the following terms:

The recent prevalence of yellow fever in a number of cities and towns throughout the South has resulted in much disturbance of commerce, and demonstrated the necessity of such amendments to our quarantine laws as will make the regulations of the national quarantine authorities paramount.

The Secretary of the Treasury, in the portion of his report relating to the operation of the Marine-Hospital Service, calls attention to the defects in the present quarantine laws, and recommends amendments thereto which will give the Treasury Department the requisite authority to prevent the invasion of epidemics from foreign countries and in times of emergency like that of the past summer will add to the efficiency of the sanitary measures for the protection of the people and at the same time prevent unnecessary restriction of commerce.

I concur in his recommendation of further effort to prevent the invasion of the United States by yellow fever. The importance of the discovery of the exact cause of the disease, which up to the present time has been undetermined, is obvious, and to this end a systematic bacteriological investigation should be made.

I, therefore, recommend that Congress authorize the appointment of a commission by the President to consist of four expert bacteriologists, one to be selected from the medical officers of the Marine-Hospital Service, one to be appointed from civil life, one to be detailed from the medical officers of the Army, and one from the medical officers of the Navy.

THE INJURIES IN MODERN NAVAL WARFARE.

FROM the report on the wounded in the naval battles between Japan and China, presented at the International Medical Congress, at Moscow, by S. Suzuki, M.R.C.S. Eng., L.R.C.P. Lond., Fleet Surgeon of the Imperial Japanese Navy, we are able to obtain for the first time in the history of naval warfare an adequate idea of the physical effects upon the combatants of sea fighting under the modern conditions of the opposition of powerful armament to massive armor.

The naval conflict of the Yalu was the first in history in which these conditions were exemplified, and although from the recently published personal experiences of Commander McGiffen, who fought so valiantly in command of a Chinese ship in that conflict, we gained some idea of the fearful effects of concussion, splintering of iron and wood by shell explosions, etc., which, as is well known, ended in his own case in insanity and suicide, the carefully compiled reports of Fleet-Surgeon Suzuki give us the first careful statistical information on the subject.

Of the 298 men killed or injured in the battle of the Yalu, a greater number suffered injuries to the head than any other part of the body. The injuries to the greater part of the body naturally caused the largest percentage of deaths, for the reason that a large number of them consisted of burns covering an area of more than one-third of the body. Only two out of 57 cases of this class recovered. Wounds to the abdomen and lumbar region were very fatal, because, unlike the simple punctures of rifle bullets, these consisted for the most part of fearful lacerations of the body and contained viscera by fragments of shell.

On comparing the number of wounds received in a land battle with those of a sea fight between opposing forces of equal numerical strength, Suzuki finds that the number of wounds is almost identical, but that while in naval battles wounds of the head, in land battles wounds of the extremities, predominate. Suzuki explains this by the fact that bullets and shells, the chief causes of injuries in fighting on land, are more apt to hit the extremities, while in sea fights the flying splinters of steel and wood from shattered armor, planking and rigging are more apt to hit the heads of the combatants. As an example of the damage from flying splinters, it is related that the funnel of the *Fuso* having been perforated by a shell, the fragments of it were dispersed around and either killed or injured ten seamen.

The antiseptic treatment of the wounds received in battle was carried out with excellent results in the saving of life and limb. No infectious diseases of wounds occurred except one fatal case of erysipelas.

The sanitary condition of the navy during the war was excellent, and the average body weight of the force actually increased during its continuance. Venereal diseases were the cause of 37.69 per cent. of the cases of illness occurring during the war. Forty-three

cases of beri-beri and only three cases of cholera occurred in the navy. The total number dying at sea during the war was 227, of whom 150 were killed and 177 died of disease.

The report, which has recently been published in attractive pamphlet form, gives many details of great interest, and will well repay perusal. The author is to be congratulated upon the success and thoroughness of his work, both as a surgeon and a statistician.

SURGERY ON THE BATTLEFIELD WITHOUT ANESTHESIA.

"It was here that I performed my first big operation, the patient being a Turkish infantryman who was brought in from Alexinatz with his knee shattered by a shell. He refused to take chloroform, and I took his leg off above the knee without any anesthetic. He never said a word and went on smoking a cigarette all the time. When the captain came round with his note-book afterwards, to take down the name, age and regiment of each wounded man, my patient answered all the questions quietly and unconcernedly while I was stitching up the flap of skin over the stump. It was a marvellous exhibition of fortitude."

The above passage is taken from a book by Charles S. Ryan, an Australian, lately published by John Murray, London, in which the author relates his experiences as an army surgeon in the Turkish service during the campaign around Plevna in 1877. Many other instances of Turkish fortitude and of other virtues are given. The narrative is as thrilling as a Stanley Weyman or an Anthony Hope story, and, withal, impresses the reader with the feeling that the incidents occurred as they are described.

DR. HARRISON ALLEN.

RESOLUTIONS OF THE PHILADELPHIA NEUROLOGICAL SOCIETY.

At a meeting of the Philadelphia Neurological Society, held on the 22d of November, the following action was taken:

Whereas, the Philadelphia Neurological Society has heard with great regret of the death of Dr. Harrison Allen, it desires to offer its sympathy to his family and to give expression to its sense of the great loss which has been sustained by science and the medical profession.

Dr. Allen was deeply interested in neurology, not only as a human and comparative anatomist, but also in various practical directions, as indicated by his valuable contributions to this society and other medical bodies.

CHARLES W. BURR, *President*.
WM. G. SPILLER, *Secretary*.

Correspondence.

[Special Correspondence.]

PUBLIC HEALTH IN LONDON.

LONDON, November, 1897.

MR. EDITOR:—London is so vast, geographically, and is composed of so many practically distinct townships or parishes, that it is almost impossible to obtain any idea of the city as a whole. It has, for instance, no one public health department. There are forty-one separate medical health officers, each one appointing his own clerks and inspectors, and each one answerable only to his own vestry.

To be sure, all must conform, in important particulars, to the provisions of the London Public Health Act of 1891, and all must submit, in certain cases, to the supervision of the London County Council, through its medical officer. There is no uniformity, however, as to the details of the work. The law provides, for instance, that every house must be disinfected after each case of infectious disease, but does not prescribe the method of such disinfection. The result is that one medical officer may still cling to old and obsolete methods, while his neighbor, across the street, may work in a new and absolutely scientific manner. Again, such a short street as Drury Lane may, and, as a matter of fact, does, belong to three separate and distinct parishes. No power on earth can prevent each particular parish from paving its own part of the street according to its own fancy.

I have said that the medical officer of the London County Council was able to exercise a certain amount of supervision over the various local health physicians. This is true, but he must be extremely careful in his interference, and absolutely certain of his ground, because he must antagonize not only the local health-officer, but also the vestry of the district. The present incumbent, Dr. Shirley F. Murphy, manages affairs with rare tact, and is gradually introducing uniform methods throughout the city. English conservatism, however, prevents any rapid progress.

Of extreme interest are the charts and tables prepared by Dr. Murphy during the last few years, and especially so are those relating to infectious diseases among children. He has followed, unconsciously, the exact lines taken by Dr. McCollom in our own city, and has arrived at a precisely similar result. His charts, prepared independently, are almost exactly like those of Dr. McCollom, and he finds the great increase in cases notified at the same time of the year, namely, about a month after the holidays. He also made investigations as to the ages of the patients, and found that the school-children were principally attacked; and as the period of incubation had more than elapsed each half-year before the great rise, he concluded that many of the cases were contracted not at the homes but at the schools. After publishing his report, he was answered by several health-officers of surrounding places, who said that while his conclusions might be true of a large city like London, they would not necessarily follow in smaller communities. He then took the figures which had been furnished him from year to year by these very opponents, and proved to them that the same thing obtained in their several towns. Such a complete verification of our own city physician's investigations and conclusions was exceedingly gratifying.

Perhaps the most interesting thing in public-health work in London to-day is the plant at St. Leonard's, Shoreditch, for the destruction of garbage (or "dust" as it is here called) by burning, and the subsequent utilization of the power thus obtained for the electric lighting of the parish. Shoreditch is one of the most densely populated of the London districts. It covers about one square mile, and contains about 120,000 people. The furnaces, engines and dynamos are located in the middle of the parish, and yet not one complaint has been made. Remember, too, that an Englishman is not prone to submit to a nuisance without growingl.

Before the commencement of this summer the parish of St. Leonard's paid 3s. 2d. per ton to bargemen to barge away its refuse and throw it into the sea. The present works were experimentally started some time in May last, and formally opened by Lord Kelvin about the first of July. They have thus been running about five months, and it seems as if, now, a fair idea might be obtained of their value.

The dust bins of London contain all sorts of household refuse, from decayed meats and vegetables to empty, broken bottles. The dust is collected at regular and frequent intervals, and carried in the parish carts to the electric-light station. Here it is dumped into an immense iron car which is divided into five distinct sections. After the car has been filled it is hoisted by means of electricity to the top of the furnaces and is then run along a track by means of a trolley until it is over the particular fire which it is intended to

feed. The top of the furnace is then opened from above, by means of a sliding door, and one of the sections of the car is emptied into it. The refuse falls on the back of the fire, quickly parts with its moisture, and is then pulled over the fires by means of rakes handled from below. Three large fans are used to send a continual blast through the furnaces. Two of these collect air from the upper part of the furnace house, so that any noxious fumes arising may be destroyed, and the third ventilates the sewer running under the building. Such a method of sewer ventilation would be very valuable were it not so exceedingly limited in its application. It can only be of value, unfortunately, as far as the nearest sewer opening.

The slag, accumulating in the furnaces, is being constantly removed to the yard, and the finer particles, falling through the grates, are also removed, but placed in separate heaps. The finer residue is bought by builders, and used in the manufacture of fireproof cement. The larger pieces, consisting of about 30 per cent. of the total refuse dumped into the furnaces, are at present carted away. Successful efforts are, however, being made to manufacture artificial stone from them for pavements, steps and floorings. I saw some very fine specimens of this stone already in use, but its employment in this way is hardly as yet economical enough to be practical.

The contractors agreed to furnish 120,000 tons of steam per annum from an equal amount of dust. They have done somewhat better than this. At present they furnish steam enough to run all the dynamos for the electric lighting of the parish, using from 200 to 850 horse-power, according to necessity. At the time that I saw the plant, only ten tons of coal had been needed in the preceding month as auxiliary fuel. Of course, we must reckon that the dust bins contain more or less partly-consumed coal, provided by careless housemaids.

In his opening address, Lord Kelvin mentioned one thing which should not be omitted in the consideration of the general economy of the undertaking. He said: "A very important novelty is Dr. Hapin's heat-storage system, in virtue of which part of the steam raised will be used to meet the daily demand, and part laid up in store. That store is a cylinder of water, ready to feed the steam engines when night comes on and a greater supply is wanted. Thus the engines will get water into their boilers ready heated up to their full temperature and pressure, and only the heat of evaporation will have to be supplied by the combustion of the dust during the lighting hours."

A thermal vessel which would stir up energy for use at a later period would of course be an immense desideratum in the production of power. In point of fact, however, this vessel has not been as yet used. It was poorly made, and leaks at the rivet holes. Besides, it is not of such great practical value in London as it would be in other cities, because the prevailing fogs of winter require full pressure most of the time. I must confess that I am a bit sceptical as to its ultimate employment, since the radiation from such a huge vessel must be very great, and the preservation of heat must consequently be exceedingly difficult. The Vestry of Shoreditch are now building a large public swimming bath next to the electric-light station, and intend heating their water through pipes connected with the present furnaces.

At this time, when the problem of the disposal of garbage is being discussed in all our large cities, it would seem that a system which not only destroys without offence but utilizes the destruction for such a practical town purpose as electric lighting should meet with some consideration. There is, at least, no odor apparent, and no nuisance created in the neighborhood. I climbed to the tops of the furnaces, and went along the upper part of the building, and detected nothing unpleasant except the inevitable dirt arising from the dumping of the cars. It has certainly, so far, done its work, and, although the initial cost must have been great, the Vestry of Shoreditch seem perfectly satisfied as to its ultimate economy.

Very truly yours,
WM. G. MACDONALD, M.D.

METEOROLOGICAL RECORD

For the week ending November 27th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,225; under five years of age 625; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 234, acute lung diseases 331, consumption 271, diphtheria and croup 98, typhoid fever 35, diarrheal diseases 31, measles 20, scarlet fever 16, cerebro spinal meningitis 14, whooping-cough 8, erysipelas and malarial fever 6 each.

From measles New York 11, Pittsburg 6, Brooklyn 2, Baltimore 1. From scarlet fever New York 6, St. Louis 3, Brooklyn 2, Baltimore, Boston, Cincinnati, Washington and Waltham 1 each. From cerebro-spinal meningitis New York and Brooklyn 3 each; Worcester and Somerville 2 each; Boston, Providence, Lynn and Chelsea 1 each. From whooping-cough Brooklyn 4, New York 2, Boston and Cincinnati 1 each. From erysipelas New York and St. Louis 2 each, Newton and

Everett 1 each. From malarial fever New York, Brooklyn and Nashville 2 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending November 20th, the death-rate was 18.6. Deaths reported 3,927; measles 159, fever 67, diphtheria 64, whooping-cough 63, diarrhea 52, small-pox (Bristol) 1.

The death-rates ranged from 11.3 in Bradford to 24.7 in Leeds; Birmingham 20.1, Cardiff 14.4, Gateshead 19.6, Huddersfield 15.4, Leicester 17.7, Liverpool 24.3, London 18.9, Manchester 21.0, Newcastle-on-Tyne 18.0, Nottingham 17.9, Portsmouth 13.4, Sheffield 16.7, Sunderland 21.3.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 26, 1897, TO DECEMBER 3, 1897.

MAJOR JOSEPH K. CORSON, surgeon, having served more than thirty years in the Army, is on his own application by direction of the President retired from active service this date, November 30, 1897.

FIRST-LIEUT. BASIL H. DUTCHER, assistant surgeon, is relieved from duty at Fort Leavenworth, Kansas, and ordered to Fort Grant, Arizona, for duty at that station.

Leave of absence for three months to take effect December 1, 1897, is granted CAPTAIN NORTON STRONG, assistant surgeon.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING DECEMBER 4, 1897.

S. S. WHITE, passed assistant surgeon, detached from the "Concord" and ordered to the "Wheeling."

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, December 13th, at 8 P. M.

Dr. W. N. Bullard will present a paper entitled, "The Increase of Intra-dural Pressure in Head Injuries."

Dr. E. O. Otis will read on "Hospitals and Sanatoria for Consumptives Abroad." The following gentlemen are expected to discuss this paper: Drs. F. I. Knight, V. Y. Bowditch, and A. Worcester.

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology and Hygiene. A regular meeting will be held at 19 Boylston Place, Wednesday, December 15th, at 8 P. M.

At 8 o'clock, short communications by Drs. Brackett, Hoguer and Victor.

At 8.30, Dr. Theobald Smith, "The Tetanus Toxine"; Drs. Munro and Withington will report cases and open the discussion.

E. W. TAYLOR, M.D., Secretary, 416 Marlborough St.

WARNING!

A YOUNG man, who states that he is twenty-three years of age, is going the rounds among physicians, and possibly other professional men, representing that his young wife is in imminent peril from some (variable) cause. He gives a fictitious address and is suspected of being a half-way or entry sneak-thief.

RECENT DEATH.

EDWARD AUGUSTUS WELCH, M.D., M.M.S.S., died in Sutton, November 30, 1897, aged thirty-five years.

BOOKS AND PAMPHLETS RECEIVED.

Surgical Melange. Abdominal Incision for Ascites. Appendicitis, Report of Four Cases. Craniectomies, with Report of Four Cases. By Merrill Ricketts, Ph.B., M.D., Cincinnati, O. Reprints. 1897.

Handbook of Materia Medica, Pharmacy and Therapeutics, including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription Writing. By Samuel O. L. Potter, A.M., M.D., M.R.C.P., Lond., Professor of the Principles and Practice of Medicine and Clinical Medicine in the College of Physicians and Surgeons of San Francisco; Medical Superintendent of St. Mark's Hospital, etc. Sixth edition. Fully revised and greatly enlarged. Philadelphia: P. Blakiston, Son & Co. 1897.

Lecture.

CHARACTERISTICS OF INSANITY.¹

BY WALTER CHANNING, M.D., BROOKLINE, MASS.

(Concluded from No. 24, p. 588.)

THERE is danger that students may become impressed too much with the idea that delusions in mental disease stand out definite and clear cut, being limited to one special, specific subject. This is an error, which should be most carefully guarded against. There is hardly any man, however strong he may be mentally, who could keep any idea alone by itself for many minutes in the field of consciousness. By the association of ideas, others of an allied character spring up, and so even in the pursuit of one subject, there is an interchange and interplay of a multitude of ideas, though there is a continuity and system in their sequence. In the insane there is the same method of mental action, less orderly, more perverted, but following the general rule. Now, there may be one central false belief, as, for instance, in a case of melancholia, the committal of the unpardonable sin. But these words are merely the verbal expression of a tremendous emotional change that has taken place. The patient may have been growing for months depressed. First, it may have been simple morbid conscientiousness; then sorrow for the wrong things he had actually done; then sorrow for his sins of omission; a feeling he was bringing ruin on his family; a consciousness of wickedness; despair at the hopelessness of the future; certainty that he was eternally lost; and, finally, the committal of the unpardonable sin. The patient's mental state cannot be summed up by saying he has this particular delusion, but must include all the elements which combined together display the emotional disorder, as well as the purely psychical. The temperature is pathognomonic of typhoid fever, this particular delusion of melancholia; yet in neither case are we giving more than one factor in the disease.

In mental disease, therefore, you may be sure you will find more than the single delusion, if you happen to have picked that out, as often you cannot. You will find a *delusional state, characteristic of the disease, rather than a single delusion*. The mind will be permeated, and often honeycombed, by ramifications of the false beliefs. Many things, perhaps most things, the patient does will be tinged by the character of his disease where he has a chance to act out his own personality with any freedom. In studying mental disease one is made strikingly aware of how little originality there is among average men. We are creatures of habit, the result of our close family and communal life. Even the insane, who more than any other class throw off the shackles and restraints of social convention, are kept in grooves and ruts, and, as they wear clothes, fit themselves in after a fashion. Their docility and amenability (often they are much more manageable than the sane), give the impression of adaptability, but underneath the surface will be found characteristic and consistent indications of the mental disease. The threads are all there, out of which we may with patience weave a diagnosis. To do this successfully we must bear in mind two things: (1) not to be disappointed if we do not discover the presence of a single well-defined delusion; (2) not to be surprised if the

surface indications of the disease are not very noticeable.

The varieties of delusion are necessarily very numerous, depending both on the form of the disease and the country, race, surroundings and intelligence of the insane person. One writer enumerated fifty-two varieties of delusion he had noticed. While the innate character of the false belief may be of the same nature from one period of time to another, the outward way it expresses itself may change. For instance, those who have delusions of persecution often think they are visited in their rooms at night, for the purpose of being injured. Formerly, their rooms were violently broken into, or there was a trap-door in the floor through which the visitor entered. Later, electrical wires were carried to their rooms, and powerful shocks of electricity were administered. At present, they add the telephone to the electric batteries, and often receive threatening and terrible messages from their enemies. Even the phonograph is occasionally brought into requisition.

According to Ball and Ritti, delusions met with in mental disease may be divided into the following:

- (1) Delusions of satisfaction, of grandeur, of riches.
- (2) Delusions of humility, despair, ruin, culpability.
- (3) Delusions of persecution.
- (4) Hypochondriacal delusions.
- (5) Religious delusions.
- (6) Erotic delusions.
- (7) Delusions of bodily transformation.⁷

Nearly, if not all these classes of delusions will be mentioned in describing the various forms of mental disease in subsequent lectures; they need not, therefore, be mentioned in detail here.

The physical evolution of delusions in a subject on which we have little light; but as a prelude to the subject which will next occupy us, namely, hallucinations, Kirchhoff's views are of interest:

"In patients," he says, "belonging to the most different classes, and in all parts of the world, we always find certain definite series of delusions in constant repetition. In many such, series of ideas persist throughout the entire course of the disease; they are called fundamental, or primordial. Like central hallucinations and imperative concepts, they either develop directly in the diseased brain, or are excited by slight external impressions, or by processes within the body. The latter factor requires some explanation. In ordinary health, but more frequently in morbid conditions, irradiated sensations in the body are often associated with irritations in the same, or other nerve tracts. For example, auditory impressions often produce sensations of light, or colors give rise to auditory impressions. In such cases of irradiation it can often be proved that the origins of both nerves lie adjacent to one another. In a similar way the development of certain delusions is connected with sensations located in adjacent parts of the brain. But as the expression in speech of these associated sensations always revolves within very narrow circles, the contents of the associated concepts are also limited by certain individual ideas and words, and these recur constantly in all individuals, after the same internal stimulus. This sheds light on the uniformity of so many delusions in different individuals. They must develop in certain anatomical tracts, and find expression only in generally known terms of speech."⁸

¹ A lecture delivered to the students of the Tufts College Medical School.

⁷ Practical Manual of Mental Medicine, E. Régis, p. 64.

⁸ Handbook of Insanity, E. T. Kirchhoff, p. 76.

Hallucinations have been defined by Clouston as "false beliefs in sense impressions." Dr. Stearns calls them "false perceptions." Griesinger defines them as "subjective sensorial images, which are, however, projected outward, and thereby become apparently objects and realities." Either one of these definitions is, in a way, a good one, and worthy of consideration. That of Clouston is simple, and easily remembered. The only criticism to be made of it is that it possibly in some cases might be applicable to delusion, as well as hallucination. Of course, a complete definition ought to stand clearly and definitely without qualification for the word or term it is intended to define, and for nothing else. It should not have two meanings.

Another criticism of almost any definition might be that it would make hallucinations appear to be the result of disturbed psychical processes on the one hand, or disturbed sensory ones alone on the other. At present it would appear to be the case that they are of mixed or psycho-sensorial origin, which admits in their production both a sensory and psychic element. Régis thinks there can be "no doubt of the physical element in the genesis of hallucination because of the finding of various lesions in the sensory organs involved, in their nerves, in the thalami, and corpora striata, in sensory centre of the cortex."

Twenty years ago hallucinations used to be defined as "errors of sensation," showing that at that time they were regarded as a physical rather than a psychical lesion. And in observing a patient where the hallucination is well marked the sensory anomaly is what chiefly impresses one, often to a degree to lead one to momentarily overlook the other symptoms of the disease. A patient will say, for instance, that he hears a voice on the other side of the door, when you are talking with him. He may be saying nothing in any way suggestive of mental disease; you suddenly notice that he begins to listen intently, then directs his attention toward the door, as if he heard something; finally, he walks toward it, and satisfies himself not only that he hears a voice, but that it is, perhaps, the voice of his father.

What impressed me in this case was the perversion of the sensation of hearing. It seemed as if there must be some lesion in the auditory centre which was at the bottom of the misinterpretation. It was hard to get away from this conclusion. Yet, on reasoning further, you will see that the sound of the voice grew out of nothing external. My voice was not mistaken for the father's (which would have been an illusion); no other sound of any kind was to be heard anywhere, so that there was no chance in that way for a mistake. Where, then, did the voice come from? We must answer, from the patient's own mind; in other words, it was a wholly subjective phenomenon. It was not only a voice, but the voice of a particular person; which further demonstrates the falseness of the perception. In this case, as in most others, it will be found that delusions are woven into the hallucinations, and practically give them their form and coloring—a proof of their psychical character. The subject of this hallucination had many delusions concerning his father, about whom he was constantly talking, and always wanting to see; it was in keeping with the development of the disease that it should be his voice he heard. He might have heard his father talking from a longer distance, or from some unusual place, like the roof, but he was a quiet-mannered, dignified young

man, and it was consistent with his character that he should not shout at his father, but talk to him from a point near by. Often in studying cases of mental disease you may be able to reconstruct the normal personality of patients from what you can see of their tendencies and peculiarities.

Clouston attempts to account for hallucinations in this way: "We may either suppose that, through morbid activity in the nutrition and energizing of the centres of sensation, those molecular changes, which each previous perception had left, are rendered more vivid, and more like the original, as when a photograph by the stereoscope is made to look real and solid; or through failure in the judging and comparing power of the brain, those faint images which we in health call memories, are actually mistaken for real perceptions of real impressions on the senses, just as when in a dim light, and dreaming humor, the pictures on the wall stand out as real men and women."⁹

"The voices heard are so natural, and the conviction of their existence so irresistible," as Régis says, "that very intelligent patients, physicians, and alienists, themselves will not suffer a doubt, and have recourse in explaining their existence to all kinds of incredible and absurd interpretations; for example, to the intervention of various forces, electricity, acoustic tubes, the phonograph, etc."¹⁰

There are as many species of hallucinations as there are senses, but there are numerous varieties. The chief kind is that of hearing, or *auditory hallucinations*. These generally take the form of voices talking directly to the patient. Their character depends on the nature of the case. If exaltation is present, they will be cheerful, agreeable, or grand and inspiring voices. They may even come from God, or the Virgin Mary. If depression is present, they will be gloomy, despondent, telling the patient of his wickedness, and commanding him not to eat, or drink. If the case is one of delusions of persecution, the voices will be of a threatening, or denunciatory character, and usually come from the enemy. They warn the patient of intended injury, perhaps of designs to kill him; and command him to kill first, as the only way of saving his life.

Hallucinations of hearing are not often of a pleasant nature, but rather of a painful one. They are particularly characteristic of the cases of persecutory disease, a point to which I wish especially to call your attention, as of medico-legal importance. Homicides committed by insane people are often done under the command of a voice, which is absolutely irresistible. Look most carefully for hallucinations of hearing when you examine an alleged insane murderer. He often will make no reference to any voice, or false hearing for various reasons, one of which, and the one that concerns us here, being that after he has obeyed the command of the voice, he hears it no more, and naturally, as you will perceive on reflection, for the deed was in the nature of an explosion, and its consummation is followed by a period of relief from the previous mental tension. Nothing is left for the present to be commanded. In trying to get your clue for the auditory hallucination, you may be told no more then: "He had to do it" (the murder)—"He was told to do it"—"It was a put up job"—"He couldn't help it"—"He didn't have anything to do

⁹ Clinical Lectures on Mental Diseases, T. S. Clouston, p. 139.

¹⁰ Practical Manual of Mental Medicine, E. Régis, p. 69.

with it." All of these statements carefully analyzed, will turn out to be remote references to the hallucination and should lead to further investigation.

False hearing is not limited to one voice, though as above said, it takes its character largely from the form of disease, and individuality of the patient. I had a patient, who heard in the house usually only one voice, but when he walked in the street he heard a great many. All the voices told him what a bad man he was, and purposed to generally expose him. Sometimes the voice is constantly active, keeping up a lively conversation, as in a patient I have, who at the same time carries on a rational conversation with me, and a less rational one with a voice located a little behind her, so that she has to turn her head a little, when trying to catch what it says. The voice generally says very much the same thing, so that she answers it rather mechanically. It tells her that every thing she does is just right, and approves of what she wants to do, which makes her more difficult to manage, as she has many bad habits, which have to be corrected. She sometimes thinks she is to be buried alive, which I think another voice tells her. The first voice, and her own seem to be limited to her own thoughts, one asking questions, the other answering—hence of psychical origin.

Auditory hallucinations have always been regarded as a very grave and practically hopeless symptom from a prognostic point of view, indicating that the disease has become organic. At present we should say a case in which they were found was serious, but not hopeless. This change in opinion is owing to our better knowledge of mental disease, and the discovery of such hallucinations in curable cases where we had not before noticed them.

Visual hallucinations are much less common than the above. They may occur in company with them or alone, perhaps generally alone. They are, of course, false perceptions of sight. Objects are seen which have only a subjective existence. A patient I had saw men at night who came to his room to carry him off to prison. He had no auditory hallucinations, therefore he explained their making no noise by saying they wore felt slippers. Objects seen may be ordinary persons, or the most exalted personages; or places, terrifying spectacles, pleasing sights. Things of a disagreeable nature are oftenest seen at night, and take the form of robbers, murderers, electrical machinery; in women, men who attempt to outrage them, etc. The prognosis where these hallucinations exist, I regard as serious in proportion to the degree they have become organized, but they do not usually indicate a form of mental disease dangerous to others, and are more curable than auditory hallucinations.

Tactile hallucinations, or false perceptions of touch, are not common. As far as my own observation goes they can be more directly attributed to physical causes than those mentioned above. They are often due to imperfect nutrition of the skin, and consequent irritation of the cutaneous terminal nerve filaments. They are perversions of cutaneous sensation, which are subjectively falsely interpreted. The patients feel things on the hands and skin, which may be skin disease or insects or filth. Out of these false perceptions (as it appears to me) sometimes grow the delusions of filth and contamination. The prognosis is not very favorable in these cases. They may recover after a time, or get better, but are very obstinate.

Hallucinations of taste and smell are also rare. They are false perceptions of these senses, and also lead one to regard them as arising in large part out of a physical background. In some cases taste and smell or either one, may be altogether abrogated. I remember one such case, a woman who became mildly depressed after the birth of her first child. She had so largely lost her sense of smell that violets and other flowers had no odor at all to her. Her sense of taste was blunted, but not wholly lost. As she began to get better, she gradually recovered both smell and taste. In health there are frequent perversions of these senses, as one easily discovers on making an investigation.

It is quite common for patients to think they have poison in their food. This idea may arise as a delusion in the mind of a diseased victim of persecution. But it may further develop into an hallucination, and the patient will see the arsenic put in his food, or taste it on his tongue as a fine powder. The hallucinations of smell take the form of perceiving horrible odors, such as sulphurated hydrogen, or ammonia, or some deadly and noxious gas. Occasionally, I have known a patient to suddenly turn around, and perhaps hold his nose. Being interrogated as to what was the matter, he has said: "he could not breathe there was such a stench." If these hallucinations are not well defined and evanescent they have no serious prognostic import, but where they are very dominant, so that a patient becomes suspicious because of the poison he sees, or is all the time trying to escape from the noxious vapors, the disease has become or is becoming fixed, and the prognosis is therefore unfavorable.

In addition to the specific forms of hallucinations already spoken of there are others of a more general character, especially those which are referred to the genital organs, which are usually of a painful character, and occur in the persecutory form of mental disease. In conclusion, brief mention must be made of the third group of what I have called classical characteristics of insanity, namely, illusions.

Illusions are mistaken perceptions. The definition of Régis is: "The false interpretation of a perceived sensation." An hallucination is wholly subjective or invented; an illusion is a distortion, a sense deception. If we refer to the young man already spoken of who heard his father's voice on the other side of the door, you will remember we called his doing so an auditory hallucination because no voice was heard. But if some one proved to him not to be his father had actually spoken, and he had said, that is my father's voice, he would have been the subject of an auditory illusion. He insisted on it that much of the furniture in the room had come from his father's house, and was sure that the stable was his father's stable. These were illusions of sight, which are the most common kind.

Mistakes in identity also come under this head. The same young man recognized several people in the house as persons he had previously known, and even spoke to them and called them by name, yet he had never seen one of them before. Another patient addressed an unknown lady in a familiar way as his wife, and in spite of her protestations was satisfied of her identity. He also thought that he recognized her voice in the room over his head, and was sure when he heard the furniture being moved about, that she was being attacked and maltreated. These were auditory illusions.

Illusions of taste and smell are not uncommon. Salt and sugar are sometimes regarded as arsenic, strychnia

and other poisons. Milk has the taste of poison. Egg-nogs are made of rotten eggs. Rare beef looks and tastes like human flesh. Any smell is like putrid flesh, or decaying matter, or sewer-gas.

Illusions of cutaneous sensation are occasionally met with, as in a patient with a dry and badly-nourished skin, who mistook the irritation and itching for insects which were crawling over her.

Illusions occur in both curable and incurable cases, and are not regarded as unfavorable indications in the prognosis. Uncombined with hallucinations, this is true; combined with them, the opposite is the case.

THE INSANE POOR IN PRIVATE DWELLINGS IN MASSACHUSETTS.

BY A. R. MOULTON, M.D., PHILADELPHIA, PA.,

Late Inspector of Institutions, Massachusetts State Board of Lunacy and Charity.

In the *Boston Medical and Surgical Journal* of November 4, 1897, is a paper bearing the above title, contributed by Sir Arthur Mitchell, Ex-Commissioner in Lunacy of Scotland, which is, in fact, a review of that portion of the work of the Massachusetts State Board of Lunacy and Charity which refers to the boarded-out insane, as set forth in its report for 1895-96. While the review (one might almost denominate it a *criticism*) is phrased in such courteous language as its distinguished author would only use, it is in part so misleading that I deem a few remarks bearing upon this matter not out of place.

Not now being connected with the Board of Lunacy and Charity, nor a resident of Massachusetts, I cannot be charged with obligation or bias.

To one familiar with the lunacy laws of Massachusetts, and with the methods of the public authorities in administering the same, the conclusions of the Board of Lunacy and Charity and its analysis of the boarding-out system must appear fair and convincing; indeed, the unofficial remarks of Dr. J. L. Hildreth, a member of the State Board, in his paper upon the "Public Care of the Insane in Massachusetts," the first section of which is published in the same number of the *JOURNAL* as Sir Arthur's paper, coincide precisely with my experiences, and bear out the opinions of others who have had practical contact with this work in the United States and elsewhere. So fairly are the remarks summarized by the doctor that I venture to quote the paragraph containing them:

"Since 1886 the Board has had authority to place in families insane patients of the quiet and chronic class. Experience has shown that convalescent cases receive the most benefit from this system. There are comparatively few patients who receive more benefit than if they remained in a hospital. Neither the hospitals nor the Commonwealth have been very much benefited by the system, and there are obvious reasons connected with the welfare of the community at large which suggest, that under the present laws the system should be extended very carefully, if at all."

There are three classes of patients in Massachusetts lunatic hospitals, namely, State, town and private patients; which titles indicate the sources of their support in the hospitals. On September 30, 1896, there

were 5,868 patients in the Massachusetts State institutions, classified as follows: 1,445 as State, 3,819 as town, and 604 as private patients. Under the law the Board of Lunacy and Charity may place in families quiet, harmless chronic patients of the State class only. Its officers, however, act as agents for the placing of town and private patients, and of the 129 patients in families under its supervision on September 30, 1896, 75 were supported by towns and 16 were supported by individuals. Though persistent effort has been made by the board to place out patients, there were on September 30, 1897, only 121 in families, and they were supported as follows: 34 by the State, 69 by towns, 17 by individuals, and 4 were self-supporting, or cared for in families at no expense, their labor being sufficient compensation. State patients are those who have no known settlement in the Commonwealth, and they are a charge to the State. The board, through its officers, undertakes to determine the settlement of all such paupers, and when it is found to be in a given town of the State, the patient becomes a charge of that town. If, after inquiry, it is ascertained that a patient supported by the Commonwealth belongs to another State or country, the individual is very properly sent to that place, if in the judgment of the hospital superintendent he is well enough to endure the journey, usually accompanied by a proper care-taker. In exceptional cases the patient is unaccompanied, but never unless supposed to be sufficiently strong, mentally and physically, to travel alone.

For a number of years there has been a disposition on the part of overseers of the poor of towns to remove their patients from hospitals to almshouses, most of which are wholly unsuited to the care of the insane, and in none of which, as I found those places from 1888 to 1891, nearly so suitable for any insane person as is the least desirable State establishment.

There remain, then, in the hospitals for the Board of Lunacy and Charity to draw from, for family care, the small number of State patients whose settlement is undetermined, who are quiet and harmless, and whose disorder has become chronic; for it must be remembered that State patients whose disorder is acute are not legally permissible for boarding out. A considerable number of State patients have a known settlement in other States, but they are too excited, or otherwise unsuitable to move, and are therefore not usually proper cases for family care.

There is a considerable number of town patients who might be placed in families, or such was the case a few years ago, and I have no reason to suppose that the conditions have materially changed; but the consent of the overseers of the poor must first be obtained, and as the suggestion to those officials that a particular patient is suitable for family care usually results in landing the invalid in a wretched almshouse, a conscientious agent of the State Board will hesitate before suggesting that which almost of necessity will result in injury to the lunatic, for the average overseer of the poor is actuated chiefly by the question of cost in his care of the insane, and unless the expense to the board of a town patient is less with the private family than it would be in the almshouse, he will almost certainly go there if removed from the hospital before recovery takes place.

The conditions are quite different with private patients; the friends are able to provide for such cases

in their own homes when they are in a condition warranting removal from the hospitals, and the small number of this class boarded out includes cases which for certain reasons should not return to their families, or that have no homes to receive them.

Then, too, another element has recently become operative which has undoubtedly interfered with the boarding out of patients; and to one familiar with the work, and of unbiased judgment, the wonder is, not that so few have been boarded out within the past two years, but that the State Board has succeeded in placing out any during that time. I refer to the occupancy of the Medfield Asylum, which institution has received more than a thousand pauper patients, all transferred from the State hospitals, thus relieving them to that extent of their crowded condition. There is not that incentive existing which formerly obtained for the superintendents to relieve their hospitals numerically by recommending a few to the inspector for boarding out.

When conducting that department of the Board of Lunacy and Charity which includes the work of boarding out insane, there were more applicants for boarders than patients available for placing out; but it by no means follows that every family which asks for patients to board is a suitable one for their care; indeed, the circumstances in New England, especially in Massachusetts, are such that the list of suitable care-takers is a limited one, and the State Board is to be commended that it does not lose sight of its duty to the community, and that it has not become so blinded as to fail to look beyond the family and to consider the proposed environment. The recent shooting of a citizen by a "harmless" lunatic, removed from the hospital against advice, should be a lesson and warning.¹

I frequently had patients recommended to me by superintendents for boarding out whom I could not place, for the reason that, though there were families desiring patients, I knew they would not, or could not, give the patient named suitable care, or the latter was the charge of a town whose overseers disapproved of the boarding-out system.

A good deal has been said about the "home comforts and family surroundings" of patients placed in private houses, and the Scotch commissioners make much of this. There is an element of truth in the sentiment; but neither in Scotland, where I visited a large number of families said to be typical ones, nor in Massachusetts, where I am familiar with the practice, is it a fact that boarded-out patients are, as a rule, taken into the family circle. Even in Scotland, where the crofter's homes are often only two-roomed houses, the patients, as I saw them, seldom eat with the family, though they live in closer proximity to its members than do the patients in Massachusetts, for I saw one woman patient there who slept in the same room — the kitchen — with the husband and wife of the household. In Massachusetts I found some families who permitted their patients to gather around the table of an evening, and who might join in the conversation; but the rule was for the patients to sit by themselves, usually in the kitchen, where they also took their meals, not with the family, or if at the family table, at a different time.²

The circumstances of the care-takers in Massachu-

setts are quite unlike those in Scotland. As I have pointed out elsewhere,² the distinction between the Scotch guardians and those of Massachusetts consists largely in difference in material comforts; for while the care-takers in Scotland feel obliged from stress of circumstances to retain even troublesome patients, those in Massachusetts are, as a rule, so well off that the boarding of patients is not their only or chief means of subsistence, and none but the most placid and least troublesome patients will be retained. The patients in the Scotch asylums are of a much more quiet and orderly class than are those of that nationality which form the asylum majority in Massachusetts, and it is my conviction that did the Scotch authorities have to deal with the latter element they would have a better appreciation of the limitations that are a vital factor in Massachusetts. Conscientious workers under like circumstances will accomplish nearly similar results.

It may be thought that I disapprove of the boarding out of patients; but instead, I am very much in favor of it under proper conditions and limitations.

Some of Sir Arthur Mitchell's criticisms are weighty and to the point, but much of his paper is misleading, due probably to lack of information of the existing conditions in Massachusetts. I fully agree with him that "all the insane poor, *however provided for*, should be as much under the care of the State as those of them who are in asylums," and that "no almshouse should be allowed to receive insane inmates which is not licensed to do so by some State authority, the license being granted on well-considered conditions," similar to those in Scotland.

Were all the indigent insane wards of the State, many of those now languishing in almshouses could be much better provided for in families; and the large number of chronic patients in hospitals now classed as town cases would furnish a ripe field from which to supply boarders to new care-takers as they might be developed. Such a method would form a system of boarded-out insane indeed, in place of the present *experiment*, which many think has been "a failure from the beginning."

The State Board of Lunacy and Charity makes the very pertinent remark that the boarding-out system "seems to apply most happily to those who are on the road to recovery"; and Dr. Hildreth, in the paragraph already quoted, expresses the same thought, which is in accord with the experience of all who have had much to do with the insane. In pursuance of just this line, and partly for the purposes indicated, have country houses and seaside villas been established in connection with numerous hospitals both at home and abroad. It is a common experience that for the lack of a suitable place to send them, a few patients are retained in hospitals to their detriment. Were suitable families available, such cases might possibly be stimulated, dementia prevented, and convalescence hastened.

It seems an opportune time, then, to very materially broaden the work of the "boarding-out system" in Massachusetts; and if the State is not ready for the radical changes in the poor-laws herein indicated, which would place all its indigent insane under the supervision and care of the Board of Lunacy, it would not object to the beneficent measures suggested for the insane not yet become chronic.

¹ The case referred to is that of a man, taken from the Northampton Lunatic Hospital by the overseers of the poor, who after roaming the streets for several years finally quarrelled with a neighbor and suddenly, without warning, shot him. The man is now in jail awaiting trial.

² Thirteenth Annual Report of the State Board of Lunacy and Charity.

A GUNSHOT WOUND OF THE HEAD.¹

BY WILLIAM D. SWAN, M.D., CAMBRIDGE.

No class of injuries has received more attention of late years, from a scientific and surgical point of view, than gunshot wounds. Also, with a view to determine the destructive force of new missiles, a vast number of these injuries have been carefully examined, and innumerable experiments have been made on dead bodies and every conceivable kind of material, and results carefully noted. Results of such work are of great value in the examination of wounds, and the determination of instruments and conditions under which they were inflicted. I have been unable to find a case parallel to the following; and while it may not be unique in the history of gunshot wounds, it at least is unusual and interesting from a medico-legal point of view.

The body of a man was found in the woods of Arlington, June 19, 1892. The body lay on the back, arms at the sides. There was a pool of blood beneath and around the head. A pistol lay on the belly. There was no disorder of the clothing or other evidence of a struggle. Rigor mortis was present. No odor of decomposition. Some fresh fly-blows about the head. The pistol was a revolver of cheap pattern, .38-calibre, short barrel. The chambers contained one empty cartridge and one loaded one showing impress of the hammer on its rim. There was not a small round hole in the right side of the head, with blackened edges and surrounded by powder marks. There was a large, irregular-shaped scalp wound in the top of the head, which presented none of the ordinary characteristics of a pistol wound. There was no blood or injury in the mouth or nostrils. There were no means of identification.

An autopsy was held the following morning in the presence of Medical Examiner Durell, of Somerville, and Chief Meade of Arlington, probably thirty-six to forty-eight hours after death.

Body of a man upwards of fifty years of age—lean, long-armed, muscular and well formed. Over coronal suture in the median line a star-shaped, or roughly cross-shaped wound of the scalp, with gaping edges, two inches by one and three-quarters inches in extent. Skin and hair at the edges not burned or blackened. Beneath this wound an irregularly round hole in the skull, three-fourths of an inch in diameter at outer table, and much larger at the inner table. Surface of the skull and periosteum and inner side of scalp about this hole black, and covered with grains of powder and some minute scraps of lead. Frontoparietal suture on the right side separated one-sixth of an inch; on the left side a fracture of the parietal from the bullet hole almost to auditory canal, and thence to left orbit, edges of parietal lobe separated one-sixth of an inch and the inferior edge of the parietal elevated and separated one-quarter of an inch from the temporal. Brain much lacerated in a vertical direction beneath the hole in the vertex, and blood extravasated. At a depth of three inches at the base of the brain were found several pieces of bone and a .38-calibre bullet of which the forward part was flattened and bright and the edges thin and turned back. Considerable blood in the left lateral ventricle.

Above the right eye and along the edge of orbital part of the frontal and the lesser wing of the sphenoid bones the brain adherent by thickened membranes. Considerable cicatricial tissue at this point and old loss of brain substance. Neighboring tissues yellowish. At the tip of the lesser wing of the sphenoid bone and inside the skull, covered with fibrous extension of the dura-mater, is part of a bullet of smaller calibre than .38, of uniform dull lead color. Skull external to this shows evidence of an old fracture, and a small piece of lead is embedded in the bone exteriorly. An old, indistinct, small, round cicatrix found in the skin two inches above and about the same distance anterior to the external auditory canal on right temple. Examination of the organs of chest and abdomen showed nothing of importance. The stomach and intestines were nearly empty. There were no powder-marks on the hands.

The man was fully identified from the photograph, and it was learned that he had attempted suicide by shooting himself in the right temple about three years previous. The fact of suicide being established, it remains only to consider the peculiar aspect of the wound.

The explosive effect of a bullet wound is due to lateral expansion in solid substances and to hydrostatic pressure in fluid or semi-fluid matter. The lateral expansion causes fissuring of a bone for instance, and as a general rule the greater the index of cohesion the more extensive is the splintering or fissuring speed of the missile. Here is an uncertain element, for the element of elasticity sometimes makes the injuries less extensive with a high speed than with a low. In addition to this expansive effect, causing a long fissure on each side of the bullet wound in the skull, is the hydrostatic result of rapid compression of the semi-fluid brain mass confined in the cranium. The molecules of a liquid are readily displaced, and a greater effect will be produced on them by a relatively lower velocity, but with high velocity it is enormous. A rifle bullet will pass through an empty tin can, making two round holes; but if the same can be filled with water, it will be burst and torn to pieces by the impact of the bullet on the water. The base of the skull escapes injury because the dome is already split by the expansive effect of direct impact.

The last and most unusual cause is the direct expansive effect of the powder gases, as shown especially in the splitting of the scalp and the deposit of powder residuum on the inside of the scalp and the separation of the scalp from the bone.

It seems probable that the man, in his second attempt at suicide, chose the top of his head as a more vulnerable spot than his temple, where he had been unsuccessful before. He sat down in a secluded spot, bent his head forward and holding the pistol in both hands, perhaps with a thumb on the trigger, and with the muzzle to the top of his head, fired; the hammer clicked on the cartridge and there was no explosion. With nervous haste and desperation he recoiled the pistol and pressing the muzzle firmly against his head, again pressed the trigger and this time with the desired results. As he fell back dead, his hands fell at his sides, depositing the pistol on his abdomen.

There is a case reported by Ogston of a man who fired a pistol with the muzzle pressed against his breast, with the result that the pistol was blown away and he received only a slight contusion of the skin of the

¹ Read before the Massachusetts Medico-Legal Society, June 8, 1897.

breast. I cannot believe that that is a result to be depended upon.

An important point in determining whether a pistol wound is self-inflicted is the presence of powder smut on the hands. I have lately seen a case of suicide by shooting in the right side of the head, in which the fingers and palm of the left hand were blackened by powder. This bullet wound in the right side of the head was much bruised and blackened. This individual must have steadied the muzzle of the pistol with his left hand.

SUDDEN DEATH DUE TO ALCOHOLISM.¹

BY E. P. HURD, M.D.,
Medical Examiner, Newburyport, Mass.

THE following cases illustrate the difficulties which sometimes present themselves to the medical examiner when called to diagnose sudden death due to alcohol poisoning from death by some other poison, as opium, or by apoplexy.

CASE I. A. B., age thirty-five years, a Swede, hired man and farm-worker, residing in Shepton, Canada, was found one evening dead by the roadside not far from his home. The body was recognized by a passer-by and removed to a barn. Being summoned, I viewed the body and the situation where it was found, and noted that there was no blood on the ground, and that there were no marks of violence on the corpse. The coronor was notified, and arrived early the next day.

The following facts were brought out at the inquest: B. was of intemperate habits, and had been for several days on a spree. On the evening of his death he had been to the neighboring village, and after taking several drinks at the hotel, he had started for home with a whiskey bottle replenished at the bar in his pocket. This was found, nearly empty, by the roadside near the place where he died.

The coronor ordered an autopsy, the details of which are as follows: A man of medium height, light complexion, rather stout and of bloated appearance. Post-mortem rigidity very pronounced. Large ecchymoses on dependent parts (hypostatic congestion), great turgidity and purple aspect of face and lips, a frothy sanguinolent fluid escaping from mouth. Stomach exhibited a patchy inflammation and some ecchymoses; contained half a pint of a sour, sanguinolent liquid smelling of whiskey. Diffuse redness of the mucous membrane of the small intestines. Liver and spleen congested, the spleen softened. Heart and kidneys normal. Lungs edematous; mucosa of bronchi injected.

Cerebral meninges congested; sinuses turgid; venous network of pia distended; punctiform hemorrhages on surface of cortex in both hemispheres. No apoplectic effusion in centrum ovale or in ventricles.

The fact of alcoholism was proved by the autopsy, for these lesions were undoubtedly due to alcohol. The coronor's jury, therefore, brought in a verdict of sudden death due to alcohol poisoning. Query: Why did A. B., a robust man, with sound heart and no disease of viscera incompatible with a much longer existence, come to his death so suddenly? It was said that he had often withstood more liquor than he had imbibed in this drunken debauch. This was in

the month of October, and the deceased was thinly clad, with summer suit and no overcoat. May the chilliness of the season have had something to do with this sudden death? It is known that alcohol retards processes by which animal heat is produced, hindering the transformations of oxyhemoglobin in the blood, and inebriates poorly resist a severe chill. It has been proved that blood cooled below a certain point has a paralyzing influence on the nerve centres, including the cardiac and respiratory centres in the bulb.

CASE II. D. F., aged seventy-five years, farmer, of good early antecedents, had for several years been an inebriate. When I called, on the evening of March 16, 1868, to see him, I found him in bed, in deep coma, with heavy, stertorous breathing, bloated, livid countenance, feeble, flickering pulse—in fact, nearly dead. There was a perceptible alcoholic odor in the breath. That afternoon, as appeared from the testimony of one of his family, D. F. had drunk heavily. It was said that he had lived on whiskey, as, owing to a bad stomach, he had been unable to take food. The autopsy, performed next day, showed a stomach thickened and inflamed with hemorrhagic extravasations and erosions of the mucous membrane. About four ounces of thick mucus was removed from the stomach, and somewhat less of a prune-juice liquid redolent of alcohol. A cirrhotic liver with sclerotic changes not advanced and a fatty heart were also found. The membranes of the brain were thickened and hyperemic, and there was a large subdural clot on the left side covering a large part of that hemisphere. The ventricles were distended with blood and serum, and there was some edema of the convolutions of the right hemisphere. This case was entered as sudden death by apoplexy of which the exciting cause was alcohol.

As physicians and as medical examiners, we are continually meeting instances where the diagnosis of the coma lies between apoplexy, narcotic poisoning, and alcohol poisoning—that condition of the latter where the person is supposed to be dead drunk. In former days when bleeding was in vogue, I have known a person to be bled for apoplexy who was simply dead drunk, and who recovered completely after several hours. I have also known patients to be regarded as dead drunk who were in the coma of apoplexy. As Watson says: "Coma is coma, from whatever cause, and you must seek to ascertain the cause in the history and other circumstances of the case. You inquire whether he is known to have been drinking; you try if you can perceive the odor of wine or brandy in his breath; you endeavor to make out whether he has been low-spirited or in known difficulties; in short, whether it is likely that he may have swallowed poison. But from the symptoms and actual condition of the sensorial and motor functions you cannot solve the question."

The two cases above reported occurred many years ago, and no chemical analysis was made of the contents of the stomachs; it was, however, sufficiently apparent from the odor and from other circumstances that the liquid found in the stomach was impregnated with alcohol.

The following case of sudden death in an inebriate was undoubtedly due remotely to alcohol.

CASE III. F. F., a Norwegian, silversmith, aged forty years, was admitted to the Houston Institute, Newburyport, July 4, 1893. He came of a healthy,

¹ Read at the Annual Meeting of the Massachusetts Medico-Legal Society, June 8, 1897.

long-lived family, and had never been sick prior to entering the institute. He had been a hard drinker for twelve years — daily drams, frequent spree. He had been also an inveterate smoker. The physician at the institute had noticed a weak, intermittent pulse and diagnosed a "tobacco heart." He was placed under the usual treatment for inebriety, tobacco and alcohol being soon completely withdrawn.

August 7th he left the institute "cured" but with more or less pain and discomfort in precordial region with shortness of breath, and complete inability for exertion; he could no longer work at his trade. The night of the 17th of August he was unable to sleep on account of severe stabbing, burning pain in heart, general restlessness and distress. In the morning, he walked to the institute (a short distance) for relief, became rapidly worse, was taken to his home, and died on the way.

On requisition of the mayor, I performed an autopsy on the afternoon of the 18th. Death appeared to be due to fatty disease of the heart muscle, unaccompanied by any fibrosis or occlusion of the coronaries. The accumulation of fat exterior to the sarcolemma was phenomenal, considering that adipose development elsewhere was not up to the normal in a spare, anemic subject; the interfascicular connective tissue was infiltrated with fat in the form of yellowish streaks and deposits crowding and compressing the muscular fibres, which presented a yellowish or fawn color; the heart walls were soft and flabby, and the myocardium in places could be easily torn through or broken down by pressure of the finger. The whole of the left ventricle seemed enveloped in a fatty layer under the visceral pericardium, thinning out and disappearing toward the apex; the coronary arteries, though normal in appearance, were buried in adipose substance in the first part of their course. A section through the middle of the left ventricular wall showed the myocardium interpenetrated by and stuffed with adipose matter. The solid organs of the abdomen were congested and more or less altered. The spleen was enlarged and softened; its pulp of the consistence of *bouillie*. The liver was enormously swollen, firm and hard, cutting with great resistance. The kidneys were enlarged and hyperemic, blood flowing freely on section. Stomach empty and normal in size; no thickening of walls and only a little patchy redness of mucosa about greater curvature. I returned this death as the result of fatty disease of the heart and other lesions, probably due to chronic poisoning by alcohol.

After much reflection on this case and careful study of my notes made at the time, I am convinced that this was a true case of what the French writers call *surcharge graisseuse* — first, fatty increase, second, fatty transformation. It was not primarily fatty degeneration or parenchymatosis myocarditis. Doubtless other factors besides alcohol were operative here to, so to speak, submerge this heart by adipose. When this man went to the institute he was comparatively well, able to work, though under the dominance of his evil habits. In one month's time the organ most essential to the sustenance and nutrition of the whole economy was hopelessly smitten in its vitality.

Interesting questions present themselves here; but they are all unsolvable. How far were the lesions in this case due to alcohol, and what part, if any, had tobacco in their causation? What is the explanation of this etiological rôle (now acknowledged by the best

pathologists) of alcohol in the production of cardiac lipomatosis and steatosis? How far, if at all, were the morbid changes described in this case, and especially the cardiac steatosis, due to suppression of the stimulus of alcohol and tobacco; in other words, did abstinence precipitate the fatal issue?

APPEARANCES OF THE ALIMENTARY CANAL IN SUDDEN DEATH BY ALCOHOLISM.

The effect of alcohol on the digestive tube varies with the dose, the quality and the degree of dilution. That this organ is in some instances very tolerant, long preserving its structure and function unimpaired despite great excesses, is a fact, notwithstanding the asseverations of certain of our school text-books. That the abuse of any alcoholic stimulant does eventually entail inflammatory changes in the alimentary canal is certain. Dujardin-Beaumetz and Andigé, in their experiments on acute and chronic alcoholic poisoning, in animals (principally hogs), found that toxic doses inflame the stomach and intestines even when injected under the skin. Of all the alcohols, ethylic is the least baneful, eight grammes per kilogramme of the animal's weight being a fatal dose. Amyl alcohol (fusel oil) is much more baneful, a dose equal to two grammes per kilogramme being speedily fatal. The effects of ethyl alcohol (spirits of wine) on the stomach are much less pronounced than those of propyl, butyl and methyl alcohol; the latter violently congest and irritate the stomach, cause hemorrhages and obstinate vomiting. The practical lesson is that impure alcohols, such as new rum, and whiskey that has not ripened in casks, and are impregnated with fusel oil (the bane of new liquors), and all such spirits as are fraudulently sophisticated with fusel oil, are much more deleterious than wine and spirits containing only ethyl alcohol, produce more intense inflammatory changes in the digestive tube, and are more likely to be followed by sudden death, generally in coma and sometimes in convulsions.

There are no constant appearances of the stomach and other viscera in alcohol poisoning. In other words, the lesions give no absolutely infallible criteria. There may be uniform redness or there may be redness in patches; there may be petechiæ and ecchymoses of the mucous membrane and punctiform hemorrhages into the gastric cavity, or there may be large extravasations of blood and hemorrhagic erosions, the stomach may be of normal thinness and but slightly injected, or it may be thick and rugous, intensely red in places and black and sloughy in others; and the abdominal viscera may be hard or soft, hypertrophied or shrunken, and yet the death shall have been caused by alcohol poisoning.

It cannot be too much borne in mind that alcohol has a special affinity for the nervous system; or we might say that the nervous system has a sort of chemotoxic affinity for alcohol. In some inebriates the nervous phenomena of alcoholism are far the most marked and the visceral lesions are inconspicuous; even the entire absence of such lesions in a given case would not warrant the affirmation that the sudden death was not due to alcohol. Nor would the failure to obtain a history that the deceased person had prior to death passed through the classic phases of drunkenness (excitement, then perversion, then depression of the faculties and forces) warrant the conclusion that the individual did not die from alcoholism.

"In some cases," says Boelm, "the effects of alcohol

are diametrically opposite [that is, from excitement] having a depressing effect from the very first; and the person goes on to a state of narcotism without any of the ordinary outward signs of drunkenness. The amount of consciousness and rationality retained by the drunken man varies greatly, and is by no means always proportioned to the quantity of poison imbibed. Men who are manifestly drunk often act and transact business for a time with complete reflective faculties, and with a good deal of consideration. Death may occur early in the first stage of drunkenness in consequence of asphyxia and paresis of the heart, but it may occur in the later stages."²

These observations will serve as an introduction to my fourth case.

CASE IV. E. J. C. died suddenly at Grape Island, in Plum Island River, between Newburyport and Ipswich, on the afternoon of August 6, 1896. This woman, considerably under the middle age, strong and robust and of fine physique, was left at the hotel in the afternoon of the date mentioned by her companion, a gentleman from Rowley, in a state of intoxication. The two persons had come down from Rowley in a boat together, and C. had taken copious draughts of whiskey on the way. M., the male companion, stated that he had left C. at the hotel because she was drunk, and he did not know what else to do with her. From an examination of all the evidence, I am inclined to take M.'s statement as the truth. There was, at the same time, the testimony of two parties at the hotel that C, when she entered the hotel did not walk, act or speak like a person actually drunk, nor was any smell of liquor noticed in the breath. There was evidence that the woman took some liquor (furnished by M. from the bar) after arriving at the hotel. M. returned to Rowley in his boat. Shortly afterwards, Mrs. C. rose from her chair, walked across the room, then fell heavily on the floor, and instantly died.

I was summoned by the police from Newburyport, this place being accessible by a straight road over the sand meadows. Dr. Clark, medical examiner of Ipswich, was also summoned, and we both arrived at Grape Island at nearly the same time, my arrival antedating that of Dr. Clark. It was agreed by us to remove the body to Newburyport for an autopsy. The autopsy was held in the afternoon of August 7th. To confine myself to essentials, I may state that we found in the viscera of the abdomen and in the encephalon lesions which could properly be ascribed to chronic alcoholism. The stomach and small intestines were intensely hyperemic, as manifested by a diffuse redness of the mucous membrane and extreme vascular dilatation; there was nothing there to indicate chronic lesion. The liver and spleen were enlarged and softened; the kidneys were very hyperemic, large and soft; blood freely oozed on section. There was some congestion and edema of the lungs and bronchi (perhaps altogether hypostatic). In the encephalon was found an old pachymeningitis existing as a limited lesion along the longitudinal fissure. There was an ecchymosed spot as large as a silver dollar back of the right ear and a corresponding spot within the cranium, and extending to the dura mater, but no free blood; this was evidently produced by the fall, being the part that struck the floor. It was judged that a fall producing a lesion of this kind in a rather stout and heavy woman might cause considerable cerebral concussion. The meninges

were unduly vascular and the sinuses were engorged, but there was no hemorrhage. The heart was normal; the ventricles were empty. Death evidently occurred in systole.

There was found in the stomach a small quantity (about half a pint) of a turbid, somewhat bloody, fluid; this was collected in a bottle and along with the stomach sent to Professor Hills, of Harvard Medical School. In another bottle was sent the urine drawn from the bladder, and in a third, portions of the liver, the spleen and the kidneys. The general public manifested great interest in this case, and there was a wide belief that this woman had died from some poison other than alcohol.

Professor Hills in his report stated that he failed to find any toxic agent excepting alcohol. The presence of that spirit was detected in the stomach, in the urine, and in the other organs. Professor Hills gave as his opinion that the woman died of alcoholism. My own theory was that the fall on the head was an important factor, giving a powerful adjuvant influence to a paralyzing noxa already existing. If this be not so, I fail altogether to understand the suddenness of this death, and can only suggest that now and then alcohol may act as chloroform in rare instances acts — by paralyzing the medulla oblongata before the upper brain is completely subjected to the influence of the poison.³

THE PRESERVATION OF SPECIMENS WITH THEIR NATURAL COLORS BY KAISERLING'S METHOD.¹

BY WILLIAM F. WHITNEY, M.D., BOSTON.

THE necessity for preserving anatomical specimens with their natural colors has always been felt, and the impossibility of retaining the delicate shades which are indicative of many of the morbid processes has always been a great bar to proper teaching of pathology. With the introduction of formaline as a hardening agent and the modifications in its use recently published by Kaiserling,² it seems as if the collections of the future would be able to present something for the student besides variations in shape and size and fractures; for this is all that can be readily seen by him now, and his imagination has to supply the rest.

But it is not only for the instructors, but also for the medical examiner, that this promises to be of advantage; for the soft parts of the body that have been injured can be preserved in this way and shown in court, if necessary, and would often convey much more meaning to the average jury than lengthy technical descriptions.

The method is simple; the only precaution to be observed is not to put too large pieces in the preserving fluid, and to be careful to change them at the

¹ Read before the Massachusetts Medico-Legal Society, June 8, 1897.

² C. Kaiserling: Virchow's Archiv, Bd. 147, s. 359.

³ I add in a footnote that this is the case where the Board of Health of Ipswich, thinking their rights interfered with by the removal of this body to Newburyport (that is, from one town to an adjoining town) without their permission, and believing that the law defining the functions of boards of health gives such boards authority over medical examiners in such cases, who must apply to these boards for consent before they can legally remove bodies out of one town into another — this board, I say, appealed to Justice Saward, of Ipswich, who sustained the view of the board, and fined the undertaker who took the body from Grape Island to Newburyport ten dollars and costs. An appeal was made to the Superior Court, and the case was *nolle prosequi* by District Attorney White, so that, according to this judgment, medical examiners are not amenable to boards of health in the discharge of their duties within the limits of their districts.

² Quoted from Ziemssen's Cyclopaedia, vol. xvii, p. 393, Am. ed.

proper time. As some shrinkage is inevitable, cavities should be distended with absorbent cotton, which, of course, is to be removed when the specimens are changed. Moreover, freshness of the material adds greatly to its chance of good preservation, and soaking in water (whereby the blood coloring matter is diluted) is to be avoided.

Sections should be made with a sharp knife, and the blood which may have been smeared over the surface removed by pressing (not rubbing) a dry, clean cloth upon it. They are then to be submerged entirely in the fluid, best with a layer of absorbent cotton over them. In this manner, portions of the skin showing stab or bullet wounds, or even extensive ecchymosis, could be preserved, a little cotton being inserted to keep the edges of the wound apart.

The preservation of entire large organs is hardly practicable, as careful injection of the vessels is necessary, much of which should be done before their removal from the body.

Bile pigment will diffuse, and therefore the liver and jaundiced organs are the least fitted for this method.

As regards the length of time they will stand, it depends upon how fresh the substances are, and how carefully they are guarded from a bright light. They have stood the test of a year already, and it would be hardly necessary in any legal case to preserve a specimen longer than that.

The following is the method, and the specimens which are shown with this will enable the members to judge for themselves how successful it has been in my hands:

Slices of organs, from three to five centimetres thick, are placed from three to five days in —

Formaline	200 c. c.
Water	1000 c. c.
Nitrate of potash	15 gm.
Acetate of potash	30 gm.

They are then removed, the fluid allowed to drain off and the specimens are placed in —

Alcohol 80 per cent. for six hours, then
Alcohol 95 per cent. for two hours.

From this directly into —

Water	2000
Acetate of potash	200
Glycerine	400

for permanent preservation in a dark place.

Clinical Department.

REPORT OF A CASE OF ASTHMATIC PAROXYSMS TAKING THE PLACE OF EPILEPTIC FITS.

BY L. PIERCE CLARK, M.D.,
First Assistant Physician, Craig Colony, Sonoma, N. Y.; Member
New York Neurological Society, etc.

FOR years many competent observers have urged the nervous origin of all asthmas; but some other observers have spoken of the different forms of asthma as having different origins, and admit only the one special form of asthma known as bronchial asthma as having marked neurotic etiological factors. The theory of the neurotic origin of bronchial asthma was first advanced many years ago by Trousseau, while later Bier-

mier proved quite conclusively that a spastic nervous element entered largely into bronchial asthma, which he stated consisted of a tonic spasm of the muscles of the smaller bronchi. Sommerbrodt proved that sudden attacks of asthma were due, in certain cases, to a reflex cause, an irritation applied to the mucous membrane in some area of the respiratory tract. Bert in 1870 showed by experiment that contraction of the medium-sized and finer bronchi was actually produced in a typical manner by irritating the vagus. Probably the one writer, Sommerbrodt, has embraced in his numerous writings all that has been definitely ascertained in regard to the reflex causation of bronchial asthma.

As to however true all these different theories may be, whether we accept a neurosis as the causation, or a direct disturbance of the vagus itself, it is certain that a disturbance of the nerve supply to the bronchi is primarily the most important factor in the causation of the single asthmatic paroxysm.

Not infrequently we see cases of epilepsy that have as a complication, with the defective bodily organization, a condition allied to true asthma. Many young epileptics have these attacks of asthma as a consequence of deformities of the chest. But it is rare to see a case of epilepsy in which a case of asthma has developed long after the epilepsy has been in existence and in which the asthmatic attacks alternate with epileptic fits. Recently one case has been placed upon record showing that asthmatic attacks alternated with true epileptic seizures. The writer desires to place an additional case upon record in which a little different condition exists, which is peculiar and interesting because of the probability of the concomitance of the two diseases in the same case having a common neurotic origin. The case is reported in detail as follows:

The patient is a male; age fifty-eight, single, a common laborer. At the time of his admission to the Craig Colony, May 22, 1896, his epilepsy had been existent but nineteen months. The first epileptic attack occurred in October, 1894, while he was acting as porter in handling trunks in an uptown hotel in New York City. At this time his convulsions were confined entirely to the right side. He did not recover consciousness sufficiently to know his whereabouts until the end of the second day. This attack was attended by loss of speech for several hours, and since then he has never recovered his speech entirely so as to speak as plainly as he did before. He has had but six epileptic attacks since his epilepsy began, and has had no regular seizures since his admission to Craig Colony. At present there is considerable muscular weakness of the right side, which, the patient states, has been present since his first attack. Dynamometer examination showed 75 pounds under grasp of the right hand; left, 85.

Physical examination of the patient shows the following: Marked mitral regurgitation; pulse lacking in force and rhythm; a condition of mild general arterial fibrosis is present; peripheral circulation is poor. A condition of varicosity was found in the lower extremities, and hemorrhagic areas were found in the face and on the arms. The condition of the lungs presented consolidation at right apex; respiration seemed restricted on right side. The hearing is bilaterally defective, most marked on the right side, which, the patient states, was present for a number of years before his epilepsy began. The patient's eyesight is very

defective; cataract is forming in each eye; arcus senilis was found in both eyes. The reflexes of both sides were very active, being little more marked on the right side.

Stigmata of degeneration: Broad, low arched palate; auricles defective and asymmetrical.

The supposed cause of his epilepsy was due to extreme and prolonged intemperance in the use of alcoholic stimulants, although sufficient cause might be found in the condition of the patient's arterial system following right hemiplegia. No evidence of syphilis was obtained. Since the patient's admission to the Colony he has repeatedly had slight temporary attacks of asthma. The paroxysms occur in the early morning hours without any apparent cause. The character of the diet, condition of weather and general physical state give no clue to the occurrence of attacks. During their presence the patient is considerably disturbed; he becomes quite dizzy and is obliged to sit down because of physical exhaustion. The condition seems to be of the nature of *petit mal* attacks, although most of the disturbance is centred in the respiratory tract and manifested mainly by a difficulty of breathing, presenting in some respects the appearance of paroxysms of typical asthma. These asthmatic conditions have not been particularly modified by the administration of potassium iodide. His asthmatic attacks are quite rapidly relieved by temporary inhalations of stramonium taken in the form of cigarettes. The patient states of his own accord that at times he has had periods of slight "confusion and dizziness, attended by difficult breathing." Occasionally he has some slight sensory disturbance, a numbness of the right side.

The case is not dissimilar to other cases of epilepsy occurring in later life, and would call for no special attention if it were not for the peculiar character of the asthmatic paroxysms, which resemble on their mental side *petit mal* attacks of epilepsy.

MASSACHUSETTS GENERAL HOSPITAL. SECOND CLINICAL MEETING OF THE STAFF.

MEETING of February, 1896, DR. C. B. PORTER, President.

TWO CASES OF CERVICAL MYELITIS.

DR. J. J. PUTNAM: I wish to call your attention very briefly to two cases of cervical poliomyelitis. This form of the disease is rather unusual, and the cases show some peculiar features. This affection usually comes on in extreme youth, though occasionally in adult life, and is now considered as probably toxic if not infectious. It occurs in epidemics, as was the case here two or three years ago. The disease began in this young girl when about three years old. Considering that this supposed toxic substance circulates with the blood through the gray matter in which the vessels ramify, it is certainly very remarkable that so little of the cord should be affected and yet that portion affected so severely. One arm is reduced almost to a skeleton. All the movements she can make are below the elbow. We have a marked example of the claw hand and an extraordinary illustration of wrist-drop. The motions of the small muscles of the hand are almost abolished, and the muscles involved are exces-

sively atrophied. A few muscles are preserved, and one must imagine that corresponding to those muscles a few nerve-cells are preserved. The disease is mainly of the upper-arm type, probably for the most part of the shoulder girdle. The lower arm is considerably involved. It is quite interesting to note that these cases sometimes follow the type of atrophy and paralysis seen in so-called obstetrical paralysis of children where the brachial plexus is injured during delivery. In that case the upper arm is especially involved and the lower arm less so, the extensors more than the flexors. The extreme atrophy of one arm which came on in this sudden manner is all that this patient has suffered from hitherto, but of late she has noticed a weakness beginning in the other arm. Whether that will increase we do not know. The left hand shows a slight amount of atrophy between the thumb and forefinger. There is a little excavation, and she has more or less pain there. It may be that this is one of the cases where this acute disease is going to take on a chronic and progressive form of which I will speak later. The knee-jerk on the side of the worst arm is slightly exaggerated. We find almost no reference to this in the books, but it shows that the white columns on the same side with the diseased gray matter are more or less involved from either primary or secondary disease. The disease seems to be starting up again in the form of progressive muscular atrophy, an outcome which is occasionally observed.

The next patient is in the same condition except that the lower-arm muscles are better preserved. He has taken great pains to develop himself, and such muscles as he has are quite strong. Here also the arm hangs almost out of its socket. The whole shoulder-blade is much smaller than its fellow — certainly not more than two-thirds as large — and all the muscles that cover it are much wasted. The knee-jerk is exaggerated here also; and this patient, too, recalls the child with obstetrical paralysis which is due to the pressure on or stretching of the brachial plexus at birth. The sensibility is normal and no other part of the body is affected.

Poliomyelitis, or myelitis of the gray matter, is the name under which this disease has gone. It seems evident, however, from the fact that the knee-jerk is exaggerated that the long motor tracts which run near the gray matter are more or less involved. That is interesting in connection with the view held nowadays by some writers, that progressive muscular atrophy and lateral sclerosis are the same disease; and that the gray matter is involved, the motor columns always more or less affected, whether the disease is acute or chronic.

TWO UNUSUAL CASES OF SKIN DISEASE.

DR. C. J. WHITE: Dr. J. C. White is unable to be here; but these cases, he thought, would be interesting. The three patients are machinists, two of them brothers. A little over two weeks ago this one noticed a few vesicles on the face, which were at first the size of a pin's head. A few days after, this patient, who slept in the same bed, broke out and finally vesicles began to appear upon the face of this man, who is the brother. The cases are very peculiar. It is hard to know how to classify them. They resemble the type of impetigo seen in children more than anything else, but clinically they are very different from that. The principal peculiarity is that the vesicle does not become a pustule, but remains a vesicle or bulla and then subsides. In

making cultures on blood serum from this case, although the bulla was perfectly clear, this marked result was obtained, which I supposed to be a colony of *staphylococcus aureus*, but Dr. Ernst thinks it is a little doubtful, judging from the color.

TOTAL EXCISION OF THE SCAPULA FOR SARCOMA.

DR. J. C. WARREN: I have to present a case of total excision of the scapula for sarcoma. It is the first case, so far as I know, that has ever been done in the hospital. A large portion of the scapula has been excised, but not a total excision.¹

The patient has since been subjected to the antitoxin treatment. The method employed is as follows: the doses are given subcutaneously near the tumor, usually in such cases as this near the seat of operation, and vary from one-half to about ten minims of a filtered antitoxin prepared from the erysipelas antitoxin and antitoxin of the bacillus prodigiosus according to the method of Coley. Filtering the solution apparently takes away considerable sediment, which, when injected, sometimes produces disturbance. The material should be injected about once in three or four days and a reaction of about 102° is desirable. This patient has had the injections about two weeks, and this chart shows the variations of temperature when antitoxin has been injected. On one occasion there was a sharp rise of temperature, a chill, and considerable tumor around the seat of injection. The material was used afterwards, and used the same day on another patient without any trouble whatever. A small subcutaneous syringe with asbestos plug carefully sterilized is used.

An interesting point is that there is a fair amount of use of the arm, although the elbow cannot be raised from the side to any extent. Dr. Cabot has a case like this in a boy of the same age, the same scapula, and also produced by a blow, but a much more formidable tumor. It is a large-cell sarcoma.

ADDISON'S DISEASE AND PNEUMOTHORAX.

DR. F. C. SHATTUCK: I have two patients to show. This patient was sent to me by Dr. James J. Minot. He was at "the Island." Nothing very important in his previous history. He was perfectly well until about six months ago, when he began to get short of breath, and since that time he has had progressive weakness and shortness of breath. There is a general bronzing of the skin with atrophic patches which are not scars. Most of these are pigmentary, but the skin is generally of this dark color. He says he used to be fair. The conjunctivæ are clear. No bile-pigment in the urine. Physical examination is practically negative. The blood-count shows moderate anemia, and there seems to be very little reason to doubt that this is a case of Addison's disease in which the pigmentation is rather more marked than the general symptoms, although there has been notable loss of strength and shortness of breath, for which we find no sufficient reason on physical examination.

Cases of Addison's disease are not very common. I have seen not more than half-a-dozen in the last twenty years. There seems to be no reason to think that this pigmentation is arsenical. He has been living in different places and not long enough in one place to get chronic poisoning. There is no history of acute poisoning, and there is no arsenic in the urine. The pig-

mentation is as marked on the trunk as anywhere else.

The second patient, Mr. A., came from Springfield four weeks ago, with the statement that there was some paresis of both vocal cords, and respiration cut off from the right side. Dr. A. Coolidge, Jr., and others examined him, and found no paralysis of the cord. The respiration was cut off from the right side. The percussion note was tympanitic and the heart displaced to the left, the apex being one and a half inches outside the mamillary line. The history is as follows: A perfectly healthy man except that there is the history of a chancre, but no secondary symptoms. He had a terrible cough, lasting about a month, last summer, following exposure to cold. He said the cough was like whooping-cough. He kept at his work and got over the cough about the first of September. During October he began to be short of breath. The shortness of breath gradually increased until it was so great that he could do very little work. When at rest he was comfortable, but on the least exertion he suffered very much from this symptom. What existed was a rare condition of things, namely, a pneumothorax with a healthy lung. Pneumothorax is not at all uncommon in connection with phthisis; but there is no phthisis, and he has not reacted to the tuberculin test. The case is unusual in two respects: first, that the lung is normal except for this, and, second, the gradual onset. Ordinarily, we can fix the date of pneumothorax, the symptoms are so pronounced. The best explanation that has occurred to me is that the violent cough which he had last summer weakened some portion of his lung and that under exertion he burst a little hole, the air gradually leaking out and the lung contracting more and more, so that when he came to me he had no use of his right lung. I have drawn the air out four times by simply introducing a needle attached to a tube under water so that whatever air comes out passes through the water, its escape being shown by bubbles, and none can go back. At first it comes out with a gush and then only on coughing. I tapped him last two weeks ago yesterday. He is a great deal better. It seems as if the opening was somewhat valvular or else that it is still patent, for when the lung expands a certain amount of reaccumulation takes place. The accumulation has not been as great as before tapping, but each time there is more air a few days after the tapping than immediately afterwards. When he came there was no liver dulness and the apex of the heart was one and a half inches outside the mamillary line. It is still beyond the nipple. He has a narrow liver dulness. On percussion, the difference between the two sides is not very marked. The breath-sounds are still very weak. He has had under the clavicle an amphoric respiration only to be heard by immediate auscultation. It is not present now. It has been a pure pneumothorax, not a pneumo-hydrothorax.

I have seen only one case like this. That was in the servant of a family who are patients of mine. They spoke of her shortness of breath on going upstairs. On examination, I found to my surprise that one side of her chest was full of air. I drew the air out several times and she recovered. I think this patient will recover.

DR. BOWEN: Does Dr. Shattuck know the origin of the scars in the first case?

DR. SHATTUCK: No. The man worked with the sleeves rolled up. I do not think these things on the

¹ See Boston Medical and Surgical Journal, May 21, 1896.

back are scars, certainly most of them are not. They seem to me to be patches of atrophic pigment. Dr. White concurs in that opinion.

DR. BOWEN: Judging simply from the appearance of the skin, it does not seem inconsistent with the long-continued scratching that results from pediculosis. The fact that he has no pediculosis now would not exclude it, because it is only where that has gone on for years and years that you get this condition.

DR. SHATTUCK: That would not affect the face, would it?

DR. BOWEN: It is my impression that cases have been recorded where in vagabond's disease the mucous membrane has been pigmented.

DR. SHATTUCK: Has a case of vagabond's disease been observed in a workingman in this country? This man was working and earning good wages. He went to the Island on account of failure of health and inability to work and support himself.

DR. BOWEN: It seems strange he does not know about these scars.

DR. SHATTUCK: Are they scars?

DR. BOWEN: I should say it was an atrophic process of the nature of scars. As I see him to-night the case is not unlike cases I have seen of that disease.

DR. SHATTUCK: I have never seen a case of vagabond's disease, and I supposed such cases were Austrian or German rarities.

DR. VICKERY: I have asked him about scratching, and he said he never scratched himself.

DR. SCUDDER: Have sections been made of that apparently pigmented skin?

DR. SHATTUCK: No. I am trying to get some adrenals to feed him on, but it is difficult.

A CASE OF CHYLURIA.

DR. VICKERY: This next patient came to the outpatient department last July, when Dr. Ernst saw him and recognized his disease. He is a master carpenter, and works every day. He is well except for this one peculiarity. He is fifty-seven years old. Twelve years ago he was in Florida for a while. About five years ago this passing of white-colored urine came on more or less gradually, and of late years he has passed it every night. The urine clears up with ether. It is a case of chyluria. In the daytime the urine is perfectly clear, and in most examinations has proved entirely free from albumin. Sometimes there has been a little albumin in the daytime, but no evidence of kidney trouble. He can bring on a chyluria by lying down an hour, and more readily if he lies on the back than on the side, so that position would seem to have some influence. The only inconvenience is that the mucus contained in his urine forms clots, and it is hard to get them through the urethra. Sometimes he has to try all day long, when at last a plug will come away affording relief. The way in which this disease is said to be dangerous is by causing emaciation or debility, which has not happened in this case. The filaria sanguinis has been found by Dr. Ernst in his blood. About eight o'clock at night he took the blood from his ear. I had him lie down in the hospital, and have made a number of slides, but have not yet obtained the filaria. What the patient wants is advice about treatment.

DR. CABOT: Is the recumbent posture especially necessary to obtain the filaria?

DR. VICKERY: Not as a rule. They are only found at night, when the chyluria is going on.

DR. CABOT: I once had a patient with lymphscrotum. He came from South America for advice. In that case I examined several times the blood drawn during the day without obtaining the filaria. Finally, I asked his room-mate, who was a medical student, to prick the finger of the patient during sleep about midnight; and in the first slide there were two, and after that I saw several from the blood drawn at night. I supposed there was something really cyclical about it.

DR. VICKERY: There are some unusual cases in which the chyluria occurs in the daytime and not at night. It would seem as if there must be something cyclical.

DR. WARREN: When Mr. Bryant, of London, was here he mentioned two cases of lymphscrotum in which he had performed the operation for phimosis with the result of a cure. These cases he published in the English journals, and the theory was that possibly the organisms resided in the prepuce and invaded the system from that point. The operation was done merely as a palliative operation, but was followed by a cure in these cases.

DR. PORTER: I remember the same statement.

DR. VICKERY: The embryo of the filaria is in the blood. The mosquito gets this by biting a person. It is then deposited in water and develops into the worm, and drinking that water starts the process.

DR. ERNST: I have been interested in studying a number of cases reported in this latitude. There seems to be a marked difference in the number of these organisms that are found in the blood as compared with what are reported as occurring in the tropics. In the cases occurring in India a very large number of filaria are said to be found on each cover-glass, while in my own experience it has been almost impossible to find more than one or two on a cover-glass.

DR. WHITNEY: As I understand it the filariae are entirely innocuous. It is only the parent worm that does harm, and these embryos have no deleterious effect at all upon the individual. When found in the blood they are important simply as a means of diagnosis.

DR. VICKERY: That is true, I believe. One other thing: some cases do not have the chyluria every night as this patient does. They have periods of it, and then it disappears.

MULTIPLE LIPOMA OF THE SKIN, CYSTIC ADENOMA OF SEBACEOUS GLANDS.

DR. PORTER: I wish to present some photographs of multiple lipoma of the skin. The patient entered for stone in the bladder, and on examining we found that he was covered with fatty tumors of different sizes. A point of interest is that he is a miner and works all day naked, and it was suggested that nature had tried to cover him with a layer of fat to protect him but that it was irregularly distributed.

I have also the photographs of a case Dr. Whitney will speak of. The man entered with a family history practically negative. Eight years ago he first noticed the tumor, which was a small lump the size of a melon seed behind the angle of the jaw. This has gradually enlarged. There were no subjective symptoms. The tumor was fully as large as an ostrich's egg, and the one thing noticeable was that for so large a tumor in the parotid region it was quite movable. It was very hard, and seemed to me to be an enchondroma that had undergone more or less calcareous change. I was very much surprised when I cut into it to find a fluid oily

in character, rather sticky and thick, flowed from the small incision I made. This fluid became hard on cooling. The incision was clamped and the tumor, which proves to be a very rare form of disease, was shelled out.

DR. WHITNEY: The tumor is a cystic adenoma of the sebaceous glands. It shows on the inside the peculiar white substance of which Dr. Porter has spoken and which looks as if some one had poured thick cream over the cut surface. When first removed it was fluid, but almost immediately became transformed into this creamy substance on cooling. On microscopic examination it is found to consist of structure, which in character and the shape of the cells correspond exactly with the sebaceous glands of the skin. These showed various degrees of dilatation, forming cysts, some as large as the end of the finger. These lie imbedded in a cellular tissue, part of which is of the nature of the lymph glands, with slight dilatations of the lymphatics in them. This, then, could neither be classed as a wen or a dermoid; the former is a retention cyst of the sebaceous gland, caused by the outlet having been stopped up; the latter, in which is also found sebaceous material, consists of an infolding of the skin beneath the surface into which the sebaceous glands open and pour their contents into the closed sac. The present tumor is a true new formation of sebaceous glands, without any outlet upon the surface of the body, thus growing in an atypical way and forming these retention cysts beneath the skin. As far as my experience goes it is a unique tumor both in size and in the peculiarities of its structure. Dr. Wood has examined the material which comes from the interior of the cyst, and says it is simply fat like human fat and in every way similar to the ordinary sebaceous material formed in abundance in a case of seborrhea.

DR. WARREN: The case of multiple lipoma interested me particularly. One authority has studied the location of lipomata on the surface of the body and has shown, particularly in the case of multiple lipomata, that they develop in those parts of the body that have the least number of sudoriferous glands which need a large amount of fatty tissue for their growth, development and function; and where they are performing their function we do not get an over-accumulation of adipose tissue, but may get over-accumulation of adipose tissue in parts where these glands are less numerous. It would be interesting in this case to see just what the location was. The fact that he works where he is obliged to go without clothing may be considered as stimulating the nutrition of fat over that of sudoriferous glands.

DR. PORTER: On the shoulders and upper part of the trunk, a very common seat for lipomata, he has very few, whereas on the lower part of the trunk, thighs and on the forearms he has many.

DR. WHITNEY showed alcoholic specimens and said: The first specimen is from the scapula Dr. Warren removed.

I wish to call your attention to three specimens of brain tumors, one of which was operated upon, one attempted to be operated upon, and the third was accidentally found at autopsy, being secondary to a primary tumor elsewhere. I will not speak of the clinical side of the cases, but simply show the specimens. The first tumor, which Dr. Richardson removed last May, proved to be a glioma; the patient lived until December, when he suddenly died. The wound in the skull was closed

completely with a fibrous plate beneath which considerable fluid had accumulated. This filled a cavity in the posterior part of the brain communicating with the ventricles. On removing the dura it was found to be more or less adherent over the anterior portion of brain which is seen to be involved in this large growth, occupying the whole of the temporal and frontal lobes, leaving only a portion of the occipital lobe intact, and yet, if I remember rightly the statement of the attending physician, the man, who was completely aphasic, had driven himself in his carriage the week before his death.

Medical Progress.

REPORT ON PROGRESS IN THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M.D., BOSTON.

THE CONTRIBUTIONS OF BACTERIOLOGY TO THERAPEUTICS.

DR. WILLIAM HALLECK PARK in his abstract¹ of the Wesley M. Carpenter lecture delivered October 21, 1897, has presented this subject so admirably that the reporter desires to direct the attention of the readers of the JOURNAL to his statement. Dr. Park begins by saying it is now well known that bacteria cause diseases chiefly by means of the poisons which are elaborated during their growth. The abstraction of food from the body and the mechanical interference with functions which are caused by their presence are also deleterious, but in a minor degree. Although many complex factors influence the degree of susceptibility of the body to infection from any pathogenic germ, the most important and perhaps all-embracing one is whether or not the animal organism at the time and place of infection is in proper condition for the growth and activity of the invading germ. The living body is not a good soil for most bacteria, even after they have penetrated the outer protecting wall of skin and mucous membrane.

The protection against infection exists in different degrees in the same individual toward different bacteria and among different individuals toward the same bacteria. The causes of immunity, either natural or acquired, are still only partially understood. If a few virulent anthrax bacilli are injected into a susceptible animal, the results of inoculation are soon manifest and death of the animal follows. If an animal of the same species, which has previously been immunized, be inoculated with the same germ, the bacilli not only do not increase but soon die. It was found, when seeking the reasons for this varying action of the bacteria, that in non-immunized animals they develop unhindered by the vital activity of the cells or fluid substances of the body, while in the immunized animals certain cells are attracted by the bacteria, and eventually destroy them. Metchnikoff's recent investigation of the pneumococcus infections would seem to show that the attraction of the leucocytes for bacteria is not wholly due to any inherent property of the leucocytes but rather to the effect upon the leucocytes of substances in the serum.

As a working hypothesis it may be considered that a toxin is a substance which is directly poisonous according to the intensity of its affinity for the cells of

¹ Medical News, November 6, 1897.

the living body. The cells of a chicken which can tolerate enough tetanus toxin to kill thirty horses, but which can be affected by still larger doses, may be considered to have 10,000 times less attraction for the toxin than those of the horse. If it is further considered that the toxin even has a stronger affinity for the antitoxin than for the cells, it may be understood how, this affinity being satisfied, the poisonous power is neutralized, and it can no longer injure the cells. Dr. Park states that in his opinion an antitoxin may be best conceived as a toxin which has been changed by contact with the living cell, either within the cell or outside of it.

An important characteristic of antitoxins is the fact that they are gradually eliminated from the blood by the urine, saliva, etc., so that after a few weeks they may have entirely disappeared. As the nature of micro-organisms which cause small-pox, etc., is not known the immunity which follows their occurrence is naturally not clearly understood.

Bacteria differ greatly as to the particular tissues in which they can develop, and, therefore, in the manner in which they produce infection. For instance, a few tetanus bacilli introduced by a splinter into the foot multiply but slightly, but find the soil suitable for the production of sufficient toxin to kill within a few days. The same bacilli introduced into the body by way of the alimentary canal, although readily developing in the intestines, find no lodgment in the mucous membrane, and are, therefore, harmless.

There are certain general factors which temporarily affect the susceptibility or resistance of the living tissues to all micro-organisms. Thus, clinically, as well as bacteriologically, it is known that lack of food, exposure to heat and cold, over-exertion, extreme youth, old age, and many other influences predispose to disease, while opposite conditions assist the body to protect itself.

In order to determine whether curative agents are produced for any individual disease, it is necessary to examine in each, by means of the toxins, or by living cultures, whether immunity may be produced in an animal, and whether in such an animal the blood contains at any time sufficient antitoxin, or bactericidal properties, to confer immunity when introduced into the bodies of other animals. It must further be decided in each individual disease what length of time may elapse from the date of the infection in which the serum or toxin will still be able to prevent the development or arrest the progress of the disease.

Tetanus antitoxin has been applied on a large scale in immunizing animals against possible infection. For instance, horses used for the production of antitoxin serums run a considerable risk of tetanus infection from the large number of hypodermic injections which are necessary. The Health Department lost several valuable animals in this way; and since then the experimental animals are immunized from time to time with 30 c. c. of tetanus antitoxin, with the result that tetanus does not occur. The results of treatment with tetanus antitoxin are not so brilliant as are those of immunization. By the time the symptoms of tetanus are manifested the cells are frequently too profoundly affected to receive any assistance from the antitoxin. The symptoms of this disease develop from one to five days after infection. Judged by a study of the statistics of 31 acute cases developing within eight days and 40 cases of long incubation and

slow onset of symptoms antitoxin seems to have positive curative effect in the less acute cases of tetanus. As it is impossible to tell at the outset which cases will be benefited, it seems wise, in conjunction with the usual treatment, to administer the antitoxin in doses of 20 to 50 c. c. twice daily in all cases of tetanus, and to begin the treatment at the earliest possible moment.

Diphtheria antitoxin is singled out among antitoxins by the success which has attended its employment in the treatment of diphtheria, as vaccine is among immunizing procedures in the prevention of small-pox. The great mass of physicians are convinced that diphtheria antitoxin in doses of 200 to 300 units will confer immunity against diphtheria from two to four weeks and that the period may be lengthened at will by repeated doses. By this means many children's asylums are now kept free from diphtheria. They believe further that when cases are seen early, that is, before general poisoning has occurred, antitoxin may be relied upon to arrest, with but very few exceptions, the progress of the disease.

Tetanus and diphtheria antitoxin, although so nearly identical in their efficacy as agents for immunization, differ greatly in their curative value. The explanation of this is the manner in which the two infections begin and progress. The tetanus infection progresses from five to ten days undetected in the wound, but only after general poisoning has occurred is the disease manifested to the observer. The diphtheria infection starts on the surface and before its toxins are fully developed and absorbed it is diagnosed.

The nearest approach to the powerful tetanus and diphtheria antitoxin is that of the plague bacillus. This with the toxins produces in immunized horses a serum which is distinctly antitoxic and bactericidal. In man the serum has been used in several hundred cases, and given beneficial results both for purposes of immunization and cure, the mortality having been lowered from an average of 80 to 50 per cent.

The serum of animals immunized to streptococcus and pneumococcus toxin and cultures possess bactericidal and antitoxic properties, but of much less power than the plague serums, and the discovery that it rapidly deteriorates accounts for the fact that practically all of the preparations on the market are valueless.

The serum of animals immunized to tuberculosis is also extremely weak in bactericidal and antitoxic substances.

The new tuberculin of Koch requires improvement before it can be advised for practical application. Experiments show that most of the cells contain living tubercle bacilli which are capable of causing tuberculosis in animals. It is too early to judge of the therapeutic value of the new tuberculin, but with an improved technique it should be furnished free from bacilli.

Typhoid fever and cholera may be classed together. Animals may be immunized to both, and their serum will be found to contain feeble antitoxic and moderate bactericidal properties.

No form of micro-organism has yet been found in the brain or spinal cord of men or animals attacked by hydrophobia; nevertheless, it is certain that one exists, for the disease is readily transmitted from animal to animal. The preventive treatment instituted by Pasteur has been subjected to great criticism, but Dr. Park believes the efficacy is finally established. The immunizing value of the Pasteur treatment has been

tested experimentally in the Research Laboratory of the Health Department of New York City, and though these experiments are not yet complete they present striking evidence that the injections do produce immunity, and that when properly carried out they are without danger even in very susceptible animals.

The results of the use of vaccine virus in the prevention of small-pox are almost universally accepted. The serum of vaccinated animals contains very feeble curative properties, too feeble for practical use.

The outlook in the future is bright for obtaining through serums, or through the toxic substances of the micro-organisms themselves, means for immunizing against most, if not all, of the bacterial diseases. This immunity in most instances will not be of long duration, but the difficulty may be overcome by repeating the immunizing injection. When the micro-organisms that cause scarlet fever and measles and the other diseases in which a prolonged immunity follows recovery from infection the hope is that vaccine as efficient as that now used in small-pox may be obtained. The prospect of obtaining serums that will promptly arrest the progress of a disease by the destruction of the micro-organisms and their poisons already in the body is not so encouraging as it at one time appeared.

The serum procured from animals immunized by the pneumococcus has very slight curative power, but sufficient has been accomplished to make further investigation imperative and to justify physicians in using it in the treatment of cases of pneumococcus infection.

The hope for the future is that all growth of the micro-organisms may be stopped and further action of the bacterial poisons be prevented at the moment the treatment begins; but it cannot be expected that the tissue-cells or the activity of the organs will be benefited except by neutralizing certain deleterious products, thus allowing the vital processes and other therapeutic aids a better chance of success.

A FATAL CASE OF POISONING BY CHLORATE OF POTASSIUM.

Dr. Paul Jacob² presents this case in detail: The patient entered the hospital in a comatose state thirty hours after she had taken chlorate of potassium—it was learned later she had purchased about 25 grammes of this drug—and improved very much, but died suddenly on the sixth day of heart failure. During her illness examinations of the urine and careful blood examinations were made which showed the effect of the drug on these two fluids. The writer closes by saying that chlorate of potassium should be used neither as an internal medicine nor as a gargle. The latter use should be especially avoided for children, as they are apt to swallow some of the fluid when gargling. Many articles show that chlorate of potassium, even in small doses, is a strong blood poison, and even if death does not ensue a hemorrhagic nephritis very frequently results.

KOCH'S TUBERCULINS.

A Berlin correspondent³ says it will take years to really decide the therapeutic value of the new serum. The use of the old tuberculin for diagnosis seems to be disapproved in the clinics for internal medicine here. The reaction which occurs after its injection when tubercle bacilli are present is thought to be due to a

necrosis of tissue around the bacilli and the absorption of toxic products therefrom. This necrosis may cause the further absorption of bacilli into the lymph- or blood-vessels and so institute an acute process. The majority of people have encapsulated bacilli in the apices of the lungs or somewhere in the bronchial glands without being at all tuberculous, therefore the reaction cannot be said to be definitely diagnostic of active tuberculosis. In cases where the bacilli are prevented from doing any harm by the barrier of inflammatory lymph there is danger that the quiescent condition may become active under the influence of the injected toxins. The injections are considered practically unjustifiable except in such serious affections as pleurisy or ascites, where the patient's dangerous condition makes an experimental diagnosis with tuberculin less to be feared.

ON TAPPING THE PERICARDIUM, WITH REPORT OF TWO SUCCESSFUL CASES.

Austin Weldon, F.R.C.S.I.⁴ states that at present just one hundred cases of paracentesis pericardii have been recorded, although probably many more have occurred. Out of all these cases only once has the operation been fatal. In this unsuccessful case the right ventricle was lacerated by the trocar. Some others have died soon after the operation, but these were cases that were moribund at the time it was undertaken. The remainder were without exception relieved and many of them cured. Experience, too, has shown that the operation is not attended with great danger and certainly in cases of effusion from rheumatic pericarditis there is every prospect of recovery.

Mr. Weldon's first patient was a woman fifty-eight years old; the effusion was evidently increasing and as death seemed imminent the pericardium was tapped. When eight ounces of a dark-colored fluid had been withdrawn the flow was very slow, the instrument was therefore taken out and the wound covered with flexible collodion. As the patient appeared faint a little brandy and ammonia were administered. An hour later all difficulty of breathing had disappeared, but although the patient expressed herself as completely relieved, a very slight cyanotic condition remained. On the following morning this was gone, and her pulse was strong and regular. She left the hospital five weeks later in perfect health.

The second case was that of a man twenty-six years old and was evidently of a rheumatic nature. As death seemed imminent also in this case the pericardium was tapped and almost immediately the patient's breathing was improved. Several hours after the operation the pulse was 100, the temperature 100°, respiration 24. Cyanosis, dyspnea and epigastric distress had completely disappeared. The fluid, unlike that of the previous case, was a healthy serum. Two days later the pains in the knees returned but were readily relieved.

Mr. Weldon speaks of one more case that occurred in the practice of Dr. Redmond; 22½ ounces of dark-colored fluid were removed, and seven days later 27½ ounces. A drainage-tube was subsequently inserted. This case recovered perfectly.

The writer closes by quoting Dr. Samuel West's conclusions in an article in the "Medico-Chirurgical Transactions."

(1) Paracentesis pericardii is not only justified, but

² Medical News, October 23, 1897.

³ Berliner klin. Woch., July 5, 1897, No. 27.

⁴ Medical Press and Circular, December 16, 1896.

an operation which may be safely undertaken with ordinary precautions. One case only is recorded in which the operation was fatal. With this exception all the patients were greatly relieved by the removal even of a small amount of fluid, and many recovered completely who would probably have died if the operation had not been performed.

(2) The most suitable place for puncture is, in ordinary cases, in the fifth left intercostal space one inch from the edge of the sternum, but if the pleura be adherent, the puncture may be made safely much farther out, and even in the sixth space.

(3) The instrument employed should be a trocar and canula, with or without aspiration.

(4) The operation may be performed with advantage not only in the pericardial effusion of rheumatic or primary origin, but also those which occur in the later stages of general dropsy, if it should appear that the fluid in the pericardium is adding to the difficulties under which the heart is placed.

(5) Purulent pericarditis is best treated on general principles like an empyema. (a) The pericardial sac may in these cases be safely opened and drained. (b) The treatment, moreover, appears to be the only one which offers the slightest hope of recovery. (c) The results are likely to be more favorable than those of empyema, for the walls of the cavity are better able to contract rapidly and thus permit of complete obliteration.

THE CAUSATION OF CHLOROFORM SYNCOPE.

Leonard Hill, M.B.,⁵ in a valuable address delivered before the Society of Anesthetists, London, February 18, 1897, on the results of an experimental inquiry carried out by himself with the assistance of Harold Barnard and C. Wall of the London Hospital, concludes as follows:

(1) Chloroform produces a primary failure of the circulatory mechanism and a secondary failure of the respiratory centre. The respiratory centre fails to act not only because it is damaged by the drug, but because of the anemia of the spinal bulb produced by the fall of arterial tension. This is proved by the fact that the action of the respiratory centre can be renewed by raising the arterial tension.

(2) Chloroform, more than any other agent, rapidly abolishes the vascular mechanisms which compensate for the hydrostatic effect of gravity.

(3) Chloroform abolishes these mechanisms by paralyzing the splanchnic vasomotor tone, and by weakening the action of the respiratory pump. When these mechanisms are totally abolished the circulation is impossible if the subject be in the feet-down position.

(4) Chloroform also produces paralytic dilatation of the heart. It acts directly like amyl nitrite on the musculature of the whole vascular system.

(5) There are two forms of chloroform syncope. (a) During primary anesthetization, the patient struggles, holds his breath, raises the intrathoracic pressure, congests his venous system, lowers his arterial tension and finally takes deep inspirations and surcharges his lungs with chloroform. In the first stage the left heart becomes impoverished; in the second stage it is suddenly filled with blood. This is drawn from the lungs and is full of chloroform. The chloroform passes into the coronary arteries, and the heart is thrown into paralytic dilatation. Respiration and the pulse either

cease simultaneously, or the pulse before respiration. (b) During prolonged anesthetization this arises from gradually giving chloroform to too great an extent. The arterial pressure falls lower and lower, and, secondarily, the respiration ceases because of the anemia of the spinal bulb. The heart is not in this case paralyzed by chloroform, because the drug is taken in gradually by the shallow respiration, and distributed slowly by the feeble circulation.

(6) Artificial respiration and the assumption of the horizontal position, if applied in time, will always resuscitate a patient from the second form of syncope.

(7) Artificial respiration, established with the patient in the horizontal posture, is also the treatment indicated in the first form of syncope; the heart should be rhythmically compressed by squeezing the thorax. If this does not quickly renew the pulse, the patient should be put into the vertical feet-down posture. The dilated right heart is thereby completely and easily emptied of blood. Artificial respiration is maintained during this manœuvre, and the patient is brought once more into the horizontal posture. By rhythmic compression of the chest an efficient circulation is maintained through the coronary arteries, by first emptying and filling the heart a fresh supply of blood is brought into that organ. If this does not prove successful on the first trial it can be repeated.

(8) Inversion, that is, placing the subject in the feet-up position or compression of the abdomen will increase the paralytic dilatation of the heart. In this kind of syncope both these forms of treatment are worse than useless.

(9) In the condition of shock or emotional fear the compensatory mechanism for the effect of gravity is almost abolished, and chloroform may easily be the last straw to completely paralyze the circulation.

(10) Vagus inhibition of the heart is of no importance as an agent in the production of chloroform syncope.

(11) Ether is in every respect a far safer anesthetic than chloroform. According to Ringer's experiments on the heart, ether is fifty times less dangerous than chloroform.

(12) With the practical conclusion of the Hyderabad Commission that the chloroform inhaler should be removed during the struggling of the patient or when the respiration is of irregular depth, I am in absolute agreement, but I consider their interpretation of their own experiments and tracings concerning the origin of chloroform syncope to be mistaken.

Not only the work of all physiologists, but also the tracings of the Commission when rightly interpreted, prove that paralysis of the circulatory mechanism, and not of the respiratory centre is to be dreaded by the anesthetist.

THE THERAPEUTICS OF THE INTERNAL SECRETIONS.

Dr. Francis P. Kinnicutt⁶ presents in this paper the various theories which have been deduced from experimental, pathological, and clinical observations of the functions of the ductless glands, together with a review of the results of therapeutics in their various diseases, based upon such theories.

The Typhoid Gland.—Dr. Kinnicutt discusses its office and then goes on to say that in myxedema the

⁵ British Medical Journal, April 17, 1897.

⁶ American Journal of Medical Sciences, July, 1897.

symptoms are speedily removed by the treatment but that a discontinuance of this is certainly followed by a return of the myxedema at varying intervals, showing that the treatment does not cause the gland to resume its function, but exercises its influence by introducing into the economy something which it is presumably the function of the gland to supply. It has been shown conclusively, first, that complete recovery can be effected even after the disease has existed for as long a period as fourteen years and in the case of patients bed-ridden and presenting the gravest symptoms; and, secondly, that the maintenance of health can only be secured by continuous treatment during the life-time of the patient.

Cretinism, Sporadic and Endemic.—Continued experience during the few years which have elapsed since the treatment of cretinism with thyroid preparations was first instituted has confirmed the hopes which were originally entertained of its efficacy. It has been shown conclusively, first, that in sporadic cretinism the myxedematous symptoms can speedily be removed, thereby effecting a marvellous improvement in the frightful deformities incident to the disease; secondly, that the treatment is capable of developing the natural tendencies of the growth of the skeleton which were in abeyance, and this latent capacity is in inverse ratio to the age of the patient; thirdly, that a striking improvement in the mental condition is effected, although occurring more slowly and in a similar inverse ratio to the age of the patient, as observed in the skeletal growth. In the case of a girl of eighteen years of age at the beginning of treatment, the growth was four and three-quarters inches in the first year of treatment, two and three-eighths in the second and one and three-eighths in the third.

As the child approaches the height normal at a definite age continuous growth apparently is only at the usual rate. In the very rapid growth of the bones a tendency to softening, resembling that which occurs in rickets, has been noted by several observers and has been ascribed to the use of doses of the thyroid extracts, which were probably too large.

Already cases of cretinism in children have been reported where the intelligence after three years of treatment has compared favorably with that of normal children of a similar age.

The therapeutic value of thyroid preparations in cretinism has suggested their use in cases of idiocy more or less resembling in bodily or mental defects the cretinous condition. Bourneville has shown that the weight of the thyroid gland varies very considerably in different cases of idiocy. Telford Smith has tried the treatment in idiots belonging to the Mongol type, who most closely resemble the cretin. His experience has been that a physical and mental improvement occurs, and that it is inversely to the age of the patient; that the improvement is neither so rapid nor so marked as in the cretin.

Goitre.—The benefit derived from the use of the thyroid preparations in cases of goitre in which the absence of constitutional symptoms indicates that the function of the thyroid gland is still largely preserved consists in a retrogression of the goitre through atrophy of the hyperplastic and adenomatous tissues. Recurrence of the tumor after partial or complete disappearance, at varying intervals after the discontinuance of the treatment, certainly occurs in many instances, and suggests the possibility that continued use

of the thyroid preparations in a modified way for indefinite periods may be found necessary.

Bruns has reported 60 cases, non-malignant and non-cystic in character treated by this method; 14 were cured, 29 improved and 17 were not benefited by the treatment. Knœpfelmacher reports 21 cases. In 11 of these the retrogression of the goitre was marked but in none was it completely removed. Nine of these 11 cases were of the hyperplastic type. In five cases of colloid goitre the tumor was diminished in size, and in the remaining cases no improvement was observed. Augerer has treated 78 cases. The most striking results were noticed in the soft goitres of the simple hyperplastic form and especially in those occurring about the age of puberty. In 83 cases of Stabel's, improvement was obtained in 92 per cent.; in two only was there unquestionably permanent recovery.

In explanation of the action of the thyroid-gland preparations in goitre, Bruns, Ewald and others have suggested the hypothesis of a primary toxemia of unknown origin, which invokes an increased functional activity of the gland, accompanied by hypertrophy. If the demand for thyroid products is supplied artificially, the gland retrogrades and atrophy results.

Exophthalmic Goitre.—The natural fluctuations of the disease, improvement alternating with recrudescence, suggest that the exceptional reports of improvement under this treatment have been based upon insufficient grounds.

Insanity.—The use of thyroid preparations in the treatment of various forms of insanity was originally based upon its undoubted power to increase ultimate cell-metabolism. A relatively large number of cases treated by this method have been published.

Bruce believes that the action of thyroid in insanity is a complex one:

- (1) That the feverish condition induced by it is of benefit to the patient.
- (2) That it acts as a direct cerebral stimulant.
- (3) That it supplies some material necessary to the recovery which the gland is supplying in insufficient quantity.

The results of this treatment indicate a decided advance in the therapeutics of certain forms of insanity.

Obesity.—The number of published cases in which the thyroid treatment has been used during the past four years is large, and the results in general have been favorable.

Cutaneous Diseases.—The expectations originally entertained of the value of thyroid treatment in diseases of the skin have not been fulfilled.

Phthisis.—The suggestion of the possible value of thyroid preparations in phthisis rests on the slender basis of their temporary effects in some cases of lupus, upon the assumed antagonism of goitre and tuberculosis, and, finally, upon the atrophy of the thyroid gland in chronic wasting disease.

The Adrenals.—With the exception of Tizzoni's notable experimental investigations, from which he concludes that the adrenals are functionless and derive their importance from their anatomical relation to the sympathetic, all modern work strongly indicates that they are functionally active glands.

Dr. Kinnicut discusses the two theories in regard to the nature of their function, and then says that he has collected 48 cases of Addison's disease treated with various adrenal preparations. Six patients are reported as cured or practically well, 22 improved, though

later some of these died, 18 unimproved, and in two instances an aggravation of the symptoms is stated to have occurred during treatment.

Thymus Gland.—The determination of the true physiological position of the thymus gland in the human economy is especially difficult on account of the several histological phases in its natural history.

In judging of the therapeutic value of the thymus treatment in exophthalmic goitre too much reliance should not be placed upon the relative number of published cases of successes and failures. Favorable results from a new remedy are more frequently reported than failures. The natural fluctuations of the disease are great, and improvement and recrudescence occur often in an inexplicable manner.

Goitre.—In 20 cases reported by Mikulicz complete cure in the anatomical sense was only obtained in two cases, but in twenty cases the goitre was reduced in size.

Pituitary Body.—As in the case of the glandular structures already considered, the function of the pituitary body is variously believed to be of a secretory or excretory nature. In a few cases of acromegaly the administration of pituitary extract was found to relieve certain of the characteristic symptoms.

Dr. Kiuncut closes with tabulated reports of the use of adrenal preparations in Addison's disease in about 50 cases, of thymus therapy in exophthalmic goitre in 62 cases, of pituitary treatment of acromegaly in 13 cases.

Recent Literature.

Tuberculosis of the Genito-Urinary Organs. By N. SENN, M.D. Philadelphia: W. B. Saunders. 1897.

The author reminds us in his preface that there has been a gap in the medical literature on this subject, and it has been admirably filled by him with this work.

In the opening pages the belief is expressed that, in a fair percentage of cases, the male genital organs are the primary seat of tuberculosis, the bacilli reaching these organs through the general blood circulation, and being deposited and reproduced there without discoverable tubercular lesions existing elsewhere. The cases that occur in this way are but a small proportion of the whole number in which tuberculous disease involves the genito-urinary organs, the larger part being those in which the process is primary in other parts of the body and appears in these organs as a secondary infection.

A number of well-attested cases are reported which give proof of the existence of primary tuberculosis of the penis. Tuberculosis of the urethra is mentioned as occurring, but as being exceedingly rare. The spermatic cord is stated never to be the primary seat of the disease. Occasionally the disease originates in the seminal vesicles, but more often it is here secondary to its presence in other parts of the genito-urinary tract.

Gueillot and Broca are quoted as having found examples of seminal vesicles transformed into calcified or fibrous masses, the final result of a preceding tubercular process. Several cases of removal of one or both vesicles are given, and brief reference made to the operations which have been devised for this purpose.

Fenger's case is the most notable of these instances. Primary tuberculosis of the prostate is next considered, but there is little if any post-mortem evidence brought forward to sustain the idea that it occurs. Brief reference is made to the treatment of the disease as it affects the prostate, both radical and palliative measures being enumerated.

Part II deals with the disease as it appears in the epididymis and testicles. The author quotes the opinion of Councilman—with which he agrees—that fifty per cent. of uro-genital tuberculosis has its starting-point in the epididymis. The infection may extend from the kidney downward to these organs, but when the testis is affected, it has generally begun in the epididymis. The infection is noted as beginning most frequently in the globus major of this organ.

The symptoms of the disease as affecting these parts are well set forth, and the chapter concludes by a description of the treatment, in the course of which the contraindications to castration are stated as follows:

(1) Extension of the tubercular process to parts not within reach of a radical operation; (2) tuberculosis of both testicles, as the second testicle is usually involved by the extension of the infection from one to the other through the vasa deferentia; (3) tuberculosis of important adjacent or distant organs. Some interesting observations of what seem to have been examples of the prevention of general extension of the disease to other organs, owing to timely castration, are also given.

The palliative treatment is described at the close of the chapter, the two measures most commended by the author are injections of iodoform glycerine emulsion, or of chloride of zinc, and in cases of limited abscess-formation curetting, and iodoform gauze tamponing.

Chapters III to VIII inclusive, which constitute about one-third of the book, are devoted to tuberculosis of the female organs of generation. The liability to error in diagnosis is considered to be much greater here than in cases of tubercular lesion of the male genitals. Confusion is especially likely to occur with regard to cancer.

The evidence for and against the belief that tuberculosis is more or less frequently primary in the female genital organs, as well as that of their invasion by it from the peritoneum, or *vice versa*, and evidence of its being imparted by coitus is set forth, the disease is then considered in detail as it manifests itself in the various organs of the female genital apparatus. Many interesting observations illustrate this part of the subject. Statistics are quoted which indicate that tubercular lesions of the female genital tract increase the frequency in proportion to the distance from the introitus vaginae, the vulva being the least, the Fallopian tubes the most frequently affected parts.

Some of the cases which furnish proof of the contention that vaginal tuberculosis may be established by coitus are given, amongst them eight reported by Derville which are especially conclusive.

The last part of the book is devoted to the consideration of renal tuberculosis, which is treated with the same thoroughness that marks the whole work.

The volume is fully and well illustrated. It is in all respects worthy of its author, who has thus added another to the number of valuable contributions to medical literature from his pen.

A Manual of Legal Medicine. By JUSTIN HEROLD, A.M., M.D., formerly Coroner's Physician of New York City and County, late House Physician and Surgeon of St. Vincent's Hospital, New York City, etc. Large 8vo, pp. 678. Philadelphia: J. B. Lippincott Company. 1898.

The author in his preface says: "In preparing it the writer makes no pretensions to originality, nor does he profess to be giving information that is entirely new; but he does claim that he has prepared a book of medium size in which the attempt has been made not only to embrace the contents of the more elaborate and classic works, but to present them, together with original material hitherto unpublished, condensed into a comparatively small, but not too scant, space."

As a compilation, the work is, as a whole, a success; and presents in a fairly compact form, a large variety of matter that should be of interest and value to the student and practitioner. His claim, however, that "in the present volume everything that is practical and useful has been inserted, and all idle and superfluous questions which are still *sub judice* are dispensed with," is hardly borne out by the facts.

Certain portions of the book, and especially the examples and explanations, are not so clear as one would wish them to be; but, as a whole, the matter is clear cut and well arranged.

In Part First, something over one hundred and thirty pages are devoted to Toxicology, a rather too large amount of which is given up to the pure chemistry of the subject, when but so few pages are allotted to so large a subject. The unfortunate effects of the various embalming fluids upon the tissues, from a medico-legal standpoint, is well shown, and attention directed to the importance of enacting laws to control this, in many instances, unfortunate practice. Nothing is said, however, of the equal importance of providing some penalty for those who, with or without reason, break such laws.

Part Second, Forensic Medicine, is on the whole well arranged, and in a form which makes those points upon which information is most frequently sought, easy of access. It contains many tables, well arranged and classified, which are of very considerable value.

The chapters on Medico-Legal Autopsies, Personal Identity, and Examination of Blood Stains are worthy of special note, and show that a large amount of time has been spent in their arrangement.

The final chapter is one of Pharmaceutical Jurisprudence, by George F. Roesch; and it presents in a few pages the legal position, liabilities and duties of the pharmacist in the State of New York, in a clear and satisfactory manner.

Diseases of the Eye and Ophthalmoscopy. A Handbook for Physicians and Students. By DR. A. EUGEN FICK, University of Zürich. Authorized Translation by ALBERT B. HALE, A.B., M.D., one of the Ophthalmic Surgeons to the United Hebrew Charities, Consulting Ophthalmic Surgeon to Charity Hospital, Chicago, etc. With a Glossary and 158 Illustrations, many of which are printed in colors. Pp. 488. Philadelphia: P. Blakiston, Son & Co. 1896.

This book is a translation of the manual published in 1894 by Dr. Fick. The publishers have done their duty to the work, both in letterpress and illustrations.

The first part of the book is devoted to methods of examination. These are worked out from a theoretical point of view with great care, and the American editor has supplied such muscular tests as are in common use in this country at the present time. Retinoscopy seems to have been forgotten, however, by both the author and American editor.

The second part, devoted to Diseases of the Eye, covers ground usually treated in hand-books of this class in the customary manner.

The therapeutics, while good, have scarcely been brought up to date, as for instance, there is no mention of the expression of trachomatous follicles or of the success of the treatment of diphtheritic conjunctivitis with antitoxin.

The Physiology and Pathology of the Cerebral Circulation. An Experimental Research. By LEONARD HILL, M.B., Hunterian Professor, Royal College of Surgeons; Lecturer on Physiology, London Hospital Medical College, etc. Pp. 206. London: J. & A. Churchill. 1896.

The volume before us is the substance of three lectures, delivered by the author as Hunterian Professor at the Royal College of Surgeons. The title clearly indicates the scope of the work, which is chiefly of an experimental sort. It is divided into three sections, entitled respectively, "Pulsations of the Brain," "The Cerebro-Spinal Fluid," and "The Cerebral Circulation." The last section occupies the bulk of the volume, and discusses in a most painstaking way various matters relating to this, in many ways, obscure subject.

Appended to the volume is a good bibliography. In short, the book is an excellently presented and concise expression of existing opinion, admirably printed and bound, and one which may be cordially recommended.

The Physician's Visiting List. (Lindsay and Blakiston's, for 1898.) Forty-seventh year of its publication. Philadelphia: P. Blakiston, Son & Co.

This excellent visiting list appears for the year 1898 in the same compact and convenient form as before. The dose tables, comparisons of weights and measures, etc., while complete, are very compact and well arranged for quick reference. Simplicity and thorough adaptation to the purpose for which it is intended characterize the book throughout.

Vita Medica: Chapters of Medical Life and Work. By SIR BENJAMIN WARD RICHARDSON, M.D., LL.D., F.R.S. Pp. 495. London: Longmans, Green & Co. 1897.

Those who are familiar with the admirable work of Sir Benjamin Richardson will welcome this copious volume, giving so intimate a description of his personal and professional life. It will be found of interest to all who look upon medicine seriously; and we recommend it to those whose work permits of an occasional leisure hour for reading not strictly professional.

A Treatise on Gynecology, Medical and Surgical. By S. POZZI, M.D. Translated by BROOKS H. WELLS, M.D. Pp. 936, 600 illustrations. New York: William Wood & Co. 1897.

The second American edition of this well-known text-book is a translation from the third French edition. It is only necessary to say of so standard a work that this third French edition has been brought thoroughly to date, and differs from its predecessors only in this fact.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 16, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.**THE PROPOSED YELLOW FEVER COMMISSION.**

THE recommendation embodied by the President in his message to Congress that a commission be appointed to investigate yellow fever is a timely one, and should be acted upon. Medical science has made great strides in recent years, and the failure of former commissions should have no weight at this time. As the greatest nation on this continent, we should regard it our duty to make an effort to find means to restrict a plague of such far-reaching influence upon the commercial interests of the continent.

In view of the probability that such a commission may be put at work, the question arises, Will such a body limit its labors to weighing the claims of Sanarelli's *Bacillus icteroides* or the bacillus x of Sternberg, or will it take a broader view of its task? Assuredly both these organisms will receive due attention, for the indefatigable labors of Sanarelli have piled up a mass of experimental work which naturally enough would form a convenient point of attack for the commission's work. Similarly the laborious and cautious work of Dr. Sternberg on the bacillus x needs re-examination in view of Sanarelli's discovery.

The *B. icteroides* appears to be closely related to the colon group, more particularly to its many pathogenic derivatives affecting animal life with which we are now familiar. There is nothing peculiar or uncommon about it. The tests upon animals prove it to be an invasive rather than a toxic organism. The effect of the culture filtrates on man is claimed by Sanarelli to closely simulate yellow fever; we must be cautious, however, in interpreting these symptoms due to toxius, for many of them have appeared in cases of poisoning by bacteria in foods.

It has been shown that the serum-test is applicable for diagnostic purposes not only in typhoid and cholera, but in several animal diseases caused by motile bacteria. The *B. icteroides* responds, as the discoverer himself states, very slowly when mixed with serum from convalescents. The fact observed by him, that

in the blood of persons treated with the toxin of the *B. icteroides* agglutinative properties appear, does not prove that this organism is the cause of yellow fever.

Other criticisms might be made theoretically invalidating Sanarelli's main conclusion, but we simply content ourselves with the further statement that the organism does not seem to fit the disease.¹ But if it should prove to be the true cause, the commission would still have before it the pathological and epidemiological relationships to fathom. Why should a bacillus of such characters be suppressed by frosts? Why should it not be transmissible from person to person?

How does it gain its fearful momentum so promptly in the body? The commission may find, as has been experienced so frequently in the recent past, that the discovery of the microbic cause of a disease is but the first, though perhaps the most important, step in the complete elucidation of the etiology. Ulterior steps may be as arduous and perplexing as the first.

If, on the other hand, these organisms should turn out to be secondary invaders, the commission will have the whole subject fresh before it, and for this possibility the members should be prepared. The modern methods of etiologic research demand a division of labor if anything is to be accomplished. This labor should be directed by an acknowledged leader in whose hands the information acquired day by day may be used to gradually mould the working hypotheses in conformity therewith. Whatever may be the outcome of the commission's work in regard to the infectious agent, something clear and definite would be expected from it on the nature of the disease process, the quality of the immunity attained after an attack, the specific channels of infection and better methods of diagnosis. If one or the other of the bacilli mentioned is found to be the specific cause, these problems will demand industry and application rather than genius.

Such a commission should, therefore, be composed not of "bacteriological experts" only, unless this word signifies more in the language of the President's message than should be attributed to it. It should embody, in addition the training of the bacteriologist, that of the pathologist, that of the physician thoroughly conversant with the chemical laboratory methods of clinical medicine, and that of the epidemiologist conversant with the highways and byways of infectious agents. A commission thus constituted would be prepared for unexpected developments, and we should probably not feel disappointed with the product of its labors even though the specific microbe should continue an unknown and elusive organism.

TREATMENT OF FRACTURE OF THE PATELLA.

THE treatment of fracture of the patella (and in this article we shall confine ourselves to recent, simple, transverse fractures, such as are obtainable by a fall

¹ Dr. Sternberg's bacillus x belongs evidently to the same group; but in its pathogenic properties it is quite unlike Sanarelli's bacillus, being toxic rather than invasive.

on a curb-stone) by any of the non-operative methods is slow and tedious. Bony union is hindered by contraction of the quadriceps tendon, which keeps the fragments apart, by intrusion between the fragments of the torn patella aponeurosis, by effusion of blood between the two fragments and into the joint. So difficult in fact is it to maintain the fragments in juxtaposition, that ligamentous union only can be expected in these cases.

It would be a tedious task to enumerate all the appliances which have from time to time been devised to force the fragments into contact, from figure-of-eight bandages and straps to Malgaigne's hooks and Boye's special trough and plaster-of-Paris splints. A long rest of six or eight weeks in bed in a retentive apparatus is required, after which passive motion is permitted, in spite of which some stiffness of the joint often remains. Professor Hamilton states that at the end of four weeks in favorable cases the patient may be allowed to get up on crutches; in six or eight weeks the bond of union may be considered as completed, but the danger of rupture of the ligament is so great that for the next three or four months the patient should walk on crutches with the knee well supported by an inflexible splint secured by straps and buckles. "For six months at least, the patient is incapacitated from using his limb and its motions are likely to be impaired for life."¹

The surgeon who undertakes to treat this fracture by any of the non-operative procedures must take care lest harm be done by misdirected zeal, through too much pressure on the patellar fragments by which the circulation is impeded, and by a tilting forwards of the broken edges of the fragments causing a troublesome deformity. Dr. William Anderson, of St. Thomas Hospital, England, is so impressed with the danger of mischievous interference that he declares that "simple rest and extension of the limb without any attempt to coerce the fragments of the broken bone into position afford the best prospect of sound union." And that it is perhaps to the exclusion of such interference that we are to attribute the success claimed in recent years for the innocent expedient of massage of the extensors.²

Successful wiring of the fragments in broken patella was one of the early triumphs of antiseptic surgery, and when Lister in 1880 first performed the operation under carbolic spray he only carried out those principles which had already given brilliant results in operations on the great cavities of the body. Lister correctly reasoned that the new doctrine — *no microbes, no suppuration*, was as applicable to the knee-joint as to any other part, and that one antiseptic case would exclude pus-microbes in any cutting operation on the knee-joint; and consequently the principal danger apprehended from such operations would be removed. Thence to the institution of free drainage in exudative inflammations of the knee-joint was an easy step; and wiring the fragments of a broken

patella seemed the most sensible and expeditious way of treating a lesion which had long been a *bête noir* to the surgeon. By the method of wiring, bony union might now be obtained and much time saved to the patient who in six or seven weeks' time could be about his work with a firm patella and a good joint. Dr. Ward of London treated three cases of fractured patella, one by apparatus, and two by wiring; in the first the total time lost before resuming work was twenty-seven weeks, and in the two that had been wired, thirteen and eight weeks respectively. He further states that the first could not kneel until nine months, while the other two could do so six and five weeks after the operation.³

If the results of wiring the patella for fracture had been uniformly successful, this would long ago have been everywhere the method of election by the highest surgical authorities. Unfortunately, in a certain proportion of cases where rigid sepsis was attained or seemed to be attained, suppuration and subsequent ankylosis or even death has followed. Conservative surgeons were alarmed at these accidents, and declared that wiring ought to be abandoned. In some quite modern treatises on surgery, wiring is still spoken of as an operation which the surgeon should hesitate to perform. In the sixth and last edition (1896) of the *Dictionnaire de Médecine et de Thérapeutique* by Bouchut and Désprès, the operation of wiring as a mode of treatment in patella fractures is not as much as mentioned. Notable papers have continually been published in favor of non-operative treatment, and some have sought to avoid the dangers of the open method of wire-suturing by subcutaneous wire-suture through the patella, as performed by Ceci, the subcutaneous silk-suture through the tendon of the quadriceps and the ligamentum patellæ as performed by Stimson. Chaput reports successes obtained by silk suture of the fibro-periosteal covering of the bone; mediate suture by silk passed through the tendon of the quadriceps and the ligamentum patellæ after incision. Anderson, of London, passes two stout pins transversely through the skin and the tough anterior fibrous envelop of the bone, and then by pressure upon the projecting ends of the pins draws the fragments together. Barker, of London, passes a silk ligature longitudinally beneath the bone, entering it through the ligamentum patellæ and bringing it out through the tendon of the quadriceps and then between the skin and patella to the point of entrance, where the knot is then tied and the ends cut short; but it would be tedious to enumerate all the methods devised to escape the supposed dangers of the open method, and we may say of these subcutaneous devices (with Stimson) that they expose to the chance of infection and suppuration almost, perhaps quite as much as the open incision does.⁴

It would appear that of late the method by open incision and wiring of the fragments has grown in favor with leading surgeons throughout the world, though it has not quite received the sanction of the

¹ International Clinics, October, 1891, p. 121.

² London Lancet, July 2, 1892, p. 10.

³ International Clinics, 1891, October number.

⁴ Sajous' Annual, 1893.

profession at large. We find surgeons in the country and in private practice still treating fracture of the patella largely by the old methods, while in the metropolitan hospitals where the best antiseptic care is attainable surgeons are more and more preferring the operative treatment. It is probable that not all cases are suitable for operation; cachetic and the alcoholic subjects should be eliminated.

Many surgeons, as Dr. Stephen Smith, Dr. Lucas-Championniere, and Dr. Charles Phelps (the latter reports as a definitive result in forty-two cases bony union in forty-one of the number) do not hesitate to wire in all cases of simple fracture in healthy individuals; others as, Von-Bergmann and König,⁵ still protest against the use of the suture in simple fracture. It may be said to be a truth that most persons to whom time is precious would prefer for themselves the operation by suture provided they could be treated by a competent surgeon. Professor Lister who introduced the operation gives an excellent rule for the guidance of the surgeon: "No man is justified in performing such an operation unless he can say with a clear conscience that he considers himself morally certain of avoiding the entrance of any septic mischief into the wound."

Only a considerable operative experience and the control of trained assistants can give the surgeon sufficient confidence in his asepsis to justify him in suturing the patella. The modern surgeon who possesses these advantages has in the method of suture, a means of greatly diminishing the temporary and permanent disability which follow this fracture.

ON THE FREQUENCY OF PLURAL BIRTHS.

PRACTITIONERS with a large experience in obstetrics, and organizations which are in the habit of making collective investigations of births, have noted the fact that in proportion as the numbers of births under investigation increase, so much the more does the frequency of plural births approach a uniform ratio. In Massachusetts, for a period of forty years (1856 to 1895), this ratio is found to be a little less than one per cent. for twins, or more accurately, .92 of one per cent., and a little more than .01 of one per cent. for triplets, or more accurately, .013 of one per cent. Stating the question otherwise, there were 109 living births to each case of twins in the whole period, and 9,626 births to each case of triplets. In proof of the remarkable uniformity in the occurrence of triplets in long periods of time, it was found that there were 9,623 living births to each case of triplets in the first twenty years (1856-1875), and 9,629 living births to each case of triplets in the second twenty years (1876-1895).¹

These figures are the result of observation upon over 1,750,000 births which occurred in Massachusetts in the forty years (1856-1895).

¹ Erroneously stated as 12,292.7 in the Registration Report of 1895.

⁵ Congress of International Surgery, 1896.

In proof of the uniformity of occurrence of these events when still larger numbers are considered, and for other countries, the following figures are presented:

RATIO OF PLURAL BIRTHS TO EACH 1,000 BIRTHS.

	Twins.	Triplets.
Switzerland	12.2	0.12
Prussia	12.2	0.13
Bavaria	12.4	0.15
Austria	11.7	0.15
Italy	12.1	0.15
France	9.8	0.11
Sweden	14.4	0.17
Massachusetts	9.2	0.13

The foregoing table presents the results of observations upon twenty million births in the countries named. (See Vital Statistics of Massachusetts for Forty Years, in Twentieth-annual Report of the State Board of Health, Boston, 1897.)

MEDICAL NOTES.

RUSSIAN MEDICAL SCHOOL FOR WOMEN.—The newly established medical school for women at St. Petersburg, recently opened with 165 students.

A PROFESSORSHIP OF TROPICAL DISEASES.—A chair of "tropical diseases," with Dr. J. E. Stubbett as the first incumbent, has been established in the New York University Medical College.

A NEW ADULTERATION.—The Department of Agriculture has discovered that many creameries are using an emulsion of cottonseed oil, which, added to the cream, increases the butter product per gallon of milk, with small chance of detection and a large increase of profit. — *Medical Record*.

AN INFIRMARY FOR CORNELL UNIVERSITY.—Mr. Dean Sage and Mr. William D. Sage have given to Cornell University the house of the late Henry W. Sage for a University Infirmary. They also endow the institution with \$100,000 and will equip the building for a hospital, the total value of the gift being \$200,000.

PHRENOLOGIST AS AN EXPERT.—For the first time in the history of the criminal courts of the State of Missouri, or probably of any State, phrenology has been recognized as a science in determining insanity. On the 13th inst., in a murder trial before Judge Zachritz, a phrenologist was permitted to qualify as an expert and testify as to the insanity of the defendant.

VETO OF THE GEORGIA ANTI-FOOTBALL BILL.—Governor Atkinson, of Georgia, has vetoed the Anti-football Bill with the sensible remark that "it would be unfortunate to entirely suppress in our schools and colleges a game of so great value in the physical, moral and intellectual development of boys and young men."

AN ASEPTIC BARBER SHOP.—An aseptic barber shop, probably the first in America, has been established by Emile Caye at the Carrolton Hotel, Baltimore, Md., according to the *Yale Medical Journal*. Everything about the shop is sterilized. The shaving cups, combs, brushes and razor handles are made of aluminum, which is the metal that best stands steril-

ization. The hands and arms of the barber as well as the head and face of the customer are also made aseptic.

FOREIGN PHYSICIANS IN ITALY.—According to recent telegraphic reports from Italy, quoted in the *British Medical Journal*, a deputation sent by the English doctors in Rome to the Italian Home Office, to inquire as to the intentions of the government with regard to the demand of the Italian National Medical Congress for a law obliging foreign doctors to undergo a State examination, was cordially received and informed that for the present there was no danger of such a law being passed.

SMALL-POX IN GEORGIA.—It is reported that small-pox prevails in thirty counties in Georgia. The epidemic in Atlanta will cost the commercial interests of the city over \$1,000,000 during the holiday season alone. Compulsory vaccination here has had the effect of frightening the country people away from Atlanta. In Atlanta there have been 120 cases of small-pox, but no deaths. According to a report in the daily papers, Col. E. E. Cavaleri, a veteran of the Union army, seventy-four years of age, has sued the city of Atlanta for damages. When the city physicians were recently making their vaccination rounds, Colonel Cavaleri's *fiancée*, objected to vaccination, saying she was about to be married. The doctor told her it was better to be vaccinated than married, and persuaded her to be vaccinated. When Cavaleri came next to see her, she told him she had decided to follow the doctor's advice, and refused to marry him; hence the suit for damages.

BOSTON AND NEW ENGLAND.

SCARLET FEVER IN NEWTON.—Two primary schools in West Newton have been closed by order of the Local Board of Health, owing to the occurrence of about twenty cases of scarlet fever among the pupils.

THE NEW ENGLAND HOSPITAL.—The New England Hospital for Women and Children celebrated its thirty-fifth anniversary on September 30th. A new dispensary building, the gift of Col. A. A. Pope, has been opened this year.

FINED UNDER THE MEDICAL REGISTRATION LAW.—In the Municipal Court at Boston recently, Judge Ely fined Augustus R. Gilmore \$200 for styling himself a "doctor" on his cards. The defendant claims to effect cures by the laying on of hands. He appealed and was held in \$500 bail for the upper court.

FIRE AT DEER ISLAND HOSPITAL.—The easterly wing of the hospital building at Deer Island, Boston Harbor, was damaged by fire on December 11th to the extent of \$6,000. The fire was due to the overturning of a gasoline lamp, and demonstrated the insufficiency of the water-power on the island. There were no casualties among patients or attendants.

THE AMERICAN ASSOCIATION FOR THE STUDY AND CURE OF INEBRIETY.—The twenty-seventh annual meeting of the American Association for the

Study and Cure of Inebriety was held last week, under the presidency of Dr. Lewis D. Mason, in the hall of the Washingtonian Home, on Waltham Street. Dr. T. M. French, of Milford, read a paper on "The Prognosis of Inebriety." Dr. C. H. Shepard, of Brooklyn, N. Y., spoke on the "Treatment of Inebriety by Baths." Dr. T. D. Crothers, of Hartford, Ct., read a paper on "The Insanity of Inebriety." Dr. I. N. Quimby, of Jersey City, N. J., spoke on "The Use of Alcohol in Practical Medicine." The other speakers were Dr. T. M. Kellogg, of Battle Creek, Mich., and Dr. Ira Van Gieson, director of the New York State Pathological Institute, who spoke on "Recent Researches into the Action of Alcohol on Brain Cells." The following officers were elected for the ensuing year: President, Lewis D. Mason, Brooklyn, N. Y.; First Vice-President, Isaac T. N. Quimby, Jersey City, N. J.; Second Vice-President, J. W. Grosvenor, Buffalo, N. Y.; Third Vice-President, James T. Searcy, Tuscaloosa, Ala.; Fourth Vice-President, J. T. Eskridge, Denver, Col.; Fifth Vice-President, Henry J. Hall, Franklyn, Ind.; Secretary and Treasurer, T. D. Crothers, Hartford, Ct.

DEATH OF A CENTENARIAN.—Mrs. Marinda Gifford died in New Bedford December 11th, aged one hundred years and four months.

DR. MAXFIELD SUCCEEDS DR. McLEOD.—Dr. George A. Maxfield, of Holyoke, Mass., has been appointed by Governor Wolcott a member of the Board of Registration in Dentistry, in place of Dr. E. U. McLeod, secretary, of New Bedford, deceased.

TWO CITY PHYSICIANS AT SALEM, MASS.—An ordinance has been adopted by the Salem Board of Aldermen providing for two city physicians, instead of one, as now. The city is to be divided into two districts, and the salaries are to be \$500 each instead of \$750 for one, as now.

BIRTHDAY OF A CENTENARIAN.—Mrs. Lydia C. Tenney, of West Concord, N. H., celebrated her one hundred and second birthday recently. She was born in Bradford, Vt., and was married in 1816. Of nine children she has one living, Daniel C. Tenney, seventy-five years of age.

NEW YORK.

A PROTEST AGAINST APPROPRIATIONS FOR HOSPITALS.—As a meeting of the Board of Estimate and Apportionment held December 7th, the Executive Committee of the Manhattan Branch of the Medical League of New York, the new Protective Physicians' Association, appeared to protest against the appropriation of public moneys, which is discretionary with the Board, towards the support of such institutions as the Sloane Maternity, the Post-Graduate Hospital and the Homeopathic Hospital. The fundamental purpose of these hospitals, it was urged, was not the dispensation of charity, but to afford opportunities for clinical study. The students paid tuition fees, and it was asserted to be a needless waste of the public funds for the city to put additional money into

the hands of such institutions. It was furthermore contended that while the per capita expense of patients in the children's wards of the City Hospital was only 27 cents a day, it was \$1.01 in the babies' ward of the Post-Graduate Hospital, and as high as \$1.53 in some other institutions. A test vote in the Board showed that three of the five members, including the mayor, were in favor of the appropriations, and they were accordingly made. Among the larger sums voted to charitable institutions were the following: New York Foundling Asylum, \$303,717; New York Juvenile Asylum, \$118,250; Hebrew Orphan Asylum, \$100,000; Nursery and Child's Hospital, \$75,000; Children's Aid Society, \$70,000; St. John's Guild, \$30,000.

THREE OF A KIND AND A PAIR. — The wife of a poor tailor living in a rear tenement house down-town on the east side, on December 7th, gave birth to triplets, three healthy boys, whose combined weight was nineteen pounds. Two days afterward she is reported to have been delivered of two other children, both of which were still-born. The mother, who is twenty-eight years of age and had previously had two children (one of which is three years old, and the other one year) is said to have passed through the trying ordeal in excellent shape and to be now on the high road to recovery.

DEATH OF DR. VAN HÖVENBERG. — Dr. James O. Van Høvenberg, a retired physician of Greeridge, Staten Island, died on December 9th of apoplexy, at the age of eighty. He was a son of the late Dr. Henry Van Høvenberg, who was at one time Health Officer of the Port of New York.

A VERY LOW MORTALITY RATE. — Dr. Roger S. Tracy, Register of Records, reports that the number of deaths in the city during the eleven months ending November 30th was 35,790, as against 38,803 for the same period of 1896. The death-rate for these months of 1897 has been 19.6, while the corresponding rate for 1896 was 21.9. The annual rate for 1896 was lowered during December from 21.9 to 21.5, and if we assume that the number of deaths in December of this year will be the same as in December of 1896, the annual rate for 1897 will be 19.4, a mortality so low as to be without precedent. To what extent an estimated population is a factor in this low death-rate we cannot definitely decide.

Miscellany.

QUOD SCRIPSI.

THE following interesting extract is from the *British Medical Journal*:

"What I have written I have written, and neither I nor you nor anybody else can read it." That is the burden of an amusing paragraph in *Truth* on doctors' prescriptions. There is a good deal of *Truth* in it, and we are sorry to say a little truth too. Doctors write abominably, and we do not wonder that in many cases chemists are puzzled. It is the same cause, we suppose, which leads

a man usually to write his own name and address worse than any other part of his letter, to the tribulation of editors and others. He writes them so often that he gets a habit of shortening the process by a hieroglyphic, which is perfectly plain to himself, and which is quite illegible to other people. But as for the chemist, who said he made out what he could and "guessed the rest," we are afraid that the chemist's young man was endeavoring, kindly but mistakenly, to amuse the poor lady who made the inquiry.

A second paragraph consoles the public by reflecting that luckily it does not much matter, for that faith is the main agent in cure. A friend of *Truth's* had an excellent prescription which he had always believed to be, and always found to be, a specific for rheumatism. Some ruthless critic pointed out that it was only a mild tonic, and it never cured his rheumatism after that. This sad, sad story is so true to life, that we suspect *Truth* of inventing it. It states wittily one of the commonest and most inapplicable things in the whole world. Many who fancy they suffer can be brought to fancy that they do not. That is perhaps more wonderful than it seems. But many, whose sufferings depend upon real and irremovable causes, can be relieved if they can be made to believe that the treatment will do them good. The person who inspires the belief may be a doctor, may be a friend, may be themselves. Some absurd theory of the nature of their illness leads them to take Mattei's blue electricity, or something equally efficacious, and behold they are cured. Faith was defined by the little girl at the Board School as "the power of believing things which you know not to be true." Luckily for human nature, man is a persuadable animal even in Northampton.

Correspondence.

A VISIT TO THE HIGHEST METEOROLOGICAL STATION IN THE WORLD.

AREQUIPA, PERU, S. A., November 13, 1897.

MR. EDITOR: — In these days of high mountain climbing, data as to the physiological effects of high altitudes are rapidly becoming numerous, but it may interest the readers of the *JOURNAL* to learn something of the writer's recent experiences in visiting the highest meteorological station in the world, especially as this station was established and is operated by the Harvard College Observatory.

The establishment of an astronomical and meteorological observatory at Arequipa, Peru, and of the seven other meteorological stations which are now operated in connection with it, was the result of a bequest left to the Harvard College Observatory in 1887 by the will of Mr. Uriah A. Boyden. The terms of the will were that the money should be used in establishing an observatory "at such an elevation as to be free, so far as practicable, from the impediments to accurate observation which occur in the observatories now existing, owing to atmospheric influences." Owing to the remarkable clearness and steadiness of the air at Arequipa, it was decided, after a careful study of the meteorological conditions in other places, that the permanent observatory should be located here, and the buildings were erected in 1891. Arequipa is situated about eighty miles from the Pacific Ocean, in Lat. 16° 22' S., Long. 71° 22' W., and about in the middle of the long desert belt which stretches along the west coast of South America from Lat. 4° S. to 30° S. Over all this region rain-fall is either entirely lacking, or is extremely small, and the almost complete absence of clouds during nine months of the year, as well as the clearness of the air, combine to make Arequipa a remarkably favorable spot for astronomical work.

Within the past few years meteorology has made very rapid advances towards becoming a more exact science, largely because of the records that have been obtained at

considerable elevations above the earth's surface. In these higher strata of the atmosphere, at altitudes up to ten miles and more, important movements occur, a knowledge of which is essential to a proper understanding of atmospheric processes as a whole, as well as to the improvement of our daily weather forecasts. The importance of an exploration of the upper air has led to the establishment of meteorological stations on high mountains, such as Pike's Peak, Mont Blanc and the Sonnblick; to the use of small balloons, sent up with self-recording instruments but without aeronauts; and to the elevation of meteorographs by means of a line attached to several kites, the kite work done at Blue Hill Observatory, near Boston, being by far the most successful yet carried on anywhere in the world.

The small snow-fall and comparatively high temperatures on the mountains of Peru, offer exceptional opportunities for the establishment of meteorological stations at great altitudes, and since 1892 Harvard has had the credit of maintaining, in Peru, the highest meteorological station in the world. In that year a station with ordinary and self-recording meteorological instruments was placed, at an elevation of 16,650 feet, on Charchani, an extinct volcano 20,000 feet high, situated twelve miles north of Arequipa. The exposure of the instruments, however, was not favorable, owing to the fact that the station was in a somewhat sheltered position on the flank of the mountain, and in October, 1893, Prof. Solon I. Bailey, then in charge of the Arequipa Observatory, succeeded in establishing a new station on the summit of the Misti, a quiescent volcano, ten miles northeast of Arequipa, at an altitude of 19,200 feet above sea level. This station is about 3,500 feet higher than the one on Mont Blanc, and is therefore the highest meteorological station in the world. The station on Charchani was abandoned after the establishment of the new one on the Misti. The latter mountain offers extremely favorable conditions of exposure for the instruments. It is an isolated volcanic cone, of surprising symmetry, and the atmospheric conditions at its summit are as nearly like those of the free air as it is possible to attain on a mountain. Since its establishment, the Misti station has been regularly visited by the observers from Arequipa, at first, and for many months, once in ten days, and since then about once a month. On these visits the clocks of the self-recording instruments are rewound, the record sheets changed, and check readings of all the instruments are made.

The writer has twice visited the Misti station during a stay of three months in Arequipa, and on both occasions had some personal experience of *soroche*, or mountain sickness. In fact very few persons who have been to the summit have escaped the unpleasant symptoms of this sickness in some of its forms. The trip from the observatory to the top and back occupies two days and is accomplished entirely on mule-back. The start from the observatory (8,050 feet) is made early in the morning, and the night is spent in a hut at the base of the Misti, at an altitude of 15,700 feet above sea level. This is very nearly the height of Mont Blanc. The ascent from the hut to the summit occupies about four hours, the descent to the hut about an hour and a half, and the ride back to Arequipa, five hours more. It is, of course, an extremely fortunate circumstance that no physical exertion need be made in the ascent, for if persons unaccustomed to climbing at high altitudes were obliged to go on foot up the mountain, they would doubtless suffer very severely from *soroche*. The mules that make the ascent all suffer more or less from shortness of breath, and near the summit they refuse to move more than about twenty feet or so without stopping to get their breath. As a rule, however, they stand the strain remarkably well, and have, on several occasions when grass was taken to the summit, eaten at the altitude of 19,200 feet with the greatest apparent relish. Some of the mules belonging to the observatory have made the trip to the summit more than fifty times.

The writer's first ascent was made on October 7th, and was his first experience at a greater altitude than 9,000

feet. At the height of 14,400 feet, where it was necessary to walk about 300 feet, slightly up hill, to visit the instrument shelter, he was obliged to walk slowly, and even then got quite out of breath; but no considerable effects of the altitude were noticed until after the arrival at the hut, at the altitude of 15,700 feet. Here the slight exertion of dismounting from the mule and walking into the hut brought on a violent headache; and the feeling of exhaustion was so great that any exercise, even of the most trifling character, seemed impossible. The writer was obliged to sit down at once, and could scarcely exert himself sufficiently to unpack the lunch basket, in order to take out the supplies for supper. A feeling of nausea — usually the first, as it also is the most common, symptom of mountain sickness — came on very soon, and the mere thought of eating was distasteful. However, after some delay, and by the use of considerable will power, a cup of hot milk and two soft-boiled eggs were disposed of, but it was found impossible to eat anything more. The night was passed in tolerable comfort, although the cold was so great that it was necessary to sleep with all one's clothing on, in an ulster and felt boots, and wrapped up in a sheepskin sleeping-bag. Headache, a feeling of nausea, and quickened respiration, were the only unpleasant symptoms noted during the night.

The following morning the headache was much improved, but the feeling of exhaustion and of nausea continued. The only food that could be taken was hot milk and an egg. The ride to the summit was accomplished without the appearance of any further unpleasant symptoms, but on the summit itself the feeling of complete exhaustion and of weakness was so great that for an hour and a half the slightest exertion was out of the question, and the writer was obliged to lie stretched out flat on the ground. There was some tendency to faintness during this time, and the headache and nausea continued. In a little less than two hours it was found possible, with great exertion, to change the sheets of the self-recording instruments, which were taken from and returned to the shelter by the guide, the writer remaining seated on the ground during the operation, as he found it impossible to lift the large-size barograph, weighing perhaps ten pounds, up into the shelter. When the time came for the descent, after two hours and a half spent on the summit, it was found necessary to have assistance in mounting the mule. At the hut, which was reached in two hours, the instrument shelter — placed about 300 feet from the hut, and about 75 feet higher up the mountain — had to be visited; and on this short walk, two stops in order to take breath were necessary, and anything but a very slow walk was out of the question. The change to a lower altitude was, however, noticeable in a decrease in the feeling of exhaustion, but the headache and nausea continued for some two hours more, on the return ride. Although provided, on this trip, with clinical thermometers and with a sphygmograph, the writer felt so miserably that he made very little use of these instruments. His temperature at 5.30 P. M., October 5th, twelve hours before leaving Arequipa, was 98.4°; his respiration 24, and pulse 90; on the summit his temperature was 96.4°, respiration 34, and pulse 110; and twelve hours after arrival at Arequipa, at 10.30 A. M., October 8th, the figures were 98.0°, 24 and 85 respectively. A rather unsatisfactory sphygmograph curve was obtained on the summit.

The second expedition to the Misti was made on November 9th, and on this trip the writer suffered much less from mountain sickness than on the first. He was able, immediately after reaching the hut at 15,700 feet, to walk to the instrument shelter, although two stops on the way were necessary, as before. An hour after taking this exercise the pulse was 128; the temperature 97.0°, and the respiration 30, the corresponding figures twelve hours before leaving Arequipa being 91, 98.6° and 20. On this trip there was much less exhaustion than on the previous one — in fact, all the symptoms of *soroche* were less marked. It was possible to walk in the hut without great exertion; there was much less feeling of nausea, and considerable appetite. The night was passed comfortably, except

for the cold, which was very disagreeable. Supper and breakfast consisted of hot beef-tea and milk biscuit.

In the morning, immediately after waking up, the temperature of the body was 96.2°, pulse 112 and respiration 30. On the summit the writer felt fairly well when lying down, but the exertion of walking even a few steps brought on a feeling of exhaustion and nausea, and increased his headache. Otherwise he felt well, and even had considerable appetite, although it would probably have been impossible to eat much, even had there been any food at hand. Twenty minutes after reaching the summit the temperature was 97.2°, pulse 120 and respiration 32. In an hour and a half the respiration was 35, the pulse and temperature remaining the same. In two hours the temperature was 96.8°, pulse 112 and respiration 34. Three fairly good sphygmograph curves were obtained on the summit, not without considerable difficulty, however; and these curves, together with one obtained at the hut, at the altitude of Mont Blanc, it is hoped to reproduce at some future date. These curves, so far as the writer knows, are with one exception the only ones ever secured at so great an altitude as 19,200 feet. In counting the pulse on the summit it was quite unnecessary to place the finger on the wrist, as the heart-beats could plainly be heard. The descent was begun two hours and a half after reaching the top. At the hut, after again walking to and from the shelter, the pulse was 130, but the respiration had decreased to 30. One hour after arrival at Arequipa the temperature was 98.2°; pulse 116; respiration 22, and twelve hours after arrival the pulse had fallen to 82—about the writer's normal at the observatory—and the respiration to 22, the normal being 20.

While the ascent of the Misti is a very easy one, and is not for a moment to be compared with the difficult climb up such mountains as Aconcagua or Mont Blanc, the altitude is so great that a study of the physiological effects it produces is interesting. The present writer fared very well—better, in fact, than most of those who have made the ascent. One of the former assistants at the observatory made the trip more than fifty times, and never experienced any discomfort, and one gentleman was so well on the summit that he was able to smoke there. These, however, are the exceptions. Almost every one has headache, nausea, and a feeling of intense weakness; and many experience faintness. Recently an Englishman who made the trip for the first time fainted when part way up, and fell off his mule. The experience of the native guides, who are of mixed Spanish and Indian blood, is very striking in contrast to that of foreigners. These natives are usually able to walk all the way to the summit from the hut without any difficulty, and feel as well on top as they do at the base.

Very truly yours,

ROBERT DEC. WARD,

Instructor in Climatology, Harvard University.

ACTINOMYCOSIS HOMINIS.

953 MADISON AVENUE, BALTIMORE, MD.

December 7, 1897.

MR. EDITOR:—Will you permit me to make use of the JOURNAL to obtain information concerning the occurrence of *actinomyces hominis* in America.

I have collected all the published cases, and feel sure that other cases have been observed. I shall be grateful for full notes on these cases.

In addition to the general description, I should like to know at what time the organism was observed, what the medical and surgical treatment was, and the result.

I should also like any notes on cases already published where further developments have occurred.

Of course, full credit will be given to the observer when the collected cases are reported.

Very sincerely,

JOHN RUHRÄH, M.D.,

City Hospital, Pasteur Department.

METEOROLOGICAL RECORD

For the week ending December 4th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 1,662; under five years of age 483; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 178, acute lung diseases 233, consumption 188, diphtheria and croup 84, diarrheal diseases 29, typhoid fever 24, scarlet fever 15, measles 13, cerebro spinal meningitis and erysipelas 5 each, whooping-cough 3.

From scarlet fever New York 13, Boston and Cleveland 1 each. From measles New York 11, Cincinnati and Cleveland 1 each. From cerebro-spinal meningitis New York and Somerville 2 each, Worcester 1. From erysipelas Boston 2, New York, Cambridge and Haverhill 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending November 27th, the death-rate was 20.2. Deaths reported

4,258; measles 218, diphtheria 97, whooping-cough 70, fever 70, scarlet fever 58, diarrhea 39.

The death-rates ranged from 11.0 in Cardiff to 28.8 in Sunderland; Birmingham 20.3, Bradford 16.5, Brighton 12.0, Gateshead 18.6, Leeds 22.7, Leicester 16.4, Liverpool 23.2, London 21.0, Manchester 20.1, Newcastle-on-Tyne 20.1, Nottingham 17.7, Oldham 28.2, Salford 22.5, West Ham 17.7, Wolverhampton 19.1.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 4, 1897, TO DECEMBER 10, 1897.

Leave of absence for four months, from the date of his departure from Fort Keogh, Mont., is granted CAPTAIN MADISON M. BREWER, assistant surgeon.

Leave of absence for one month is granted CAPTAIN WILLIAM O. OWEN, assistant surgeon, Fort Bayard, N. M.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FOURTEEN DAYS ENDING DECEMBER 9, 1897.

MURRAY, R. D., surgeon. To assume command of Camp Fontainebleau, Miss., in addition to other duties. December 3, 1897.

VANSANT, JOHN, surgeon. Upon being relieved from duty at Wilmington, N. C., to proceed to Charleston, S. C., and assume command of Service. November 30, 1897.

AUSTIN, H. W., surgeon. To rejoin station at Boston, Mass. November 26, 1897.

PECKHAM, C. T., passed assistant surgeon. Upon being relieved from duty at Detroit, Mich., to proceed to Vineyard Haven, Mass., and assume temporary command of Service during absence on leave of Passed Assistant Surgeon W. J. S. STEWART. December 7, 1897.

GLENNAN, A. H., passed assistant surgeon. To report at Bureau on or about January 5, 1898, for temporary duty in Hygienic Laboratory. December 2, 1897.

BROOKS, S. D., passed assistant surgeon. To assume command of Port Townsend Quarantine on or about December 26, 1897, in addition to other duties. December 3, 1897.

WHITE, J. H., passed assistant surgeon. To assume charge of post-epidemic disinfection in Mississippi. December 1, 1897.

MCMINTOSH, W. P., passed assistant surgeon. Relieved from duty at St. Louis, Mo., and directed to rejoin station at Louisville, Ky. December 1, 1897.

MAGRUDER, G. M., passed assistant surgeon. Granted fifteen days' extension of leave of absence on account of sickness. December 1, 1897. Upon expiration of sick leave to proceed to Memphis, Tenn., and assume command of Service. November 27, 1897.

WOODWARD, R. M., passed assistant surgeon. To proceed to Philadelphia, Pa., and report to commanding officer of that station for temporary duty. December 7, 1897.

COBB, J. O., passed assistant surgeon. Relieved of command of Camp Fontainebleau, Miss. December 3, 1897. Upon being relieved from duty at New York, N. Y., to proceed to Detroit, Mich., for duty and assignment to quarters. December 7, 1897.

WERTENBAKER, C. P., passed assistant surgeon. Upon being relieved from duty at Delaware Breakwater Quarantine, to proceed to Wilmington, N. C., and assume command of Service. November 30, 1897.

SMITH, A. C., passed assistant surgeon. To report at Bureau on or about January 5, 1898, for temporary duty in Hygienic Laboratory. December 2, 1897.

YOUNG, G. E., passed assistant surgeon. Granted leave of absence for two weeks on account of sickness. November 29, 1897. Upon expiration of sick leave to proceed to Delaware Breakwater Quarantine Station and assume command of Service. November 27, 1897.

STIMPSON, W. G., passed assistant surgeon. Upon being relieved from duty at Port Townsend Quarantine Station to proceed to St. Louis, Mo., and assume temporary command of Service. December 2, 1897.

STEWART, W. J. S., passed assistant surgeon. Granted leave of absence for one month from December 22, 1897. December 7, 1897.

GARDNER, C. H., passed assistant surgeon. To assume temporary command of Cape Charles Quarantine Station on December 14, 1897, in addition to other duties. December 1, 1897.

CUMMING, H. S., assistant surgeon. Upon being relieved from duty at Philadelphia, Pa., to proceed to New York, N. Y., for duty and assignment to quarters. December 7, 1897.

GREENE, J. B., assistant surgeon. To report to chief of Revenue Cutter Service for assignment as medical officer on Revenue Steamer "McClulloch." November 27, 1897.

GRUBBS, S. B., assistant surgeon. To proceed to New York, N. Y., for duty and assignment to quarters. November 27, 1897.

RUSSELL, H. C., assistant surgeon. Upon being relieved from duty at New York, N. Y., to proceed to Boston, Mass., for duty and assignment to quarters. November 27, 1897.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The Section for Obstetrics and Diseases of Women will meet at 19 Boylston Place, Wednesday, December 22, 1897, at 8 P. M.

Papers: Dr. Sarah E. Palmer, "Report of Five Cases of Hysterectomy for Fibroids."

Dr. Theodore C. Erb: "Cæsarean Section."

F. W. JOHNSON, M.D., Chairman.

C. H. HARE, M.D., Secretary.

BOOK THIEVES.

MR. EDITOR: — Between the hours of 6 P. M. on Tuesday, the 7th instant, and 9 A. M., of Wednesday, the 8th, some one entered my office at "The Pelham" and took the first four volumes of "The Reference Handbook of the Medical Sciences." Other books and articles of greater value they could have more easily taken, and it is curious that only these four volumes were wanted. Any one knowing of these four books being for sale anywhere will confer a favor by notifying

DOUGLAS GRAHAM, 74 Boylston St., Boston.

RECENT DEATHS.

FRANK BOWDITCH CHAPMAN, M.D., M.M.S.S., died in Middleton, June 11, 1897, aged twenty-nine years.

CHARLES EDWARD CLARK, M.D., M.M.S.S., died in Lynn, October 29, 1897, aged fifty-six years.

EBEN THOMPSON, M.D., M.M.S.S., died at Newton Upper Falls, December 7, 1897, aged forty-nine years.

DR. GEORGE C. HOITT, of Manchester, N. H., died December 9, 1897, aged sixty-two years. He graduated from Dartmouth Medical College in the early 80's. He was one of the early members of the board of health and was president of the Sacred Heart Hospital staff.

DR. J. BERRIEN LINDSLEY, secretary of the Tennessee State Board of Health, died in Nashville, December 7, 1897, aged seventy-five years. He was instrumental in establishing the medical department of the University of Nashville, of which faculty he was the first dean, and was for twenty-three years professor of chemistry. His salary was donated to assistants, or went to the support of his journal, the *Nashville Journal of Medicine and Surgery*. In 1855 he was unanimously chosen chancellor of the University of Nashville. In 1870 he took part in forming the "Tennessee College of Pharmacy," of which he had been the professor of materia medica since 1876. In 1880 he was elected to the chair of State preventive medicine in the Medical Department of the University of Tennessee. In 1877 he became a member of the State Board of Health.

BOOKS AND PAMPHLETS RECEIVED.

Heredity. By Clark Bell, Esq., LL.D., New York. Reprint. 1897.

The Treatment of Contusions of the Lids ("Black Eye"). By Charles H. May, M.D., New York. Reprint. 1897.

Transactions of the American Ophthalmological Society, Thirty-third Annual Meeting, Washington, D. C. 1897.

Cerebral Arterial Thrombosis. Chronic Paroxysmal Headache, Commonly Called Migraine, Hemiparesis, or Sick Headache. By Gustavus Eliot, A.M., M.D., New Haven, Conn. Reprints. 1895-1897.

Address in Ophthalmology. Personal Observations on Antiseptics and Anesthetics in Ocular Operations; Perimetry, and Corneal Corneal Activity. By Jos. E. Willets, M.D., Pittsburgh, Pa. Reprint. 1897.

Further Experience with Vaginal Fixation of the Round Ligaments for Backward Displacements of the Uterus. With a tabulated report of fifteen cases. By Hiram N. Vineberg, M.D., New York. Reprint. 1897.

Respiratory Paralysis from Hemorrhage around the Medulla. A Case of Hysteria Simulating Organic Disease of the Brain. Nervous Disorders Simulating Peritonitis. By S. D. Hopkins, M.D., Denver, Col. Reprints. 1897.

Manual of Gynecology. By Henry T. Byford, M.D., Professor of Gynecology and Clinical Gynecology in the College of Physicians and Surgeons of Chicago; Professor of Clinical Gynecology in the Woman's Medical School of Northwestern University. Second edition, containing 341 illustrations, many of which are original. Philadelphia: P. Blakiston, Son & Co. 1897.

Original Articles.

CHLOROFORM AND ETHER.

A CRITICISM OF DR. LEONARD HILL'S ADDRESS, WITH SOME REMARKS ON SYNCOPES UNDER ANESTHETICS.

BY D. E. KEEFE, M.D., SPRINGFIELD, MASS.

AFTER the extensive and ought-to-be conclusive study and experiments of the second Hyderabad Commission, the Glasgow Committee, Dr. H. C. Wood's able paper read at the Tenth International Medical Congress, the painstaking work of Gaskell and Shore, and the honest and scientific work of Dr. H. A. Hare, Dr. Thornton, Dr. Dudley Buxton, and many others whom I might mention, one would suppose that the relative position of chloroform and ether would have been settled for all time. But, lo! like Banquo's ghost, the subject will not down.

I notice in your issue of August 26, 1897, an editorial, based largely upon an address delivered by Dr. Leonard Hill, Lecturer on Physiology at the London Hospital, before the London Society of Anesthetists, on "The Causation of Chloroform Syncope." Added to this editorial was a synopsis of his conclusions. While he said many good things, and while I consider his address a valuable contribution to the literature of the subject, many of his statements seem to me inexact, exaggerated or entirely erroneous. I desire to occupy a portion of your valuable space in drawing attention to some of them, also to give expression to some of my own ideas on this subject.

Be it understood at the outset that I have no intention to impugn either his ability, honesty or entire good faith in this matter. I shall here reproduce enough of the sentences or paragraphs that I desire to criticize, so that all readers can the better judge as to the justice of my strictures.

Dr. Hill *very modestly*, as it seems to me, not only endeavors to controvert the conclusions of the Hyderabad Commission but its ability to read aright the records of its own work as well. Referring to the belief that death under chloroform takes place from primary respiratory paralysis, or, in other words, that respiration ceases before the heart, he says: "This doctrine has been industriously spread abroad, and instilled into the minds of the whole medical world." "This doctrine long received by many with credence." First of all, I deny most emphatically that any such doctrine has ever been received by or instilled into the medical world, if by the world we are to understand a majority of physicians. Indeed, speaking from my personal knowledge, and after consulting the literature of the subject, I am convinced that *precisely the contrary* obtains. True, the findings of the Hyderabad Commission encouraged this belief, but these findings were, almost immediately, neutralized by the contrary findings of the Glasgow Committee, the experiments of Wood and Hare and many others. So the subject still remained *sub judice*. With reference to his statement of twelve deaths in one London hospital in a single year being ("This is no exceptional case"), *no exceptional case*, I have to say, that during the summer of 1890, while *en route* to attend the Tenth International Medical Congress, it was my good fortune, and pleasure, also, to spend several weeks in London, during which time I was a daily attendant at the clinics in the different hospitals. At the very hospital with which

Dr. Hill is connected I witnessed a serious interference with the progress of an operation by reason of chloroform syncope, due to the administrator having been more interested in the operation than his administration. As a result of keeping the anesthetic too long applied, the patient was very nearly beyond the need of operation. However, he was resuscitated, and the operation happily completed. Notwithstanding this, I have too much confidence in the ability and discretion of the surgeons and anesthetists of London to easily believe that twelve deaths in a single year is anything but an exceptional case, and I challenge proof of this statement.

With regard to the manner of death under chloroform, the writer believes that death may take place either by primary cardiac syncope or respiratory arrest. In deaths early in the anesthesia, or before complete sopor, respiratory arrest is a frequent cause, as cardiac syncope is in the later period, or after long operations; but usually the suspension of both cardiac and respiratory action occurs synchronously. True, there may be automatic movements of the chest after the heart has ceased to beat, but there is no true respiration, as can be ascertained by placing the ear to the chest. I am convinced that death under ordinary anesthesia is in all cases due, not to the direct action of any anesthetic either on circulatory or respiratory organs themselves, not to any action on the muscular fibres, howsoever powerful it may be, but to their action on the local nerve endings, and principally upon the centres in the medulla presiding over these organs. Moreover, I believe, that excluding the effects of fear, alcoholic and other degenerative changes, a healthy person should never die during the early or pre-soporose stage of anesthesia. In the very few experiments I have performed on animals—old horses, dogs and cats—I have never been able to cause death until the post-soporose period. This is not in accordance with the findings of MacWilliam and Hill, but it corresponds with the experiments of the Hyderabad Commission. I think, therefore, that too many words and too much time have been spent on this subject—ever so important though it be. I say this advisedly, for when such an emergency arises there are few men indeed who retain sufficient calmness and self-control to be certain as to whether the heart beats or not, or if there is absolutely any air entering the lungs, much less tell which was the first to stop, circulation or respiration.

To return to Dr. Hill, he says: "Gaskell and Shore and Hare and Thornton found the injection of chloroform into the jugular vein produced cardiac, followed, not preceded, by respiratory failure, a fact which the Hyderabad Commission failed to find, owing to the fact that pure instead of diluted chloroform was used, that the vein was tied above the point of injection, and that a needle was used as an indicator of cardiac action." The reasons here given are entirely insufficient, and to the unsophisticated would prove that the Hyderabad Commission, instead of being "unphysiological," used a very conclusive experiment, whereas his reasoning is fallacious. If, in the hands of Gaskell and Shore and Hare and Thornton, the injection of diluted chloroform into the jugulars caused primary cardiac paralysis, why should not the same agent in full strength in the hands of the Hyderabad Commission accomplish the same result, especially with the jugulars tied above the point of injection, thus excluding any possibility

of uncertainty.¹ "The heart is rapidly paralyzed by chloroform and the respiratory centre is paralyzed, while the vaso-motor centre is excited to increased action." This sentence, to my mind, is self-contradictory, for while I doubt not that at any time, and especially after long-continued inhalation, the heart and respiratory centre may be paralyzed, I cannot understand how, at the same time, the vaso-motor centre is excited to increased action. Moreover, all who have essayed to locate these centres have located them so near together in the medulla that anything circulating in the blood in sufficient quantity to paralyze the one would, of necessity, act in like manner upon the other. Most assuredly, it would not have a diametrically opposite effect.

We now come to the consideration of his conclusions, ten in number. In number one, he says: "The respiratory centre fails to act not only because it is damaged by the drug but because of the anemia of the spinal bulb, produced by the fall of arterial tension." This is proved by the fact that the action of the respiratory centre can be renewed by raising the arterial tension." One sentence of this paragraph contradicts the other. For, if the centre were damaged by the drug, when more blood was sent by raising the tension, this blood would contain relatively as large, or even larger, quantity of the drug, and hence the damage would be increased, if the centre were not utterly destroyed. So we would lose more by the added quantity of the drug than we would gain by the relief of the anemic condition. The very fact that increased tension will relieve this condition proves, not that the centre is damaged, but directly the contrary. For, were the centre damaged, all our efforts would, I fear, prove futile. The condition, as I pointed out in a paper read at the Tenth International Medical Congress at Berlin (see proceedings), is purely functional, being due neither to anemia nor damage by the drug, but to congestion, and is usually amenable to proper treatment. Again: "The depth of the anesthesia depends, as does the paralysis of the respiratory centre, on the primary fall of the arterial tension." That there is a gradual fall of arterial tension as the anesthesia is prolonged is conceded by all, but that the anesthesia depends as to depth or completeness on this, I would not for a moment admit. The statement is contrary to the experience and posi-

tive knowledge of every one used to the administration of these agents. Moreover, has he not described one, the late kind of syncope of which he says: "The arterial pressure falls lower and lower?" Would he have us believe that the anesthesia is of greater depth during primary struggling than during late sopor? Furthermore, how is it that ether, which most regard as stimulant to vaso-motor centres, produces profound anesthesia? If the anesthesia and paralysis of the respiratory centre maintain a *pari-passu* relation to lowered arterial tension, is this not a good argument in favor of primary respiratory paralysis? Conceding that under these, or, indeed, under any, circumstances, the respiratory centre may be paralyzed, it requires not such a great stretch of the imagination to think that, under some circumstances, this may occur primarily. But the primary respiratory syncope is due, as I insisted in my paper "Studies in Anesthetics and Anesthetics," published in the *Boston Medical and Surgical Journal*, November 28, 1895, to congestion, not anemia, of the motor centres, still that there was a progressive fall in the arterial tension, and that finally the anemia might be of such a degree as to bring us to another danger-point. "Chloroform also produces paralytic dilatation of the heart. It acts directly, like amyl nitrite, on the musculature of the whole vascular system." I contend that the action of chloroform is not directly on the heart muscle, but almost entirely on the nerve endings and on the cerebro-spinal centres presiding over motion and sensation.² Were chloroform so inimical to muscular tissues *per se*, the bronchial tubes and all the respiratory muscular tissues, which receive it most directly and in its greatest strength, and hence sustain the brunt of the blow, so to speak, would be paralyzed before the heart, at least in a greater ratio than now obtains. Truly this would be yet another argument in favor of primary respiratory rather than cardiac paralysis. The lowered arterial tension, which he likens to the action of amyl nitrite, is not without its favorable side. By it the heart gains fully as much by the increased capacity of the vascular apparatus, and by the ease with which the blood is propelled, as it loses by its own want of tone. The very idea of chloroform passing through the lungs without doing any damage — no, not even irritating them, but going thence to another muscle (the heart) and paralyzing that organ — is both unreasonable and unscientific.

"There are two kinds of chloroform syncope: (a) During primary anesthetization. The patient struggles, holds his breath, raises the intra-thoracic pressure, congests his venous system, lowers his arterial tension, and finally takes deep inspirations and surcharges his lungs with chloroform. In the first stage the left heart becomes impoverished; in the second stage it is suddenly filled with blood. This is drawn from the lungs and is full of chloroform; the chloroform passes into the coronary arteries and the heart is thrown into paralytic dilatation. Respiration and pulse either cease simultaneously, or the pulse before respiration." Part of this picture is true, but the struggle, holding the breath and congesting the venous system are incompatible with "lowers the arterial tension," for it is the struggling and holding the breath and doing away with respiratory pump action that causes the venous congestion and also the heightened

¹ Dr. Hill's claim that, because in the experiment of the Hyderabad Commission, the jugular was tied before injecting the alcohol, it could not go to the heart but remained in the vessel, would be conclusive and unanswerable if the experiment was performed in the laboratory, with glass or any other rigid or incompressible tubes. But with a collapsible elastic tube, having a suction force at the open end, the walls may be made to approach each other, and the tube may be emptied of its contents. We have, in the jugular, this very condition. The auricle exerts a suction force by reason of the pump action of the respiratory movements. More than this, we have a tube with longitudinal and circular muscular fibres in its walls capable of contracting. In the chloroform we have an irritant to stimulate these fibres, not only to ordinary, but to extraordinary action. All these considerations make the experiment not so unphysiological as he would have us believe. On the contrary, they make it reasonably certain that the chloroform did not remain in the vessel, but all, or part, of it reached the heart. Had it not, would not the experimenters most assuredly have noticed the complete absence of symptoms? Furthermore, if the heart were actually paralyzed by this jugular experiment, as Gaskill and Shore found, it would prove nothing when applied to ordinary inhalation.

I suppose no one will dispute that chloroform, if concentrated enough and long enough applied directly to the heart, will paralyze the nerve endings, the cardiac ganglia and, indeed, even the muscle itself. In this experiment the heart would be the first structure with which the chloroform comes in contact. This is a condition not possible in ordinary anesthesia, for here we are dealing with the vapor of chloroform and the lungs are the first organs with which it comes in contact; hence, if it proved anything, it proved not that it paralyzed the heart, but that it paralyzed the first organ to receive its impact, and in ordinary inhalation the lungs are the first organs to receive it. Therefore, it would be a proof of primary respiratory rather than cardiac paralysis.

² The experiments of Waller, as given before the British Medical Association at Montreal, I think, support this view.

arterial tension. So, too, the lowered arterial tension is incompatible with obstructed respiration and venous congestion, for these very conditions cause increase in arterial tension. Furthermore, I cannot see how ("finally takes deep inspirations and surcharges the lungs with chloroform") the lungs are so surcharged with chloroform. If, as he is common with all other writers advise, the anesthetic be withdrawn during the period of struggling—indeed, though it were not withdrawn, so long as the relative dilution of the chloroform vapor was maintained, as we have a right to assume—how could the lungs be surcharged, for as soon as sopor supervened the inhaler would be again withdrawn?

The writer thinks he has given an explanation of this respiratory syncope more in consonance with the existing physiological conditions than any he has seen elsewhere (see paper in *Boston Medical and Surgical Journal* before referred to). It is as follows: "Believing, as I do, that the heart is beating at its maximum as to force and frequency when the anesthetic is applied, the blood is being pumped into the brain with great force and in large volume, the irritating action of the drug upon the respiratory mucous membrane produces a state of spasm of all the muscles of respiration, thus forming an obstruction to the return current from the brain. The congestion so induced may be of such a degree that the resulting pressure on the cardiac and respiratory centres in the medulla may prove inhibitory and death ensue, either from cardiac syncope or respiratory arrest; most likely the latter." Dr. Hill's statement, that "the chloroform passes into the coronary arteries and the heart is thrown into paralytic dilatation," seems to me entirely untenable. Why has it not acted on the arteries and the veins of the lungs? As I before stated, it acts, not by nutritional changes alone—nor, indeed, to any great extent—but by paralyzing the power of the nervous system to originate and transmit stimuli.

In describing the second form of chloroform syncope, he says: "During prolonged anesthetization, this arises from gradually giving chloroform to too great an extent. The arterial pressure falls lower and lower, and, secondly, the respiration ceases, because of the anemia of the spinal bulb." Here he gives us a sample of primary respiratory paralysis, which, from this paragraph, one would take to be the usual manner of death in prolonged inhalations; the very teaching which he has previously declared to be "one of the most pernicious and dangerous doctrines ever put before the medical profession." "This doctrine, received by many with credence, is that chloroform kills by paralyzing the respiratory centre." Here we have, then, a fine example of that jewel, consistency. He makes mention of "giving chloroform to too great an extent." I cannot understand what he wishes to imply, whether he means too long administration or too large quantity of the drug. I always supposed that one gave only just enough to keep the patient under, and, of course, that is absolutely necessary. From the statement that "artificial respiration and horizontal position, if applied in time, will always resuscitate a patient from the second form of syncope," I must respectfully dissent, as it is much too strong; moreover, the contrary has been repeatedly proven.

Dr. Hill's recommendations for the treatment of the two kinds of syncope which he describes are in the main sound; but I am surprised that in the first kind

(a), where he says the heart is thrown into paralytic dilatation that he does not mention the hypodermic use of digitalis in any of its forms, strychnia, or electricity. Also in the kind (b) where there is respiratory failure with anemia that he fails to mention that great respiratory stimulant, strychnia.

I think a careful review of this paper would enable us to draw the following conclusions:

(1) Statistics are at present of little or no value in deciding as to the relative danger of chloroform and ether, because, as I have shown in a previous paper, the deaths under both bear a lower ratio to the inhalations than the sudden deaths in those who had not taken an anesthetic bear to the population.

(2) Ether is a safer anesthetic in proportion as it is weaker, bearing a relation to chloroform of about one to five. The danger of chloroform is not so much inherent to it *per se* as to its relative greater strength and the greater care and experience required in its administration. I would trust almost any physician to give ether, but not one in twenty to administer chloroform. Just as any child can handle a toy engine, but not every man can handle a steam locomotive.

(3) The difficulties with both chloroform and ether in the pre-soporose stage are, in nearly all cases, due to respiratory spasm, and the consequent heightened arterial tension and venous congestion. This is very likely to be unduly prominent in the brain on account of recumbency, and the few muscular fibres in its vessels in comparison to the general circulatory system. For this reason it is neither so well able to resist the onset by contracting its arteries nor to empty itself.

(4) In the post-stertorous stage, after long application, the death is most likely to be caused by anemia and cardiac paralysis.

(5) The best medicine for the first kind of interference is amyl nitrite, belladonna and strychnia; and for the second, digitalis and strychnia, supplemented by electricity and all the other movements recommended by Dr. Hill.

(6) Were I asked for the greatest advantage ether has over chloroform I would say: The anesthesia of ether is loud and lifelike; hence any accident or interference is noticeable on the instant; whereas chloroform produces so quiet a sleep that the patient seems on the borderland of the grave, and there is not so distinct a warning of accident until too late; consequently it requires a degree of vigilance and attention that few possess. Moreover, the administrator, if conscientious, feels that he assumes a greater responsibility than the operator.

(7) Chloroform is a more satisfactory anesthetic for short operations, where the sopor need not be renewed or continued; for obstetrics, where the anesthesia need not be complete; and for patients with lung or kidney disease, and children.

(8) Ether is, I think, pleasanter and safer (for the vast majority of physicians) to continue the anesthetic state after having been induced by chloroform.

(9) I do not believe there is any well-marked difference in the manner of death under ether or chloroform; the stage of the anesthesia has more to do with it than the agent.

A LIFE OF PASTEUR.—It is announced that a biography of Pasteur is in preparation, its author being Pasteur's son-in-law, M. Vallery Radot.

OCULAR HEADACHES.¹

BY ALLEN GREENWOOD, M.D., WALTHAM, MASS.

It is hardly necessary at the present day for me to suggest to you what an important part errors in refraction and muscular insufficiencies play in the etiology of headaches.

During the past few years much has been written on this subject and many valuable statistics have been compiled.

It is undoubtedly true that for a time, as in all new lines of medical progress, the pendulum swung much too far, until it was claimed that in the correction of refractive and muscular errors lay the secret of the successful treatment of almost all the functional nervous diseases. This condition might be compared to the wonderful results promised at one time for the operation of oöphorectomy, except that the slight inconvenience of wearing glasses can hardly be compared with the seriousness of an abdominal section.

At the present day, however, the pendulum has practically settled, and the therapeutic results to be obtained by the wearing of lenses are fairly well understood. Many physicians make a practice of having their patient's eyes tested before beginning any treatment for persistent headache. Physicians often do not realize what an important part these errors play in cases of headache where, to the ordinary rough tests, the eye-sight seems perfect. It should be constantly borne in mind that the errors most productive of eye-strain are the ones that affect the acuity of vision the least.

How often every oculist hears a story like the following: "My family physician has been unable to cure my headaches and has sent me to have my eyes tested to see if there is any cause for my trouble there, but I know it cannot be so for my eye-sight is perfect both for distance and for reading." A careful examination, however, may reveal a slight amount of astigmatism, and when the sceptical patient begins to wear the correcting lenses the headaches disappear to his surprise and gratification.

A history of occasional headaches coming on in the afternoon after reading or sewing, and gradually coming more and more frequently, until they are almost constant and appear with the opening of the eyes in the morning, should make one strongly suspect refractive error as the cause. This cause should always be suspected when a visit to the theatre, picture gallery, concert hall, or a day's shopping ends with a severe headache. In fact, it has been my experience that no severer test can be put on slightly astigmatic eyes than an evening spent at a theatre. Many patients come complaining of what they call their "theatre or Boston headaches," and in some cases this is the only time when they are afflicted and many patients often experience the greatest benefit from their lenses at the theatre.

The occasional attacks of so-called sick-headache, to which some school-children are subject, are often found to be caused by refractive defects, the careful correction of which prevents future trouble. In these cases the child forces the eyes to do the work they are unequal to, until the ciliary muscles and nerves become exhausted and painful. The pain is usually confined to one eye or the region around it and is often severe enough to cause reflex vomiting.

A night's sleep will, by the complete rest afforded the muscles and nerves, cure the present attack, and the next day the child can return to school with eyes capable of keeping up the unnatural strain for a longer or shorter period according to the vigor of the child and the amount of the defect.

In regard to the site of ocular headaches, I have found that the frontal region is most often affected. Next in order of frequency comes temporal, and then occipital, headaches.

In order to present the subject to you, I have very carefully reviewed and tabulated 900 cases of refractive and muscular errors. These are not selected cases, but represent the cases of this kind coming under my care during the past few years. My object in the tabulation is to show what proportion of the cases had headache as the most important symptom and the measure of relief obtained in such cases by the use of lenses.

I have not tabulated the eyes separately, as is often done, but have classified cases where the eyes were very different, according to the error existing in the eye that seemed most at fault.

For instance: in a case where one eye is myopic and amblyopic and the other is slightly astigmatic, but with good acuity of vision, it is evident that the eye which does all the work is the one at fault in causing the headaches, and the case is classified accordingly.

In looking at the table, the number of cases of muscular insufficiency may seem small, but under that head I have put only such cases as had some well-marked muscular trouble, accompanied by a slight or no refractive error.

Very many of the refractive cases were complicated with slight exophoria, esophoria, or hyperphoria, and at one time I was in the habit of ordering prisms combined with the lenses correcting the refractive error. Now, however, I very rarely do so, for, by experience, I have found that the correction of the refractive error will do away with the muscular trouble in the majority of cases, and the use of prisms is often unnecessary, and may do harm by more firmly establishing the lack of muscular equilibrium. The exception to this is in cases of hyperphoria, where a correcting prism is more often necessary.

In studying the table, you will notice that, out of the 900 cases, 480 were found having headache as an important symptom; and in many cases it was the only one, no symptom referable directly to the eyes being present.

In the other column is included those cases complaining of poor vision—blurring after use, and other symptoms pointing directly to the eyes.

Of the cases accompanied by headache and treated by the use of lenses to correct the refractive error, or in some cases by rest and tonics, 239 are classified as entirely relieved, 134 as partly relieved, 43 as unrelieved and 64 as unknown.

It is undoubtedly true that many of those unrelieved could have been had they permitted the more accurate test under the use of atropine; and many of the unknown were probably so fully relieved as to consider it unnecessary to return as requested. Taking these things into consideration, I think these figures are as accurate as is possible in this group of cases.

Every oculist recognizes a class of hysterical patients whose headaches are relieved every time a different

¹ Read before the Waltham Medical Club, May 6, 1897.

oculist changes the glasses, but they soon relapse after the suggestive effect has worn off.

One fact is well brought out by the table, namely, that, except in the case of myopia, the less the refractive error the greater is the liability of its causing headache, and thus we find confirmed the observation that often the cases presenting the most violent headaches have apparently perfect sight and no distinctly ocular symptoms.

Another observation which I have not brought out by the tabulation, but which during my review of the cases was forcibly impressed upon me, is the fact that in cases of astigmatism where the axis was contrary to the rule very great trouble was experienced by the patient, and equally great relief derived from the correcting lenses.

I should state here that in grading the amount of

ILLUSTRATIVE CASES.

CASE I. Hypermetropic astigmatism against the rule. Miss E. A., age twenty-one. August 9, 1892.

For several years has had a good deal of headache. Lately, she has had this constantly, and has been advised to stop teaching school. Under a mydriatic I found astigmatism of $+25$ D.; axis of cylinder, 180° . She has worn lenses ever since, with perfect relief.

CASE II. Myopic astigmatism. Miss G. V. W., age twenty-nine. August 28, 1892.

Always troubled, more or less, with headache, but now has severe occipital headache, extending down into the back between the shoulder-blades.

Under mydriatic examination showed

$$\begin{aligned} \text{O. D. V.} &= \frac{20}{40} \text{ C} - 1 \text{ cyl. axis } 180^\circ = \frac{20}{20} \\ \text{O. S. V.} &= \frac{20}{40} \text{ C} - .75 \text{ cyl. axis } 180^\circ = \frac{20}{20} \end{aligned}$$

Error.	Grade.	Without Headache	With Headache	Entirely Relieved	Partially Relieved	Unrelieved	Unknown	Totals
Hypermetropia	High	5	1	1	6
	Medium	34	19	9	7	2	1	53
	Low	26	48	26	14	..	8	74
Hypermetropic Astigmatism	High	1	1	1	2
	Medium	16	14	8	4	1	1	30
	Low	40	125	58	33	15	19	165
Compound Hypermetropic Astigmatism	High	1	5	1	2	..	2	6
	Medium	17	30	17	8	1	4	47
	Low	10	47	21	14	4	8	57

Muscular Insufficiencies		14	20	2	11	2	5	34
Presbyopia		125	5	1	2	2	..	130
Totals,		420	480	239	134	43	64	900

error I have included under low degrees all up to one dioptré, under medium all from one dioptré up to five, and under high all above five.

It will be noticed that more than half the cases having headaches came under the simple forms of astigmatism, and of these the greater number were hypermetropic.

If all the cases of myopic astigmatism had been tested under atropine, many of them would probably have been found to belong to the hypermetropic list.

When one is in doubt whether to order the *minus* or *plus* cylinder, I find it a good rule to follow, that, if there is esophoria, order the *plus* cylinder, and exophoria order the *minus* cylinder.

Under the heading of Presbyopia, I have included only the simple cases, the cases accompanied by marked refractive error being classified under one of the headings above, according to the refractive condition.

The cases were worked out by means of skiascopy followed by the use of the trial case. In many cases a mydriatic was used.

Wearing the above correcting lenses entirely relieved all the pain in the head and back.

CASE III. Exophoria. Miss L. B., age twenty. April 15, 1894.

She was so much troubled with headache that she could scarcely keep on with her work. Examination showed

$$\begin{aligned} \text{V. O. U.} &= \frac{20}{30} \text{ Hm. } + .75 \text{ sph. } = \frac{20}{20} \\ \text{Exophoria of } 18^\circ &\text{ for distance} \\ \text{Abduction} &= 15^\circ \\ \text{Adduction} &= 3^\circ \end{aligned}$$

Under cocaine, the left external rectus was cut, and lenses of $+75$ sph. were ordered for constant use. After several weeks, examination showed an exophoria of one degree for distance. The headaches were greatly relieved.

CASE IV. Astigmatism against the rule. Miss N. E. S., age twenty-nine. October 29, 1894.

Has been troubled with headaches ever since she can remember, and was obliged to leave school long before she had finished the course she had begun. During the past four years she has been confined to the house with

nearly constant headaches, and a great deal of the time obliged to lie quiet in a dark room. The frequent vomiting caused by the pain has resulted in a chronic dyspepsia, so that she has to be very careful of her diet. For years she has been unable to do any reading or other fine work, and has been under medical care since she has been confined to the house.

Her condition was such that she could not come to my office, so that the examination was made at her house. Examination showed—

O. D. V. = $\frac{20}{30}$ \bigcirc — .25 cyl. axis 90° = $\frac{20}{30}$
 O. S. V. = $\frac{20}{40}$ \bigcirc — .75 cyl. axis 90° = $\frac{20}{30}$

Lenses afforded her immediate relief, and in a week's time she was able to go to church, the stomach trouble had ceased, and she could read and sew as much as she wished. Since then she has been perfectly well and entirely free from headaches.

CASE V. Myopic astigmatism. Mrs. N. S. A., age forty-five. December 17, 1894.

Has always had headache, especially after reading, and has what she calls Boston headaches when she goes shopping. Examination showed—

O. D. V. = $\frac{20}{30}$ \bigcirc — .75 cyl. axis 112° = $\frac{20}{30}$
 O. S. V. = $\frac{20}{100}$ \bigcirc — .4 cyl. axis 12° \bigcirc + .50 sph. = $\frac{20}{30}$

Wearing lenses prevents her having headaches. For reading she wears a + glass added to the above correction.

CASE VI. Astigmatism against the rule. Mrs. F. S., age thirty-eight. February 15, 1897.

She has had headaches all her life; and five years ago she had nervous prostration. The past few months she has had severe headache and has become cross and irritable. About three months ago she had an operation for an old perineal tear, with hope of relieving the nervous symptoms. She is afraid of having nervous prostration again. Examination showed—

O. D. V. = $\frac{20}{30}$ \bigcirc + .50 cyl. axis 180° = $\frac{20}{30}$
 O. S. V. = $\frac{20}{30}$ \bigcirc + .37 cyl. axis 180° = $\frac{20}{30}$

Wearing glasses has relieved all her symptoms.

ACQUIRED IDIOSYNCRASY FOR QUININE, AS SHOWN BY PURPURA AND BLEEDING OF THE GUMS.¹

BY DOUGLASS W. MONTGOMERY, M.D., SAN FRANCISCO,
Professor of Diseases of the Skin, Medical Department of the University of California.

MANIFEST effects of quinine on the skin are rare when one considers how frequently this drug is taken; but when they do occur, the clinical picture is so dissimilar in different cases as to make it almost incredible that they are to be attributed to one cause. In one man quinine will give rise to violent itching, in another to urticaria, in another to a simple erythema, or a scarlatiniform erythema, or even a rash simulating an erythema multiforme. An erysipeloid, a complete exfoliative, or even a gangrenous dermatitis have been ascribed to quinine. Furthermore, quinine can cause an erythematopurpuric rash, an eczema, or even a bullous eruption.

Besides these disagreeable inflammatory manifestations, quinine may produce more or less extensive extravasations of blood into the skin, and sometimes oozing of blood from the mucous membranes, constituting

a purpura, of which I believe the following case to be an example:

On August 8, 1895, a fairly strong-looking man, twenty-nine years of age, was sent to me by a dentist to ascertain if there would be any risk from hemorrhage in having a tooth extracted. The patient told me that about two years before, the second right lower bicuspid had been pulled out, leaving however, some fragments of roots, which were extracted about two months before he came to me. Two days later he had been awakened at night by bleeding, as he supposed, from the place where the roots had been extracted, and the oozing had continued for about forty-eight hours. At the same time there was subconjunctival hemorrhage of the right eye, and a purpura of the skin of the upper eyelid and of the backs of the hands and feet. He did not remember any rheumatic pains during the attack, but he was quite positive that he had never had any similar eruption before, and there was no history of a hemorrhagic diathesis in the family. The blood was normal.

The opinion was given that there would be no risk in extracting a tooth, as the patient was considered to have simply had an unusual attack of purpura rheumatica with bleeding from the mouth, and little or no pains in the joints. It was thought that the hemorrhage was in no way connected with the removal of the fragments of tooth, and that the patient's story of the bleeding being only from the wound in the gums was not an exact observation. The likelihood of the patient having hemophilia seemed to me to be very remote, as he gave no history of any similar bleeding either in himself or in his family. He had the tooth extracted at that time, and it was not followed by any unusual bleeding.

This opinion was given August 8, 1895, and September 12, 1895, I was called again at 9.30 A. M. to see the man. That morning at 5 o'clock he had wakened with pains in the ankles, knees, hips and in the metacarpo-phalangeal joints. The pains were most marked in the hips. On awaking he had vomited quite a large quantity of blood. The gums were oozing blood, the hemorrhage coming from beside the outer side of the upper and lower right and left molars—most freely, however, from the outer side of the lower right molars. There was a pinhead-sized bright red hemorrhage in the conjunctiva of the right eye over the sclerotic of the outer segment of the eyeball, which he said looked exactly the same in the previous attack, and there were several purpuric spots in the integument of the right side of the neck, over the breast bone and elbow tips, and into the skin of the thighs, and over the second joint of the right middle finger. The next day some very small hemorrhages were noticed in the integument of both upper eyelids. As in the previous attack the hemorrhage from the gums lasted about forty-eight hours, and after the second day no new hemorrhages were noticed in the skin, and as for the pains in the joints, they had only been present during the first half day. There was no rise of temperature nor acceleration of pulse-rate, and except for the symptoms enumerated, the patient felt perfectly well during the entire attack.

While questioning him to ascertain the cause of his trouble, it transpired he had taken a five-grain dose of quinine the night before for a cold, "even as you and I"; and then he remembered that just before the previous attack he had taken a ten-grain dose of qui-

¹ Read before the California Academy of Medicine, June 19, 1897.

nine. He said that quinine always had a disagreeable effect on him, causing sickness of the stomach, insomnia, slight headache and buzzing in the ears. Three years before coming to me, however, he had taken the muriate of quinine for a considerable time in twenty-grain doses a day, for what his physician said was malarial poisoning with enlargement of the spleen. The case therefore stood as follows:

A man who had previously taken large doses of quinine with only a few disagreeable sensations, such as ringing in the ears, sickness of the stomach, etc., got, after taking a ten-grain dose of quinine, a purpura, with bleeding in the mouth. He believed this bleeding to come from the side of a tooth from which a number of fragments had recently been removed. Another similar attack occurred after a five-grain dose of quinine, and this time the bleeding in the mouth was certainly not from any wound or ulcer, but was clearly an oozing from the gums beside the molar teeth. The patient was positive no quinine had been taken in the interval between the first and second hemorrhagic attacks.

In a letter written on June 18, 1897, the patient stated that he had had no hemorrhagic attacks since September, 1895, and also that he had carefully abstained from taking quinine.

Of course, one is aware when studying an uncomplicated case of purpura like the above, that one has to do with a single symptom, minute hemorrhages, and that quite a number of diseases and toxic substances occasion such hemorrhages. It was certainly not a case of sporadic scurvy, because the purpura was not particularly in the lower extremities, nor was there any edema or pain, or painful swellings of the legs. The gums were not swollen or fungous or painful; there was no anemia or loss of strength, and the patient had good hygienic surroundings. It was also clearly not the purpura accompanying any of the acute febrile diseases.

It was more difficult to differentiate it from peliosis rheumatica, but even here there were points of difference. The general appearance of the patient was much better than it usually is when peliosis rheumatica is accompanied by copious hemorrhages from the mucous membranes, and in such severe cases there is generally much more extravasation of blood into the skin than was present here. Then, again, the joint symptoms are generally more marked, for in this instance there was only slight pain and no redness or swelling. Furthermore, in peliosis rheumatica there are almost always several successive crops of purpuric spots, and the whole process lasts two or three weeks, while in the case in hand a considerable number of spots appeared on the first day, only a few the second day, and none afterwards. The first attack, that I did not see, seems to have run fully as short a course.

The fact that the patient had previously taken large doses of quinine without experiencing any such serious effects, would seem to invalidate the diagnosis of a quinine purpura; but, as shown by Allen (1) and by Morrow, the susceptibility to quinine poisoning may be acquired. A person who may be able to take quinine now with few or no bad symptoms may afterwards suffer most disagreeable oblique effects on taking a small dose of the drug.

To sum up, the diagnosis of quinine poisoning was made, first, because of the short course of the purpuric attacks, as well as on account of some other minor differences from the usual course of peliosis rheumatica,

which it most closely resembled; and, secondly, because both attacks followed doses of quinine, a drug that is known to give rise to just such hemorrhages.

REFERENCES.

1. Purpura from Quinine. By E. Wigglesworth, M.D. Boston Medical and Surgical Journal, December 20, 1893.
A woman, fifty-two years of age, got a scarlet, non-elevated, irregularly circular patch about the size of a half-dollar on the left forearm one hour after taking a one-grain quinine pill. The spot itched, burned and was tender. She continued taking the pills and more spots appeared and by the seventh day the spots became hemorrhagic.
2. Briquet reported the case (quoted by L. Lewin, *Nebenwirkungen der Arzneimittel*, 1893, p. 465,) of a man suffering from typhoid fever, who took daily a three-grain dose of a quinine salt, and who had hemorrhages in the lumbar and gluteal regions, and a bloody diarrhea.
In another case quoted by Lewin (*vide supra*) a woman got a purpuric eruption and the contents of an artificial blister became bloody after 0.1 gm. of bi-sulphate of quinine every six hours the first day, and 0.15 gm. the second day. At another time after taking a few doses of quinine, purpura again developed. Spitting of blood from bleeding of the gums coincident with purpura hemorrhagica after small doses of quinine has also been observed. (L. Lewin, *vide supra*.)

Clinical Department.

A CASE OF OÖPHORECTOMY DURING LABOR.¹

BY EDWARD REYNOLDS, M.D., BOSTON.

M. D. entered the service of Dr. C. W. Townsend in the Boston Lying-in Hospital in the small hours of the morning of September 4th last, and I saw her with Dr. Townsend at 6 A. M. that morning. The patient had been in labor under the care of a physician outside the hospital for the greater part of two days. Her temperature was normal. Her facial expression was drawn and anxious, looking not unlike the ovarian cachexia (though, in the light of after developments, this may well have been the facies of peritonitis).

On vaginal examination, a large, round, tense mass was immediately apparent. This lay evidently at the bottom of Douglas's fossa, and was of about the size of a seven months' head. The os, dilated to the size of a five-cent piece, could be reached with difficulty above the tumor. By external palpation, the position was found to be left, the head presenting. The patient was etherized and placed in the knee-chest position, and gentle taxis was tried for about ten minutes. This raised the tumor until its greatest diameter was above the brim of the pelvis, but it refused to rise any higher under the amount of force which we thought justifiable. As we were unable to decide whether the tumor was a fibroid or an ovarian growth, and as we were sure that if it was a fibroid it would shortly retract and dispose of itself, we decided to give the patient a short time longer in labor.

We saw her again, with the addition to our consultation of Dr. George Haven, at 10.30 A. M. There had been slight, if any, retraction of the tumor, but as there had been no labor pains until during the last hour of that time, it was thought best to wait a little longer, and nothing further was done until 12 noon, when fairly strong pains having been present for

¹ Read before the Obstetrical Society of Boston, October 19, 1897.

about two hours without progress, the patient was etherized, again placed in the knee-chest position, and gentle taxis performed. There being no more result than before, the patient was turned to her back, and I opened the abdomen by a median incision. On opening the peritoneum a thick, creamy, bloody fluid of grumous odor poured forth, and on enlarging the incision the whole peritoneum was seen to be intensely injected and purplish in color. So soon as the uterus was lifted out of the abdomen, quantities of this foul-smelling fluid escaped, together with large flakes of gray and necrotic-looking lymph. On passing the hand into the pelvis behind the uterus, an oblong tumor was felt, firmly fixed in position by old exudates, which enclosed two encysted cavities full of the same necrotic lymph. The tumor was firmly adherent to the bottom of Douglas's fossa and was itself necrotic. In separating it from its surroundings, its tissue gave way slightly at two spots and a little of the characteristic contents of a dermoid cyst escaped into the cavity of the pelvis. The tumor was tied off with stout catgut and removed. The uterus was allowed to fall back into the abdomen, and Dr. Townsend applied the forceps. These failed to deliver; and a stethoscope failing to detect the fetal heart, Dr. Townsend passed the hand into the uterus, found the cord still, perforated the head, and extracted the child, which was a male, weighing eight and one-quarter pounds, after the removal of its brain. The necrotic lymph flakes were then picked out from among the intestines as carefully as possible and the intestines and mesentery were scrubbed with sponges, beginning at the sigmoid flexure and progressing upwards until about the middle of the small intestine had been reached, when the patient's condition was so extremely bad that I feared a death upon the table, and thought it better to get her at once to bed. Several quarts of warm salt solution were poured over the as yet uncleaned portion of the intestines, hastily stirred about and allowed to flow out from the abdomen, thus removing a considerable additional quantity of the gray-looking lymph. About a quart of the solution, by estimation, was left in the abdomen; a small wick was passed to the bottom of Douglas's fossa at the lower angle of the wound; the remainder of the wound was hastily brought together by three or four sutures; and the patient was put to bed, with the foot of the bed raised. The pulse was then barely distinguishable, in spite of the free use of strychnia and brandy subcutaneously.

Reaction occurred during the second hour. The pulse varied from 150 to 160 during the afternoon. There was no vomiting except slight ether vomiting immediately after the return of consciousness.

The next day, the abdomen being swollen and tympanitic, the patient was given a drachm of Epsom salts in a half-tumblerful of water. This dose was repeated at the end of two hours, but the second dose was vomited. An enema of soap-suds and glycerine given shortly afterwards was followed by the escape of a large amount of flatus, and from this time on for many days the patient passed gas and feces spontaneously at short intervals. There was no more vomiting. The wick was removed at the end of forty-eight hours from the time of operation. The distention was by that time slight, the patient was taking milk and lime-water, and there had been no further vomiting.

On the third day after operation the temperature was 103°. Inspection of a tear in the perineum which

had occurred during the delivery showed it to be covered with a gray pseudo-membraneous deposit. The amount of uterine tenderness could not be judged, but the uterine lochia was suspicious looking. An intra-uterine douche of corrosive sublimate solution was accordingly given, and the surface of the laceration thoroughly dusted with iodoform.

The next day the temperature was but little over 100°. Its course from that time on was steadily downward, and the remainder of the recovery was wholly uneventful, the temperature being normal on the eighth day after delivery. During the first week, the motions averaged from twelve to fifteen in each twenty-four hours, twenty being the highest, no cathartics being given during this period save the two doses of salts already mentioned.

This case is, so far as I know, the first reported case of oöphorectomy during labor, and is of interest if only by reason of its rarity. It is, however, of far greater interest on account of the questions of judgment involved. Only six years ago I reported before this Society two cases in which I had succeeded in raising, by taxis in the knee-chest position, ovarian tumors obstructing delivery, and after advocating the use of gentle but repeated taxis in this position for such cases, stated that in the event of the failure of the taxis, I would advocate the opening of the abdomen in place of the then generally accepted method of vaginal puncture. It is interesting to me to remember the extreme and, I think, unanxious disapprobation with which that proposal was received, the members of the Society all stating that they would take any of the risks which might follow vaginal puncture in preference to the adoption of so radical a measure as an abdominal incision. I hardly think that such a position could be taken to-night.

In the light of after-events it is probable that both the delay and the use of taxis were unfortunate in this case, yet in view of my personal experience of two ovarian tumors and seven fibroids prolapsed in advance of the head, all treated successfully by expectant methods and the taxis, without the loss of a mother or child, I must still hold that in such cases the abdominal operation should always be preceded by full and repeated trials of the taxis. It had been my plan to have removed the child by the Cesarean section before performing the oöphorectomy, but the fact that the woman had been through a prolonged labor in dirty surroundings before entering the hospital, and the consequent possibility that the uterus was already infected, together with the presence of an active peritonitis, which was first discovered during the operation, made me feel that opening the uterus would probably sacrifice the mother's last chance; and as there was no reason to suspect that the intrapelvic delivery would be difficult, I decided upon this method, with the hearty assent of both my colleagues. This decision, as events proved, undoubtedly sacrificed the child, but I think that it probably saved the mother. The failure of the forceps to extract was due to the existence of a tight constriction ring around the neck, and this is perhaps the first instance in which such a uterus has been seen by direct inspection. Its appearance was most curious, the head of the child being contained in a spherical lower portion of the uterus, while its body was drawn into such extreme flexion by the contracting uterine muscles that its backbone lay almost transversely across the abdomen,

the uterus having thus an extraordinarily hammer-headed or T-shaped outline. The breech occupied one end of the hammer-head and the shoulders the other, while the head in the lower uterine segment, or handle of the hammer, seemed to be almost midway between the two.

In conclusion, and for the sake of exciting discussion, I would state that my personal position on the treatment of ovarian tumors obstructing labor is now —

First, that the first expedient tried should be gentle taxis with the patient in the knee-chest position, and, if necessary, etherized.

Second, if the taxis is unsuccessful, it should be repeated after the lapse of one or two hours; but if this attempt fails, the abdomen should be opened, and under ordinary circumstances the uterus should be incised and the fetus removed. The tumor should then be inspected, and unless its removal promises exceptional difficulty, it should be freed, tied off and removed.

Third, in the event of unusually firm adhesions in the pelvic cavity, it would be better to defer the removal of the ovarian tumor to a subsequent operation at a time when the pelvic veins and arteries are not of the enormous size they attain at the conclusion of pregnancy.

Fourth, when there is a fair probability that the patient has already been infected with sepsis per vaginam, it would be better in most cases to lift the uterus forward without opening it, remove the tumor, and then let the child take its chances with an instrumental intra-pelvic delivery rather than risk putting the mother's peritoneum into communication with an infected uterine mucosa.

ANTITOXIN AS A PROPHYLACTIC.

BY EDWARD L. TWOMBLY, M.D., BOSTON.

THE Gwynne Temporary Home for Children, on Worcester Street, is divided into three separate departments: (1) for babies under one year, received for adoption; (2) for children between two and three years old who are taken in temporarily, when by reason of sickness and poverty the parents, or, more probably, the mother, cannot care for them; (3) the kindergarten for children from four to fourteen years, also taken temporarily for one or two months under the same necessities.

A family of four children was admitted on June 3d, and five days afterwards three of them broke out with measles and gave them to the other children in the home. Meanwhile the eldest, a girl of thirteen, who had had the measles, showed a sore throat, which the culture-test proved to be diphtheria. Her sister (nine years) also developed diphtheria on June 28th, and a boy of five years, who was in the bed next to her with measles, showed the positive signs on July 1st. They were promptly isolated and sent to the hospital.

A second focus of infection came in the shape of a boy of ten years, who brought the disease on July 2d. Two more children were infected through him, diphtheria appearing in them on July 8th and 9th.

The next day, eleven injections of antitoxin were given to the school-room children who had been exposed, and we hoped that there would be no further trouble. But a girl of thirteen in the school-room where there had been no cases up to July 1st had been

sent into the two-year-old nursery to assist the regular nurse with her cases of measles, and she came down with diphtheria on July 9th, and communicated the disease to four others, it appearing on the 13th and 16th.

All the remaining children and the nurse, ten in all, were then injected with the antitoxin, July 16th, and we had no more diphtheria.

Judging by the facts in these cases, it is but fair to conclude that antitoxin was the agent which gave these twenty-one children and nurse who had been exposed, complete immunity from the disease.

The injections were given to children of all ages, as may be seen by the accompanying table, and the disturbance caused by the antitoxin was practically nothing.

¹ Enlargement of cervical glands in both cases.

² Enlargement of axillary glands; general urticaria ten days, afterwards for two days.

Last year I gave fourteen injections for the same purpose, with success; but two-thirds of the cases had some form of either local or general urticaria. All recovered from it in a few days without special treatment.

I attribute my better results this year (1) to the good serum, which has been brought to its present state of perfection and freely given to the profession by Dr. Harold C. Ernst, of the Bacteriological Laboratory of the Harvard Medical School; (2) to the smallness of the dose (two to five cubic centimetres instead of eight to ten cubic centimetres, which were used last year) as the serum is made now of greater strength; (3) the care in boiling the needle after rinsing with water after each injection; and (4) the place chosen for inserting the needle, which was in the loose folds of skin in the posterior right axillary line, over the lower ribs and above the line of the bend of the elbow at the side. The antitoxin seemed to be absorbed more readily than if it had been injected on the outside of the thigh, as was done in the cases of last year, when so much urticarial disturbance was noticed.

In conclusion, I would call attention to the small doses (one-third to one-half the regular dose) that seem sufficient to immunize our little patients; the greater susceptibility to diphtherial poison after or during measles; and the absence of any dangerous effect where proper serum is properly given.

At a recent meeting of the Section in Ophthalmology of the College of Physicians of Philadelphia, Dr. de Schweinitz stated that Dr. Barrett, of Melbourne, had described a form of amblyopia in horses which was attributed to their eating some plant, probably the Australian tobacco plant. By the courtesy of Dr. Barrett Dr. de Schweinitz was enabled to exhibit two slides which Dr. Barrett had prepared from the optic nerves of a horse which had become blind. The sections showed fibrosis with degeneration of the nerve fibres.

Medical Progress.

REPORT ON DISEASES IN CHILDREN.

BY T. M. ROTCH, M.D., AND A. H. WENTWORTH, M.D.

THE BACTERIOLOGY OF PERTUSSIS.¹

KOPLIK refers to the contradictory results obtained by various observers during the last ten years from the examination of the sputum of patients with pertussis. His own observations are based upon a careful bacteriological examination of the sputum from 16 cases. In addition to the ordinary culture media, he made use of hydrocele fluid, and found the latter to be superior to the former, inasmuch as it enabled him to isolate a bacillus *x*, and to obtain pure cultures of the same in the presence of other organisms. In 13 of the 16 cases this bacillus was present in the sputum, as shown by cover-glass preparations and cultures, either alone, or associated with various diplococci, diplococcus lanceolatus and streptococci.

In uncomplicated cases the bacillus was easy to isolate. In cases complicated with bronchitis and pneumonia the other organisms grew so profusely as to mask the growth of the bacillus. The author ascribes the failure of many observers to find the bacillus to this cause. The organism is easily found in cover-glass preparations from the sputum, stained with Löffler's methylene-blue, but is difficult to isolate from other organisms on ordinary culture media.

Cultures were obtained from clumps of sputum on hydrocele fluid, or hydrocele fluid mixed with one-third its volume of glyose bouillon. After twenty-four hours the surface of the medium was found to be covered with a thick white growth, composed chiefly of bacilli. A small particle of this growth was diluted with bouillon, and cultures were made from this on hydrocele fluid. In this way isolated colonies of the bacillus were obtained.

Cultures of the organism were afterward made on agar, gelatine, pepton bouillon and Löffler's diphtheria serum-agar.

The bacillus is motile, delicate and short; thinner than the diphtheria bacillus; and not more than one-third or one-half as long. The length is from 0.8 to 1.7 μ , and the width from 0.3 to 0.4 μ .

The organism is apparently identical with the one described by Afanassjew, except that Koplik was unable to find spores. The organism is pathogenic for white mice in small doses (0.5 c. c.) of fresh cultures or in larger doses of old cultures, without, however, producing characteristic lesions. Subcutaneous injections in guinea-pigs and rabbits were attended with negative results. Intravenous injections in rabbits produced pyemia and joint lesions.

No lesions were produced in the lungs, and no characteristic convulsive symptoms were produced. The writer states that the number of experiments was too limited to permit conclusive deductions to be made. A few experiments with direct inoculation of sputum in guinea-pigs and rabbits produced no effect.

The author's summary is as follows: In 13 out of 16 cases of pertussis a bacillus was isolated from the sputum which agreed in all essentials with the organism described by Afanassjew. The difficulty of obtaining a suitable culture medium and the use of cases complicated with bronchitis and pneumonia may

readily account for the lack of success hitherto. The writer cannot state positively the rôle played by the organism in the production of pertussis; but from the constancy and number of the organisms in his cases, he believes that their importance must be admitted. The experiments on animals are thus far unsatisfactory.

SERUM REACTION OBTAINED FROM THE BLOOD OF AN INFANT AT BIRTH WHOSE MOTHER HAD HAD TYPHOID FEVER DURING PREGNANCY.²

Mossé and Dennie describe the following case: A woman, twenty years of age, contracted typhoid fever during the sixth month of pregnancy. Three months later she gave birth to a normal child. During the mother's convalescence the serum reaction was obtained from the blood and from the colostrum. The placental blood gave a marked Widal's reaction, as did also the milk twenty-four hours after the completion of labor. Blood taken from the umbilical vein of the infant gave a positive reaction, and caused agglutination in from one to two hours. The placenta was normal.

ON THE VALUE OF THE BACTERIOLOGICAL EXAMINATION OF URINE FROM AN ETIOLOGICAL STAND-POINT.³

F. Chvostek and Gust. Egger have made an investigation the purpose of which was to determine if in cases of so-called "heterologous bacteriuria" bacteria which are normally present in various organs obtain access to the circulation and are excreted by the kidneys. The writer's conclusions are based upon bacteriological examinations of the urine from a limited number of cases in which paroxysmal rises in temperature occurred not dependent upon bacterial infection (malaria and tuberculin injections).

In two cases of malaria, bacteria were found in the urine during a paroxysm. In three cases which were injected with tuberculin, bacteria appeared in the urine coincident with the rise in temperature and disappeared from the urine after the temperature had reached normal.

The authors conclude that in consequence of the increased temperature, micro-organisms obtain access to the circulation from organs in which they are present normally, and that owing to the diminished resistance of the tissues caused by the action of toxins, the high temperature, and the diminished germicidal power of the tissues and fluids, living organisms are excreted by the kidneys. Only when specific organisms are found in the urine is it permissible to draw conclusions as to etiology (typhoid, actinomycosis, tuberculosis).

It is more difficult to determine the etiological value of other organisms, namely, staphylococcus.

THE INFLUENCE OF COLD UPON THE SUSCEPTIBILITY TO INFECTION.⁴

Fischl gives the results of his experiments upon rabbits to determine the value of cold as a predisposing factor to infection. The rabbits were subjected to cold by confining them in tin receptacles surrounded by ice. In from one-half to three-quarters of an hour

the rectal temperature sank ten degrees Centigrade. This produced partial paralysis, slowing of the heart's action, tremors, and for a short time anuria. Recovery from this condition occurred within an hour. As soon as the temperature reached its lowest point the animals were inoculated in the edge of the ear with a culture of pneumococcus. Smaller rabbits which had not been subjected to cold were injected with an equal quantity of the culture at the same time. The infectious material consisted of a very weak culture of the diplococcus pneumoniae in serum, or ascites bouillon. This is an organism to which rabbits are very susceptible. Sixty rabbits were inoculated in this way, thirty of them being used for controls.

In ten cases, neither the animals subjected to cold nor the ones used for control showed symptoms of infection. In two cases, the animals subjected to cold showed symptoms of pneumococcus septicemia but recovered; the control animals showed no symptoms of infection. In three cases, the cooled animals died; the control animals remained well. In ten cases, the cooled animals died of pneumococcus septicemia; the control animals showed a moderate elevation of temperature and pneumococci in the blood, but recovered. In five cases, the cooled animals died sooner than the control animals (virulent cultures). The anuria lasted but a short time and no severe lesions were found in the kidneys of any of the animals; consequently this condition cannot be considered as the cause of the retention of the organisms in the system.

The leucocytes appeared to play an important part in favoring recovery from infection. One of the cooled animals, and all of the control animals which showed symptoms of infection, but recovered, had leucocytosis. There was no leucocytosis in the cooled animals which died and in one of the control animals that died. There was no leucocytosis in the animals in which there were no evidences of infection.

PATHOLOGY OF THE THYMUS GLAND.⁵

Siegel reports the case of a child two and one-half years old who developed what appeared to be asthma which developed into a permanent dyspnea, associated with suffocative attacks. Tracheotomy was performed, but gave no relief to the patient. A canula was introduced, which extended to the bifurcation of the trachea. This also gave but little relief.

When the patient had been two months under observation, the mediastinal space was opened, into which the thymus gland protruded with each inspiration. The partially detached thymus was then pulled forward as far as possible and attached to the fascia of the anterior mediastinum. The breathing became quiet at once, in spite of the removal of the canula. The child improved rapidly and six weeks after the operation she was declared cured.

A STUDY OF THE ETIOLOGY AND HISTOLOGY OF PNEUMONIA OCCURRING IN CHILDREN, ETC.⁶

The purpose of this article by Dürck was to determine what varieties of bacteria are present in children's lungs in cases of primary and secondary pneumonia and their etiological importance.

In the first part of the article the author gives the results of the bacteriological and histological examinations of the lungs from 41 cases of pneumonia.

In two of the cases the cultures and inoculative experiments were negative. In the remaining cases he found the diplococcus pneumoniae 33 times; streptococcus pyogenes 14 times; staphylococcus 21 times; Friedländer's pneumonia bacillus 12 times; the diphtheria bacillus 11 times; the colon bacillus twice; and sarcina and yeast fungi eight times. In 34 of the cases mixed cultures were obtained (see original article for the varieties).

In the cases of secondary pneumonia nothing worthy of note was discovered by means of the bacteriological examinations regarding the connection of the primary disease with the pneumonia, except that the diphtheria bacillus was found only in cases of post-diphtheritic pneumonia. The colon bacillus was found in one case of gastro-enteritis and in one case of syphilis.

The variation in the histological appearances of the exudation were not characteristic of any particular variety of micro-organism. Giant cells were found, especially in cases of post-diphtheritic pneumonia, in cases which had been treated with Behring's antitoxin. According to the author's view, the softening of the membrane in the trachea and larger bronchi, which tends to produce aspiration of the softened material, favors giant-cell formation. (?)

The second part of the article is devoted to a bacteriological and histological study of the lungs from 13 children who died of various diseases other than pneumonia. All of these cases showed the presence of bacteria in the lungs, although the histological examination showed an entire absence of inflammatory exudation. In one of the cases Friedländer's pneumonia bacillus was found and in the remaining twelve cases mixed cultures of the diplococcus pneumoniae, streptococcus, staphylococcus and the colon bacillus were obtained.

For purposes of control, the author examined the lungs of 10 pigs, two horses, two oxen and a calf, and in 14 of the 15 animals found bacteria present in considerable numbers, namely, the pneumococcus, pneumonia-bacillus, etc. In the pigs' lungs, he found a bacillus about the size of the anthrax bacillus, which he was unable to study further. In conclusion, the writer reports the results of a number of experiments on animals.

Cultures of streptococcus, staphylococcus and pneumococcus were sprayed into the lung of rabbits through wounds in the trachea, for the purpose of producing pneumonia. The results were negative in all cases.

In a second series of experiments the above procedure was modified by introducing into the lungs a small quantity of sterilized dust either before or after spraying in the cultures. In all cases areas of focal pneumonia were produced. When dust alone was sprayed into the lungs, the same lesions were produced as when combined with the cultures, if the dust was deleterious. Street-dust was borne in quite large quantities without producing pneumonia.

In a final series of experiments the effects of exposure to cold was tried. Animals were kept for from sixteen to thirty-six hours in a thermostat at a temperature of 37° C., and were then suddenly immersed for from two to seven minutes in ice-water.

⁵ Jahrbuch f. Kinderheilk., Bd. xlv, H. 3, 4; Archives of Pediatrics, November, 1897.

⁶ Deutsch. Arch. f. Klin. Med., Bd. lviii, p. 368, 1897; Centralb. f. Bacteriologie, etc., Bd. xxii, July 20, 1897.

In a limited number of cases, without exception, pneumonia was produced which differed in no respect from the croupous pneumonia of human beings. In three of the cases the colon bacillus was found; in one case Friedländer's bacillus, and two cases could not be examined.

The author's summary is as follows: A more or less complicated mixed infection is found in the primary and secondary pneumonias of children. The diplococcus pneumoniae is found more frequently than the other varieties of micro-organisms. With the exception of the cases of post-diphtheritic pneumonia, the cultures showed no evident connection between the primary disease and the pneumonia.

The normal lungs of children contain bacteria, among which the pneumococcus is most frequently found. The lungs of recently killed animals contain pathogenic organisms. The mere presence of bacteria is, however, not sufficient to produce pneumonia. Some immediate injury to the lung tissue is essential.

The pneumonias produced by dust and exposure to cold are due to injury of the lung tissue, which prepares the way for infection by the bacteria which are present. Cold acts probably by producing an intense acute hyperemia of the lung.

The presence of pathogenic organisms in the normal lung suggests an explanation for the occurrence of secondary infections in connection with tuberculosis.

New Instruments.

A LOCK FOR THE REYNOLDS AXIS-TRACTION RODS.¹

BY F. A. HIGGINS, M.D.,
Assistant in Obstetrics, Harvard Medical School.

This lock was devised to prevent the annoyance and delay occasioned by the slipping off of the traction rods after the obstetrical forceps is applied to the child's head, which frequently occurs in skilled as well as unskilful hands.

It may be adapted to any obstetrical forceps by a good mechanic at very little expense, without refinishing and replating the forceps, and also without altering the traction rods themselves.

The lock is constructed by drilling a small hole, one-quarter of an inch in diameter, midway in the forceps blade, three-eighths of an inch below the narrow end of the fenestra, and by filing a narrow slot through from the end of the fenestra to this drilled hole. As the shaft of the traction rod is narrowest at the tip, it readily slips through the slot when held out at right angles, and then when dropped it remains locked in position and freely movable.

The construction of this lock on the forceps does not prevent the application of the traction rods in the old way, after the forceps is on the head, although the rods cannot be locked at this time.

I believe this device may at times render an extra assistant unnecessary.

A DOCTOR AS MAYOR-ELECT OF BUFFALO.—Dr. Conrad Diehl, a physician of thirty years' standing in Buffalo, N. Y., has recently been elected Mayor of that city by a large majority.

¹ Read, by invitation, before the Obstetrical Society of Boston, October 19, 1897.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

REGULAR Meeting, October 19, 1897, the President, DR. FRANCIS H. DAVENPORT, in the chair.

DR. W. L. BURRAGE read on

DIVISION OF THE UTERO-SACRAL LIGAMENTS AND SUSPENSIO UTERI FOR IMMOBILE RETROPOSITION WITH ANTEFLEXION,

of which the following is an abstract:

Immobile retroposition with antelexion is defined as a uterus placed as a whole in the back of the pelvis and so changed from the normal in shape as to be bent forward either in the neck, in the body, or in both and at the same time impossible of replacement. Such a pathological condition of the uterus is, in the experience of the writer, commonly associated with a greater or lesser degree of shortening and thickening of one or both utero-sacral ligaments, in a majority of cases with prolapse and enlargement of one or both ovaries and almost invariably with endometritis.

The condition coincides very nearly with what B. S. Schultze calls Pathological Antelexion, and the views of this authority are quoted at length in support of the writer's contention that the condition is largely the result of extra-uterine causes rather than changes in the wall of the uterus itself: that the condition is, in many cases, a persistence of one or more characteristics of the infantile or puerile uterus and is not a congenital affair.

The writer does not believe in the obstructive dysmenorrhea theory, but considers that the dysmenorrhea from which patients with retroposition with antelexion suffer is due to the uterine engorgement, with its accompanying endometritis and the inability of the uterus to become relieved of its congestion.

The pathology of this affection has not been satisfactorily determined. The cases due to tubo-ovariitis, following labor and abortion, and from adhesions posterior to the uterus from old hematocele, are easier to explain than those occurring in virgins without previous history of inflammatory attack and showing no appreciable traces of past inflammation in the peritoneum.

The treatment of fixed antelexion with retroposition has always been one of the difficult problems in gynecology. It is probable, that, if pregnancy supervenes before the tissues of the uterus at the point of flexion have become hardened or atrophied, and before the endometritis has gotten well settled in the uterus, that the flexion will be lastingly removed and the utero-sacral ligaments permanently stretched, in a majority of cases.

The pelvic congestion, which stands in a direct casual relation to the symptoms of dysmenorrhea, pelvic pains, bladder irritability, etc., is to be relieved by hot douches, tampons, vaginal suppositories, electricity, massage and, in the obstinate cases, by curetting and gauze drainage. Too often these measures give only temporary relief.

Packing the vagina to stretch the utero-sacral ligaments has been abandoned as ineffectual. Schultze's forcible massage with the patient anesthetized, for the same purpose, is thought to involve too much risk to the ovaries and tubes. Dudley's operation for ante-

flexion is wrong in principle, because it does not seek to do away with the cause of the deformity, the traction exerted by the utero-sacral ligaments. The Alexander operation on the round ligaments, intra-abdominal shortening of the round ligaments, and suspensio uteri, are by themselves contraindicated because of the fixed condition of the uterus.

The author's method of treatment is one he devised for the intractable cases — those that do not yield to the ordinary modes of treatment. It is, in brief, as follows: Dilatation of the uterine canal with curetting, and abdominal section. A short incision is made; the utero-sacral ligaments are put on the stretch and divided in sight at the points where they have the posterior uterine wall; the uterus is suspended to the parietal peritoneum and transversalis fascia by sutures of chromicized catgut, passing through the anterior face of the fundus; and the abdominal wound is closed by layer suturing of the same material.

The cases numbered nine, the operations having all been done in the last few months, and the results were offered at this time, not as indicating final conclusions on the subject, but as suggesting a promising means of treating a hitherto baffling class of cases.

In the cases of retroposition with ante flexion, where the ovaries are quite normal to the feel and normally placed with reference to the uterus, the author prefers to perform the Alexander operation on the round ligaments, after having first divided the shortened utero-sacral ligaments by a posterior colpotomy and rolling each ligament into view in the vagina on the operator's finger. As a rule, one or both ovaries are prolapsed or cystic degenerated. The Alexander operation is, as a rule, not effective in restoring a displaced ovary to its normal position. This the writer accomplishes by taking a reef in the ovarian ligament. As to the steps of the operation, the chief interest centres in the division of the utero-sacral ligaments and in the method of suspension.

For dividing the ligaments, careful preparation of the patient as to the bowels is of supreme importance. In very stout women and in those patients in whom by previous insufficient preparation the intestines are inflated with gas and the intra-abdominal pressure correspondingly great, division of the utero-sacral ligaments by sight is an extremely difficult procedure.

To divide the ligaments a broad, flat spatula in the hands of the assistant — the patient being in the Trendelenburg posture — holds back the ganze-covered intestines; and the utero-sacral ligaments, put on the stretch by the uterus, held well up by means of a carrying thread passed through the anterior fundus, are brought into view. They are seen as two tense, white bands coming from the pelvic wall at the region of the second piece of the sacrum and meeting on the posterior aspect of the uterus in the form of a pointed arch with its apex at about the level of the internal os. Each ligament is cut with a knife at the place where it leaves the uterus, by a small incision at right angles to the long axis of the ligament. The toughness of the structure of many of the ligaments has been a noticeable feature, and they cut as if made of fibrous tissue. The uterus, freed from behind, springs forward, and a lozenge-shaped raw surface is left where each ligament is divided. These raw surfaces may be covered with peritoneum by two or three transverse stitches of catgut, or left as they are if, as usual, they are small. There is generally little oozing.

Cutting the ligaments by touch instead of by sight is not safe. By attaching the anterior surface of the fundus to the parietal peritoneum the direction of the intra-abdominal pressure on the body of the uterus is altered from a faulty to a more normal one.

When the patients were examined at the end of three weeks, it was found that in every case the uterus was suspended in good position in the pelvis, the ovaries were in good position, the cul-de-sac free, primary union in the abdominal incision and the flexion nearly (or quite) gone from the uterus.

Time and observation alone will determine the remote anatomical and symptomatic results. The immediate results leave little to be desired.

DR. A. D. SINCLAIR spoke of the very unsatisfactory methods of treatment formerly employed for this condition. The operation, as described, appealed to him as very rational, and he complimented the reader on his success.

DR. M. STORER said that the usual treatment of packing and massage is often discouraging. He has curetted and suspended the uterus, but has not divided the ligaments as described by Dr. Burrage. In one case of his he felt a distinct giving way, which was no doubt a subperitoneal rupture of the ligaments.

DR. EDW. REYNOLDS said that there were cases among the working classes where an immediate operation for this condition is demanded as the women cannot afford the time. In other circumstances, however, he should not feel justified in subjecting the patient to such a severe operation for a comparatively slight affection.

DR. G. J. ENGLEMAN objects to the operation of suspension especially in women of the child-bearing age. If possible he should much prefer to cut the ligaments and free the uterus, but not suspend the uterus.

DR. F. H. DAVENPORT spoke of a case he operated on where the utero-sacral ligaments were abnormally placed so far posteriorly that he could not suspend the uterus until he had divided the ligaments. In his experience retroposition with ante flexion was an unusual form of displacement.

DR. EDW. REYNOLDS said that he had obtained entire relief from symptoms in these cases by freeing the cervix and allowing it to go back.

DR. W. L. BURRAGE said, in reply to Dr. Davenport, that in his experience cases of retroposition with ante flexion were very common. It was treating a large number of these cases in the out-patient department of the hospitals, and following the cases up from month to month and from year to year, and noting that many were not relieved even after curetting, that led him to adopt the operative procedures described in the paper of the evening. The operation is only intended for the obstinate cases that are not relieved by less vigorous measures. As yet it is too early to speak of the permanent results. He did not fear any bad effect of suspension of the uterus by means of absorbable ligatures applied to the anterior surface of the fundus uteri.

The recent trend of opinion on this subject would tend to prove that dystocia during labor following ventral fixation was due to the fastening of the posterior surface of the fundus with permanent ligatures to the fascia and muscles of the abdominal walls. As the uterus developed in size the anterior segment became incarcerated behind the pubes. He followed Dr. Charles P. Noble in his ideas on this subject, and

drew a sharp distinction between ventral fixation and suspensio uteri.

The attachment of the anterior face of the fundus was necessary in antelexion in order so to direct the intra-abdominal pressure as to remove the flexion. The manner in which uteri became straightened following this operation was little short of marvellous.

In regard to Dr. Englemann's position, that division of the ligaments alone would be sufficient to restore the uterus to its proper position in the pelvis, he thought the anterior supports of the uterus had become so weakened in cases of immobile retroposition with antelexion that suspension as well as division of the utero-sacral ligaments was necessary.

DR. EDW. REYNOLDS reported

A CASE OF OÖPHORECTOMY DURING LABOR.¹

DR. W. E. BOARDMAN referred to cases where the tumor obstructed labor in an apparently hopeless way, but were finally delivered in the natural way after the drawing up of the tumor. He thought longer delay in the case reported might have been followed by this result.

DR. J. B. SWIFT, referring to the difficulties of exact diagnosis in these cases, spoke of a case thought to be fibroid complicated with pregnancy which disappeared after the child was born. Six months later she was thought to be pregnant but a tumor was found which was decided to be fibroid and the diagnosis was confirmed by two good physicians in New York. This diagnosis was also made in Europe, and non-interference was advised by all. Coming back to Boston, the position of the tumor had changed, operation was advised and a dermoid cyst removed.

DR. F. A. HIGGINS exhibited, by invitation

A LOCK FOR THE REYNOLDS AXIS-TRACTION RODS.²

NEW YORK NEUROLOGICAL SOCIETY.

MEETING of October 5, 1897, DR. B. SACHS, President.

A CONSIDERATION OF THE PARESTHETIC NECROSES, PSYCHROESTHESIA AND KAUMESTHESIA.

DR. C. L. DANA presented a paper with this title. He said that paresthesia included nearly all the subjective sensations of the skin except those of pain. When these sensations fastened themselves to a particular part, as a nerve, they developed a definite picture, and were as much entitled to a distinctive name as was neuralgia. Sometimes paresthesias of the head caused sensations of burning, pressure and cold, which were entirely comparable to headache. They affected the cerebro-spinal nerves just as did neuralgias. The cephalic paresthesias were usually symptomatic of a lithemic state. The most frequent causes of local paresthesias were those concerned with occupations. Women were affected more frequently than men. The feet and legs were most affected; next the hands alone, and next the hands and feet together. The nerves most affected were the brachial and their branches. The most common form of paresthesia was a sensation of tingling or numbness; more rarely there was a sensation of heat. Among the rarest forms

of paresthesia were sensations of cold, which were entirely apart from an actual lowering of the temperature of the part, and which occurred without any objective vascular changes. This form was not usually very distressing. The term "psychroesthesia" was first applied by a French physician in 1886. The reader of the paper said that he had himself met with a number of those cases, of which the following were illustrations:

CASE I. D. C., a washerwoman, had suffered from chronic tinnitus for three years, and had some disease of both middle ears. She complained especially of a cold sensation which she had felt continually in the forehead for three years. The sensation was bilateral, and involved the upper part of the forehead. The skin was not cold to the touch, nor did it appear in any way abnormal. Examination revealed no anesthetics, and no signs of organic disease.

CASE II. A man, fifty-six years of age, a mechanic. He was compelled to stand all day at his work. For a year and a half he had had some paresthesia of the lower part of the legs, and had also suffered from a distressing sensation of cold in the feet. The physical examination showed absolutely no anesthesia of the affected part, and no change in vascularity. The reflexes were slightly exaggerated.

CASE III. A man, forty-two years of age, a butcher, whose previous history was negative. He complained of a sensation of cold over the left thigh, particularly over its anterior surface. This sensation had been continuous for the past six months, and was increasing in severity. There were absolutely no objective signs over the affected part. The man was a dyspeptic.

None of the cases, the speaker said, was an example of beginning or terminal alcoholic neuritis, in which paresthesias are so common. He had noted particularly two classes of cold anesthetics, namely, one, not definitely limited to certain areas, but involving the whole extremity or all four extremities; and the other, to which the name psychroesthesia proper should be given. The former was associated with pain or vasc-motor disturbance, and was due to irritation of the peripheral nerves; it indicated an abortive type of degenerative neuritis. Cold sensations were very rare when neuritis was marked, as in alcoholic neuritis. Such diffuse cold sensations also occurred in syringo-myelia, and in lesions of central gray matter of the spinal cord. The second class represented a disease in which the patient suffered from a sensation of cold exclusively, there being no associated tingling or prickling. It was usually confined to some small area. These patients felt as though some cold object were lying upon the part. These sensations were usually of traumatic origin, and were associated with lithemia, and with the degenerative changes of middle life. In his experience, they had occurred more often among men than women. Apparently, the cold paresthesias were not produced by lesions of any of the sensory neurons, that is, by any lesions above the spinal cord, nor did they seem to be produced by lesions of the spinal ganglia. The only two conditions in which cold sensations were found were: (1) lesions of the central gray matter, possibly involving the terminals of the first sensory neuron or the beginning of the second sensory neuron, for example, in beginning syringomyelia; and (2) in lesions of the peripheral sensory nerves. They must

¹ See page 647 of the Journal.

² See page 652 of the Journal.

be due to lesions of the very terminal portions of the peripheral filaments. The pure types of psychroesthesia he considered to be always due to irritation of the peripheral filaments, and that the cold paresthesia found in tabes and various lesions of the spinal cord were always mixed pains.

DR. WILLIAM H. THOMSON said that he had a case to report which was not in harmony with Dr. Dana's decision with reference to the central relations of psychroesthesia. On March 7th, a gentleman, fifty-one years of age, had called upon him, stating that he had awakened the night before with a sensation of "universal numbness" over his right side. It involved the face, right arm and legs, and the numbness was accompanied by a prickling sensation, and by a binding sensation just above the right knee. The pulse was 94 and of high tension; the artery was somewhat thickened; there was no real anesthesia to pain. There was a decided increase in the knee reflex on the right side. There was no aphasia or deviation of the tongue. His special complaint was a sense of coldness distributed over the shoulder and down the arm, involving the fingers and back of the hand, but more particularly the leg and foot. The urine showed no albumin or casts. The case was kept under observation until June 4th. At that time it was noted that there was the same distribution of the cold sensation, except in the face. There was also a pronounced redness of the skin extending from the crest of the ilium to the knee, but quite as marked on the other extremity as on the affected side. The speaker said that the lateral distribution, involving the face, seemed to be an exception to the cases reported in the paper.

DR. GEORGE W. JACOBY thought Dr. Dana was right in ascribing many of the one-sided paresthesias to neuritic conditions, but he was of the opinion that the symmetrical paresthesias were due to some general condition—one which exerted an influence on the central gray matter of the spinal cord. This general condition was usually a toxemia of some kind—quite commonly an auto-intoxication from the intestines. He had seen a number of examples of paresthesias resulting from the inordinate use of tobacco. In these cases there was a general feeling of heat extending down one or both arms, along the distribution of the ulnar, and such a paresthesia was to him almost symptomatic of tobacco poisoning as the etiological factor. Another characteristic parasthesia was a sensation of heat or tingling passing along the penis and into the scrotum; and a third was a paresthetic condition distributed along the inner part of the thigh, usually symmetrically. These three paresthesias he had found very frequently in persons using tobacco to excess, and they had disappeared after the use of tobacco had been *entirely* given up.

DR. C. A. HERTER said that he had met with several instances of paresthesia of cold in which the distribution was somewhat different from that mentioned in the paper. For example, he had twice met with paresthesia on the abdomen, and also upon the chin. He agreed with the reader of the paper in ascribing most of these cases to peripheral irritation of nerves, but whether this irritation depended upon auto-intoxications was a matter about which we could not speak very certainly as yet. In one of his cases there had been an actual lowering of the surface temperature of about one degree, as compared with

the other side. He could not say whether or not this was a common feature.

DR. WILLIAM HIRSCH said that these cases were in all probability due to peripheral lesion, or were cases which had developed as a result of chronic alcoholism. He had seen four cases (including one he had already presented to the Society) in which trauma had acted as an exciting agent. One patient, while travelling, had carried another passenger in his lap for a long time. Following this he had developed a paresthesia of the thigh. Another patient, also a sufferer from chronic alcoholism, had experienced trauma in the upper portion of his thigh. More than one of them had noticed on taking a hot bath that the part complained of did not feel heat with the normal acuteness.

DR. W. M. LESZYNSKY said that he had seen three cases, all in persons nearly fifty years of age. One was a man with general atheroma, who had a large area of cold sensation over the lower part of the leg. He was given nitroglycerin, and the sensation disappeared. In another case, the cold feeling existed for a long time, and then was succeeded by a sensation of heat. Subsequently the hot and cold sensations alternated. In still another case, the urine was of high specific gravity, and contained indican in excess. One of these last two cases improved decidedly.

DR. A. D. ROCKWELL asked if Dr. Dana included among his cases these paresthesias which result from acute diseases—for example, typhoid fever—for he could recall a great many instances of paresthesia following such acute diseases.

DR. FRAENKEL said that he had examined the sensory disturbances in tabetics, paying particular attention to temperature paresthesia. Out of 36 tabetics, only two had cold paresthesia. One complained constantly of a cold sensation along the back and down the legs; the other complained of cold paresthesias along the back part of the legs and the extensor surfaces of the upper extremities. The general appearance of this case was rather that of cerebro-spinal syphilis, and the condition appeared to be the result of some meningitic pressure. There was no disturbance of the temperature sense in these cases. The last case he would explain by pressure on the posterior horns simply.

DR. LEOPOLD STIEGLITZ had seen some paresthesias of the temperature sense—one very marked one in a case of multiple sclerosis. The patient had been under his observation for five or six years, and had suddenly begun to complain of a sensation of cold extending from the umbilicus down through both legs, as if he were standing in cold water up to the waist. This sensation lasted about two weeks, and then gradually wore off. Following this were occasional sensations of cold in one or both extremities. Probably in this case it was the result of transient disturbances in the circulation in the spinal cord. The examination of the patient at first showed a diminution of sense of cold, much more than of heat. He did not think all the cases were due to peripheral neuritis; in some the paresthesia seemed to be an early symptom of tabes.

DR. J. F. TERRIBERRY said that, inasmuch as tobacco was supposed to play such a small part in the peripheral sense apparatus, outside of the optic nerve, he had been deeply interested in the remarks of Dr. Jacoby. It was well known that under certain circumstances tobacco was a decided depressant, and an

excitor of dyspepsia, and it was possible that it acted indirectly in this way by causing auto-intoxications.

The PRESIDENT said that he had seen a number of the special forms of pure paresthesia described in the paper. One case was that of a physician, thirty-five years of age, who had been moderate in his habits, yet ever since his student days had had a sensation of cold on the inner aspect of the left thigh. This was aggravated by severe exercise but not influenced by changes in the weather. The examination was entirely negative, and treatment had no effect. The speaker said that he had been particularly troubled with a class of cases with a persistent burning sensation in the heel. This was not affected by exercise or by posture, or by treatment, either surgical or medical. He thought these cases were generally due to some lithemic or gouty condition; he had suspected osteitis or periostitis in some cases.

DR. DANA, in closing the discussion, said that the more pure the cold paresthesia, the surer might one be that it was a lesion of the peripheral nerves and terminal filaments. In some of his cases, similar to that described by the last speaker, there had been originally an eczema or some slight form of trauma, which had ultimately become a mere dermal hallucination. Regarding the case reported by Dr. Thomson, he said that it compelled him to admit that these paresthesias might be caused by central brain lesions as well as by peripheral lesions. He could confirm Dr. Jacoby's statements regarding the effect of tobacco, for he had seen obstinate and distressing paresthesias of the hand, which disappeared very promptly on giving up the tobacco. The authors that he had consulted had not made systematic observations of the temperature of the skin. In reply to Dr. Rockwell he would say that after pneumonia and typhoid fever he had only seen the general anesthetics such as were observed in the mild types of neuritis. He had some experience with the troublesome cases of "burning heels," and had come to believe that many of them, at least, were due to a certain degree of traumatism, resulting, perhaps, in periostitis.

STATED Meeting November 2, 1897, DR. C. A. HERTER in the chair.

THOMSEN'S DISEASE.

DR. GEORGE W. JACOBY exhibited a typical case of Thomsen's disease. The patient, a young man, had been referred to him by Dr. Schwinn, of West Virginia, with a correct diagnosis. The patient was twenty-eight years of age, and had lived in this country since 1884. There was nothing in the family history bearing upon the condition especially, except that a distant cousin was said to have walked stiffly and in a peculiar manner for fifteen years. The patient himself had always been delicate, but had been as active as other boys. He had had typhoid fever in 1889, and on recovering from this had first noticed a cramp in the legs. After a little while it was found that he could not execute movements as quickly as before. In 1893 he first sought treatment. For the past year or two his arms and hands had also been affected. The condition varied considerably at different times, but was apparently not affected by meteorological changes. The examination showed quick reaction of the eye muscles, with spasm of the external rectus; cramp of

the masseter muscles on bringing the jaws together forcibly; no involvement of the pterygoids. All the muscles of the upper extremity and of the thorax were involved — indeed, nearly all the muscles of the body. The contraction of the muscles was decidedly tetanic, and was very marked at first, but, on repeated tests, it gradually subsided. The electrical examination showed marked myotonic reaction, and also a wave-like appearance, but he could not make up his mind that this latter phenomenon consisted of a series of waves, such as are observed in water. A piece of muscle had been excised from the biceps, and also from the quadriceps, but they had not yet been minutely examined. The case was quite characteristic on account of the marked variations occurring from time to time. The speaker said that in an article published by him ten or more years ago he had taken the stand that these cases were probably of myopathic origin, due to some congenital defect in development; but in the light of modern investigation he was now disposed to believe that some central cause was at work — that there was a functional hereditary derangement of the central nervous system, a condition of lessened resistance in the cells. This did not seem to him a strange assumption, when one considered the well-known idiosyncrasies exhibited to various toxic influences. On the theory that some kind of toxemia was at the foundation of this disease, he thought the observed phenomena could be explained — at least, in this direction seemed to lie the possibility of solving the pathogeny of this class of cases. This patient had not been affected by the disease until eighteen years of age; hence, there was no propriety in calling such a case "myotonia congenita." He would divide these cases into three classes, namely, (1) myotonia congenita, (2) myotonia acquisita, and (3) myotonia transitoria.

DR. FREDERICK PETERSON asked why a theory of causation might not be founded upon chemical changes in the muscles. Changes in the structure of the muscles, he said, were known to arise, for instance, in connection with typhoid fever.

DR. HERTER thought that we must look to toxic agents as furnishing at least a clew to the causation of such conditions. The peculiar susceptibility to certain types of poisons, seen, for instance, in epilepsy, must be referred to peculiarities of the central nervous system. He would agree with Dr. Peterson that these cases did not seem to be of central origin, and that it was more probable that they arose from chemical changes in the muscles. To study this subject successfully, it would be necessary to inquire into the condition of the secretions and excretions at the time of the onset of the disease, and not after it had become chronic.

PACHYMENINGITIS HEMORRHAGICA INTERNA IN CHILDREN.

DR. C. A. HERTER said that internal hemorrhagic pachymeningitis was usually considered to be a very rare condition in children, yet one German observer had found it in about 17 per cent. of his autopsies. The following cases were reported:

CASE 1. A female child, five and a half months old, was admitted to the Babies' Hospital on May 15, 1897, with an entirely negative family history. The child's illness had begun one month previously with persistent vomiting. The head was of normal shape, and the

fontanelles were not bulging. There was a soft spot over one parietal bone. The child had no teeth. On the fifth day after admission tremor and nystagmus developed. Nine days after admission there was a general convulsion, in which the mouth deviated to the left. Cyanosis was a feature of the convulsion. A second one occurred in ten hours. After these seizures the fontanelles were sunken. The child now became semi-comatose, and died after a few days. The autopsy showed the presence of hemorrhagic pachymeningitis, fibrino-purulent pleurisy, pulmonary congestion, fatty liver and nephritis. Along the superior longitudinal fissure, over the entire base and over the island of Reil on both sides was a membrane covering the pia. The ventricles were normal in size, and contained about one drachm of hemorrhagic fluid. There was fluid blood in all the sinuses. The cervical cord showed the same conditions. Under the microscope the right occipital region showed the pia attached to the cortex in many places, and there was a splitting up of the membrane overlying the cortex into two or more layers. The inner layer was infiltrated with small round cells. The outer membranous layers consisted of small round cells, fibroblasts and connective-tissue fibres. The island of Reil showed the same condition, but much more marked, and about the same condition was present over the cerebellum. In the spinal cord there were only slight traces of hemorrhage.

CASE II. Female infant, colored, twenty-two months old. The child had been nursed for seven months. It had never walked or stood alone, and was markedly rachitic. The first two months in the hospital were marked by slight loss in weight and considerable prostration. In October, 1897, the child was readmitted, with the statement that she had been well up to three days before, at which time she had had four convulsions, followed by three more the next day. The general condition was very bad. The hands and feet were in a position of persistent flexor contraction, characteristic of tetany. The knee-jerks were unobtainable; the fontanelles were bulging. There was slight, but varying rigidity of the muscles at the back of the neck. Bloody mucous diarrhea was present, and the child died comatose. The autopsy showed pachymeningitis hemorrhagica interna, broncho-pneumonia and acute and chronic ulcerative colitis. Over the right side of the brain was a recent blood-clot covering the entire hemisphere, and over the left occipital lobe. The inner surface of the dura was covered with a membrane extending from the superior longitudinal fissure on either side. The pia was congested. The ventricles and brain substance were apparently normal. All the sinuses were filled with recent clots. The microscopical examination showed thickening of the pia over the right temporo-sphenoidal lobe, and the vessels of the pia were thickened. There was also a thick membrane splitting up into layers, as in the other case. There were numerous small blood-vessels, and hemorrhages had occurred into the meshes of the membrane. In places, there were aggregations of small round cells undergoing fragmentation. They were found chiefly in the superficial layers of the membrane. In the dura the fibres were separated from each other by serous infiltration, and the dura was covered with a membrane similar to that already described. In places, there was very extensive pachymeningitis.

It was at about five months of age, the speaker said, that this disease was especially frequent. The major-

ity of these infants were badly nourished, many of them being subjects of rachitis or of chronic colitis. The new membrane must be regarded as originating from proliferation of the dural endothelial cells. In some cases there was little inclination to hemorrhage. The membrane was very variable in thickness; sometimes it reached a thickness of two or three lines. It was especially prone to occur in the basal fossae. There seemed no good reason for thinking that the locality of the pigmentation indicated that the layer of blood originated from the inner surface of the dura. On the other hand, there was no conclusive proof of the old notion that the disease was of inflammatory origin. It was so common to find severe intoxications without such lesions, that the intoxication theory did not seem to him tenable. It was apparently impossible to recognize the condition until the hemorrhage occurred, and even then it was extremely difficult to make a positive diagnosis. Slight cerebral symptoms were probably masked in these very young and usually marantic children. The hemorrhage was probably more often unilateral, and the usual symptoms present were rigidity, hemorrhage and coma. Paralysis was rarely noted. The pyrexia was usually less than in meningitis, but these cases were so commonly complicated with other diseases that the range of temperature was very variable. He did not think there was any symptom or combination of symptoms in hemorrhagic internal pachymeningitis which might not be encountered in any acute infection without any cerebral affection being present; but whenever unilateral rigidity and convulsions, with deepening stupor, were present in a cachectic or rachitic child under one year of age, we should think of that diagnosis. It was probable that relatively slight traumatism to the head might occasion rupture of vessels in the highly vascular membrane. This gave these cases a certain medico-legal importance.

DR. PETERSON remarked that the condition was interesting to him because of the possibility of its being found occasionally in infantile cerebral palsy.

DR. HERTER said that he was inclined to think that these membranes were considerably more frequent than one would suppose from the literature. It was quite possible to overlook the presence of the membrane if it were not decidedly vascular.

THE PATHOLOGY AND MORBID ANATOMY OF HUNTINGTON'S CHOREA, WITH REMARKS ON THE DEVELOPMENT AND TREATMENT OF THE DISEASE.

DR. JOSEPH COLLINS said that the neurologist frequently encountered knotty problems, and among these none had the secret of its genesis more carefully concealed than the hereditary degenerative diseases. The pathogenesis of the acute inflammatory diseases of the nervous system was an open book, but the degenerative diseases were discouragingly slow in yielding the mystery of their being. This was especially true of such degenerative diseases as the hereditary ataxias, choreas and dystrophies. The status of the original lesion could not always be inferred from a consideration of the lesion found at the time of death, and this was particularly true if the disease had existed a great number of years. No one could do much laboratory work on the central nervous system of individuals who had succumbed to degenerative nervous diseases of long duration without having forced upon him the fact that there are certain abnormalities

of the circulatory system — varying degrees of degeneration of vessels, change in the size of the lymph spaces, and relative disproportion of glia tissue to the parenchyma — which occur with all degenerative diseases, considered entirely apart from their causation. He felt convinced that such changes were very often secondary, and had no other significance than as evidences of protracted disturbance of nutrition, and that this nutritional depravity was the result of the existence of the original lesion. There was nothing more certain than the occurrence of glia proliferation in all slowly progressing destructive lesions of the nervous system, but nothing could be more misleading than to consider this glia overgrowth to be primary, and the changes in the parenchyma secondary.

Huntington's chorea, Dr. Collins said, was a comparatively rare disease, and of rather recent recognition; hence, the reports made upon its pathology had not been uniform. The discrepancies were apparently the resultant of the varying points of view of different observers. In studying the nervous system in cases of Huntington's chorea it was scarcely justifiable to maintain that all the morbid conditions were inherent to the disease, for, as had been said, many of them might be the consequence of prolonged interference with nutrition. Although the present study of the pathology of the disease was upon an individual who had had the disease for a considerable time, it was compared with a case of much shorter duration reported by Dr. C. L. Dana. A study of these two cases, he felt confident, would go far towards establishing the morbid anatomy and hinting at the pathogenesis.

His patient was a man, fifty-five years of age, who had married in early manhood, and who was the father of three children — all of them giving evidence of neuropathic inheritance. The known duration of the disease in his case was ten years. At the beginning the hands only were affected, but in the last years the lower extremities were also involved. The mind remained in fairly good condition up to about three years before his death, when he began to have suspicious about his relatives and friends, and became forgetful and suicidal. His speech was so imperfect that in the last years of his life he was understood with difficulty. Dr. Collins had seen him for the first time a few days before his death. He then had a temperature of 105° F., and it remained at about this point until the end. The movements were very severe and incessant, except during sound sleep, although even then they frequently awakened him. He was quite conscious, but made no response to questions. The cause of death seemed to be exhaustion and high temperature. The disease was traceable to the maternal grandfather — an Irishman — who had three children, two of whom were affected with the disease. One of these was the mother of this patient, and of her seven children, five were afflicted with the disease. The other daughter had two children, one of whom became choreic. In three generations there had been no less than nine affected, and when it was considered that many of these children died in infancy, the number of cases that had developed was surprisingly great.

At autopsy, on opening the skull, the dura was considerably adherent, the diploë dense and the Pacchionian depressions marked. The brain had a wet appearance, as did also the cord. The pia was not

adherent to the brain. The convolutions of the anterior pole of the brain were very small, and the entire encephalon weighed 43½ ounces. The dura was intimately adherent to the spinal column. The principal fissures were somewhat wider and shallower and shorter than in the normal brain, but there was nothing pointing to defective convolutions. The average thickness of the gray matter was uniformly less than in the normal brain cortex, but this thinness could not be attributed here to age. An examination of the pons and medulla oblongata did not show any marked variation from the normal, but the changes were more noticeable lower down. Microscopical changes were not confined exclusively to the Rolandic region, but the process here was more advanced. The specimens were stained by various methods, and carefully examined.

The macroscopical changes were briefly as follows: (1) Thinness and atrophy of the cortex. (2) The mottled, streaked appearance and cribriform state on cross-section of the brain in the fresh state, due to diminution in number and in health of the ganglion cells, and to the increased perivascular and pericellular spaces and increased patency of blood-vessels.

The microscopical changes were: (1) A decay or slowly progressive degeneration of the ganglion cells of the cortex throughout the brain, especially of the two deepest layers, the layers of large pyramids and polymorphous cells. This cell death was particularly evident in the Rolandic region, very much less so in the anterior pole of the brain, and incomparably less in the posterior pole. (2) Increase of glia tissue, but not sufficiently prominent to constitute sclerosis, the conspicuous increase being about blood-vessels and ganglion cells. (3) Enlargement of the pericellular spaces and distention of the pericellular spaces. (4) Slightly diseased blood-vessels consisting principally of a proliferation of the nuclei of the adventitia and a thickening of the intima. This involvement of the vessels was not regular or symmetrical, but showed itself in certain sections of vessels only. (5) Relative paucity of the medullated fibres of the cortex. In short, it might be said, that the lesion was a chronic parenchymatous degeneration of the cortex, with consecutive and secondary changes in the interstices, the brunt of the disease having been borne by the motor regions. There was, in consequence, a degeneration of the pyramidal tracts in the spinal cord. In Dr. Dana's case the central convolutions suffered most, and the process occurred in patches throughout the affected cortex. There was nothing to justify the opinion that it was an inflammation — the process was evidently one of degeneration.

In connection with the treatment, Dr. Collins said that he desired to emphasize the necessity for delaying the advent of the disease in those who had a hereditary tendency to it, and also to emphasize the folly of tenotomy of the eye muscles — a method of treatment now being carried out upon one of these unfortunate individuals in this city, with a promise of a cure. If we wished to influence the course of hereditary chorea after it had once become manifest, it would be necessary to administer whatever drug was selected in the largest possible doses consistent with life, and to maintain this medication for a long time.

DR. ONUF said that he had been present at the autopsy on the case reported in the paper, and had been especially impressed with the general narrowing

of the gyri—a general atrophy. On section, the mottled appearance of the cortex had been most striking, but the cribriform appearance produced by the enlargement of the perivascular spaces was also worthy of note. The general appearance of the brain resembled very closely that of a brain from a case of general paresis. The microscope confirmed the macroscopical appearances, although the changes were not as marked as one would have expected from the gross appearance. The cell changes were of the atrophic order. The characteristic feature was the accumulation of neuroglia cells in the pericellular and perivascular spaces. His impression was, that this accumulation was due to a secondary process following atrophy of the cells. The disease was evidently a degenerative one, originating in the parenchyma of the brain, and not in the interstitial tissue.

Recent Literature.

Sexual Disorders of the Male and Female. By ROBERT W. TAYLOR. New York and Philadelphia: Lea Brothers & Co. 1897.

The profession is naturally prepared to give a cordial welcome to any work coming from so strong and well-known an authority as Dr. Robert Taylor. In the larger part of this work the author fulfils one's favorable anticipations. Its scope is limited to the consideration of the conditions, in both sexes, which interfere with, or prevent, the normal accomplishment of the sexual function. It is characterized by the clearness of statement, terseness and vigor which mark the previous writings of this author. The opening chapters deal with the anatomy and physiology of the parts. The chapter on anatomy does not seem to us to be as full or instructive as it should be. An example of this is the absence of any proper description of the fibrous investment of the septum of the penis or of the perineal muscles, fascia or ligaments. The parts selected for detailed description are those which are especially concerned as the most essential ones in carrying out the sexual function. Of these the portrayal is admirable.

A large part of the book is devoted to the consideration of impotence and sterility in the male; and a thorough discussion of the many causes which are the starting-points or lend to these conditions is included in it. Some interesting examples of the conditions causing organic impotence are quoted, amongst them are certain instances of ossification and fibroid sclerosis of the penis.

The chapter on chronic inflammation of the prostate is particularly instructive. That upon hypertrophy of the gland cannot be said to be adequate.

The latter part of the book deals with sterility in the female, some of the organic causes of which, as, for example, growths of the vulva, are interestingly illustrated by numerous well-reported cases and by prints.

The work seems to us deficient with respect to the treatment of some of the conditions it deals with, in that this part of the subject is often dismissed with a few words, or else only general principles are outlined; and hence we think it will be found more useful to those who are already more or less familiar with the subject than to students.

Appendicitis and its Surgical Treatment. With Report of Seventy-five Operated Cases. By HERMAN MYNTER, M.D. (Copenhagen), Professor of Operative and Clinical Surgery in Niagara University, etc. Pp. 303. Philadelphia and London: J. B. Lippincott Co. 1897.

This work is the publication of a monograph written by the author, and presented at Copenhagen to fulfil one of the requirements for a degree of Doctor of Medicine in Denmark. This demands that a thesis shall be presented showing special study and individual experience.

The writer has in this book tried to sift the evidence for and against the operative treatment of appendicitis, and has, after a careful study of a large number of foreign and American authors and statistics, concluded, as many other surgeons have also done, that appendicitis is a surgical disease and should be treated by surgical means, and that the physician is unable to prophesy the result in a given case, or prevent gangrene and perforation from resulting in a fatal peritonitis.

Part I opens with a historical review of appendicitis from 1759 to the present time. Then follow sections on Anatomy, Histology, Function, Etiology, Pathology, Classification, Symptomatology, Complications and Sequela, Diagnosis, Prognosis, Treatment and Statistics.

In Part II Dr. Mynter gives the clinical histories of 75 cases taken from his own records. These are classified according to age, sex, previous attacks, etiology, complications, kind of operation, gangrene, perforation, localized abscess, etc.

The writer has evidently given a great deal of time and thought to his work, and his book is an interesting contribution to the subject.

A Text-Book for Training Schools for Nurses. Including Physiology and Hygiene and the Principles and the Practice of Nursing. By P. M. WISE, M.D., Medical Superintendent, St. Lawrence State Hospital, etc. With an introduction by Dr. EDWARD COWLES. In two volumes. New York and London: G. P. Putnam's Sons. 1896.

The two small volumes before us are designed to cover the general subject of nursing, more particularly with reference to the insane. Dr. Cowles writes an appreciative introduction, in which he very properly calls attention to the need of skilled nursing in mental disease, a need of which has been too slow of recognition.

Dr. Wise has attempted to condense into the comparatively small space at his disposal a large number of facts bearing upon the principles of medicine as well as upon the principles of nursing. Such an attempt always has its accompanying dangers; it means, of necessity, superficiality, and at once raises the question whether it is worth while. What sort of an idea, for example, of the anatomy of the brain can be conveyed in six pages. A little knowledge is, no doubt, here as elsewhere, a dangerous thing, and certainly if such knowledge goes no further, must be of little value to the student. The second volume, dealing with more practical details, is much more to be commended.

The criticism suggested above is by no means peculiar to these volumes, but seems to us inherent in the whole system of training for nurses, as now generally adopted at our larger hospitals.

Simon's Clinical Diagnosis. A Manual of Clinical Diagnosis by Microscopical and Chemical Methods. For Students, Hospital Physicians and Practitioners. By CHARLES E. SIMON, M.D., late Assistant Resident Physician, Johns Hopkins Hospital, Baltimore. New second edition, revised and enlarged. In one octavo volume of 530 pages, with 135 engravings and 14 full-page colored plates. Philadelphia and New York: Lea Brothers & Co. 1897.

The second edition follows the first at the end of the year. This exhibits not only the demand for a book of this character, but also the rapid changes in methods of work and enlargement of knowledge in regard to the subjects of which it treats. This is from one point of view encouraging, and from another discouraging. The size of the volume has been increased by fifty pages, new methods of chemical examination have been given and some of the older ones have been omitted.

The chapter devoted to the examination of the cerebro-spinal fluid, which consisted of a few lines only in the first edition, now occupies several pages. The parasitology and bacteriology of the blood and of many of the secretions have been almost entirely rewritten. We do not doubt that a year hence in another edition as great and as numerous changes would be required.

A Hand-Book of Midwifery. By W. R. DAKIN, M.D., Obstetric Physician and Lecturer on Midwifery and Diseases of Women to St. George's Hospital; Physician to the General Lying-in-Hospital; Late Examiner in Midwifery and Diseases of Women on the Conjoint Board of the Royal Colleges of Physicians and Surgeons in England. Pp. 629, 400 illustrations. London, New York and Bombay: Longmans, Green & Co. 1897.

One is impressed with the large amount of well arranged information contained within the covers of this book. The illustrations are numerous, and for the most part small original diagrams, free from unnecessary details. As in most English books, the operations are described with the patient lying on the side, so that the text and diagrams are confusing to the American student. Hegar's sign seems to be mentioned by name in the index only. The important matter of prophylaxis and treatment of septicemia is rather inadequate. It is to be noted that the author prefers the finger to the curette for cleaning the septic uterus, and in fact mentions the latter instrument only in a note. Iodoform and gauze drainage are not mentioned at all. One naturally turns with interest to the articles on Eclampsia and Placenta Previa. In both early delivery by dilatation and version are recommended. For dilatation of the os the author prefers the Champetier de Ribes's bag to the fingers.

The index of 40 pages is very satisfactory.

THE present epidemic of typhoid fever at King's Lynn and the investigation of its water-supply, recall the fact that in 1423 the lack of drinking-water caused such distress that Henry VI gave powers to cut a canal to Gayton River, the water of which was considered to be very pure. Under Cromwell the water-canal was carefully cleaned out and a larger supply provided for. Strange to say, the keepers of ale-houses alone were made to pay for this improved water-supply.

THE RELATIVE SAFETY OF CHLOROFORM AND ETHER.

A NEW method for testing the efficiency of anesthetics has been claimed by Dr. Augustus Waller, President of the Section of Anatomy and Physiology at the recent meeting of the British Medical Association at Montreal, and was explained by him in an extremely interesting and important paper published in the *British Medical Journal* of November 20th.

The method in brief consists in subjecting freshly prepared nerves, while under the influence of the vapors of the anesthetics, to electrical stimulation, and studying their reactions. He found that anesthesia of the nerve was produced by various anesthetics, ether, chloroform, bromide of ethyl, etc., so that while the nerve was subjected to the vapors, the galvanometer failed to indicate response to electrical stimulation.

If the vapor is removed, the nerve recovers itself, and the response to stimulation again appears. In testing the various vapors, Waller found that exposure to any of them if sufficiently long continued produced the death of the nerve, so that it no longer after the removal of the vapor responded to stimulation.

As a result of his experiments, Waller found that chloroform, as compared with ether, was seven times more deadly when tried upon the isolated nerve, in other words, that in the case of ether there was a seven times greater margin between the lethal and non-lethal doses than in that of chloroform.

Nitrous oxide, according to Dr. Waller, is an anesthetic which has little or no action on nervous tissue. Carbonic dioxide, which Snow and Richardson lauded as an anesthetic, is, Dr. Waller finds, a powerful agent to produce "immobilization," thus confirming the assumption of the older observers. But a fact of extreme interest, because, unless carefully explained, liable to fatal misunderstanding, is Dr. Waller's observation that the presence of carbonic dioxide favors anesthesia and lessens its risk. The combination of chloroform and carbonic oxide is not, it must be distinctly understood, simply chloroform given with

very little air. This distinction is made very plain by Dr. Waller himself.

By Dr. Waller's simple and beautiful methods we are set in a measure free from the necessity of settling the complicated question upon which previous experimenters have been divided as to whether chloroform killed by paralyzing the respiration through the nervous system, or by producing circulatory failure by direct action upon the heart or indirect action through the vaso-motor system. If chloroform actually attacks nervous tissue and destroys its irritability, and its action in this respect is seven times more powerful than that of ether, without going into the exact mechanism by which it produces death we are furnished with an excellent reason for the fact that in the statistics of deaths under the two anesthetics ether stands better than chloroform.

The actual proportion in its favor is about thirteen to one, but, as Dr. Waller has pointed out, the action of anesthetics on the whole organism, though exemplified simply and forcibly by their action on nerve tissue, is far more complex.

"From a practical point of view," writes Dr. Waller, "from the most immediately practical point of view possible, that of the man in the street, who if he has to submit to an operation wishes to take least risk, the question is more elementary. He desires to be most safely anesthetised by any drug, not necessarily by chloroform, and would probably express a somewhat emphatic indifference as to whether, if he is killed, his death is to be by the lungs or by the heart."

The "chloroform dilemma," with which Dr. Waller concludes his paper must prove a difficult one for those to dispose of who administer chloroform as a routine anesthetic for all surgical procedures.

"With reference" he says, "to the admittedly large number of deaths by chloroform, there seems to me to be no escape from the two horns of a dilemma. Such deaths are the result (a) of an agent dangerous under all circumstances, or (b) of an agent dangerous only when unskillfully administered.

"(a) If chloroform is dangerous under all circumstances, it may not be employed in minor surgery. Death in this class of cases is therefore unjustifiable, and should be considered as a criminal offence.

"(b) If chloroform is dangerous only when unskillfully administered, then, again, death by chloroform is unjustifiable, and ought to be considered as a criminal offence.

"There can be no escape from one or other of these two alternatives. There have been deaths due to careless or to unskilled administration; there have also been deaths in skilled and careful hands. But unless we are to admit that chloroform is a 'safe' anesthetic, and any death the result of carelessness or ignorance, we must admit that chloroform, being a potent reagent, is, *ipso facto*, a 'dangerous' reagent, to be used only on serious grounds, and not to be employed as a routine drug in all kinds of cases, simply on account of its superior convenience."

THE TWENTY-EIGHTH ANNUAL REPORT OF THE MASSACHUSETTS STATE BOARD OF HEALTH.¹

THE general report of the Board includes a condensed statement of the work done under the statutes defining the duties of the Board, to which is appended a statement in brief of a sanitary survey of the sewerage question of Salem and Peabody, of a plan for the improvement of the Neponset Valley and of the joint report of the Board with the Metropolitan Park Commission on the improvement of the Charles River.

The second part of the report contains the fuller details of the work of the Board under the acts relating to water-supply and sewerage, food and drug inspection, reporting of infectious diseases, and special papers on a comparative study of the toxin production of diphtheria bacilli, on the production and use of antitoxin, on diphtheria cultures, on the diagnosis of malaria, on examinations for tuberculosis, on a forty-years' summary of the vital statistics of the State, and finally, statistical summaries of disease and mortality, and the usual notes on the health of towns. An admirable index adds to the value and completeness of the report.

Five cases of small-pox were reported in the State; and, under the provisions of the interstate agreement, thirty other cases were reported from the other States and Canada. Notice was also received of three steamers' arrivals in New York, with cases of small-pox on board among the immigrants.

Several investigations were made of limited outbreaks of typhoid fever, and advice was given suitable to each case. The gratifying decrease in the mortality from this disease continues, and the careful analysis of its comparative prevalence and fatality in the cities of the State for the last twenty-five years furnishes many hints for its further control.

In order to restrict the prevalence of diphtheria, a system of examination of throat cultures has been established, whereby such cultures may be forwarded to the Board for examination from any city or town in the State; and antitoxin is furnished as required.

The investigations with regard to the prevalence of malaria have been continued, especially in the Charles River Valley; and three serious outbreaks of the disease in Uxbridge, North Saugus and Woburn were made the subjects of special inquiry.

In consequence of the more efficient organization of the local Boards of Health no complaints were made to the State Board during the year with regard to offensive trades.

A new edition of the Manual of the Health Laws has been prepared, an indispensable aid to local health boards, physicians and court officers.

A few towns have reported the extensive prevalence of poisoning from lead service-pipes; and in others cases have occurred, as a result of which the Board is investigating the subject of the action of lead pipes on water-supplies in all its bearings.

¹ Public Document, No. 34. Twenty-eighth Report of the State Board of Health of Massachusetts. Boston: Wright & Potter Printing Co., State Printers, 18 Post Office Square. 1897.

One hundred and thirty summer resorts were inspected during the year as regards their sanitary condition. Notice was sent where the existing conditions were found unsatisfactory, and the aid of the Board was offered in examining and approving satisfactory plans for remedying evils.

The relation of the State Board to local boards has become much closer, especially since the quarterly meetings for discussing together matters of interest to the public health; and an evident improvement in the sanitary condition of the several towns is an evident result. Among the duties imposed upon local boards in more recent years are those which relate to cattle diseases, the inspection of plumbing, the licensing of stables, the inspection of bakeries, the reporting of cases of infectious diseases and of annual mortality returns to the State Board of Health. And to these duties will doubtless soon be added inspection of dairies.

Of the population of the State, 89.8 per cent. has public water-supplies. In 11 cities and towns, with an aggregate population of 98,287, and in several large public institutions purification of the sewage is effected by filtration. The Board gave advice on questions of water-supply, sewerage, and sewage-disposal during the year, in 42 cases; and the consideration of these important subjects occupies nearly 600 pages of the Board's report, closely packed with useful information.

During the year 8,357 samples of drugs and food, including milk, were examined by the Board's chemists.

The special topics of report on malaria, tuberculosis and diphtheria from the laboratory of the Board indicate a beginning of investigations of the greatest scientific interest and practical value.

The forty years' summary of the vital statistics of the State, a model report, by the Secretary of the Board, has already been discussed in the JOURNAL.² In saying that this twenty-eighth report of the Board is fully up to the standard of its predecessors we give it the greatest praise.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE UNITED STATES NAVY.

THE annual report of the Surgeon-General of the Navy for the year 1897 contains many interesting features. From the report of the Bureau of Medicine and Surgery we learn that all the naval hospitals have been fitted up with modern aseptic operating-rooms and bacteriological and chemical laboratories, thus greatly increasing their efficiency.

During the year ending June 30, 1897, thirty-six candidates appeared before the examining boards of the navy, only eight of whom were successful in passing the examination. Within the past year the number of vacancies has increased, there being at present fifteen vacancies to be filled, with no immediate prospect that a sufficient number of satisfactory candidates will present themselves. "Legislation toward the improvement of the present status of assistant surgeons

in the navy, and placing them on a similar footing with assistant surgeons in the army is urgently needed, and a bill having this object in view will be submitted to the Department at an early date, with the recommendation that it be transmitted to Congress with a favorable endorsement."

It is the intention of the bureau to provide facilities for the use of x-rays in the principal naval hospitals.

The health record of the Naval and Marine Corps for the calendar year 1896 was very satisfactory. There was a considerable decrease in the rate of admission to the hospitals and a marked diminution in the number of deaths, although the numerical strength of the force has increased 7.62 per cent. There were 78 deaths during the year (64 from disease and 14 from injury). In the previous year, with a smaller force, there were 90 deaths.

Malarial diseases head the sick list of the year, with 850 cases. There were 593 cases of wounds, 586 of rheumatic affections, 468 of diarrheal affections, 400 of epidemic catarrh, 201 of alcoholism, 66 of pneumonia, 59 of heat stroke, 56 of typhoid fever, 48 of pneumonic tuberculosis, 31 of mumps, 16 of nephritis, 15 of measles, 14 of organic heart disease, 11 of erysipelas, 5 each of cholera and small-pox, 4 of scarlet fever and 2 of varicella.

Of the 59 cases of heat stroke, 40 were caused by heat in the fire- and engine-rooms.

The five cases of cholera all occurred on the *Boston*, the first case appearing while she was stationed at Shanghai, on August 20th, in a man who had been allowed shore liberty.

Five cases of small-pox occurred during the year, and there were eight deaths from drowning.

Among the special cases of interest occurring on board ship was that of two apprentice boys who contracted syphilis from the process of tattooing their left forearms. These cases are reported by Passed Assistant Surgeon G. B. Wilson, as occurring in the gunboat *Castine* while at Buenos Ayres in July.

A case of successful operation for penetrating wound of the abdominal cavity with protrusion of omentum is reported by G. Tucker Smith, Passed Assistant Surgeon, U. S. S. *Adams*. Remittent fever occurred on board vessels stationed at Woosung, China, and at Key West.

Full statistical tables are given of the data upon which the report is based, and full reports of the surgeons in charge of the naval hospitals and in medical charge on board ship.

A full and interesting report on "Cholera in Japan and Plague in China," by W. F. Arnold, Passed Assistant Surgeon, is a feature of the report, as is also an article on "The Practical Disinfection of Ships of War," by Thomas C. Craig, Surgeon, retired.

The general principles applying to the disinfection of ships, and the special measures to be taken in case of special infective diseases, such as cholera, typhoid, etc., are discussed in this last article, which is of special interest and value.

² Vol. cxxxvii, p. 606.

THE NOTIFICATION OF MEASLES.

THERE appears to be a divided opinion in England as to the utility of considering measles as a notifiable disease. Dr. H. Kenwood, Medical-officer of Health of Stoke Newington, presented the subject in a paper before the Sanitary Institute (April 7, 1897),¹ in which he opposed the notification of measles. His chief reasons for this ground of belief lay in the rapidity of the spread of the disease, the notification coming too late to be of use, and the difficulty of diagnosis at the onset of illness, all those who are susceptible having been fully exposed to infection during the exceedingly infectious pre-eruptive stage of the disease. In summing up the results, he says:

The conclusion to which I am driven is that it may be useful to bring measles under the Notification Act in rural districts and in small, isolated communities, if in these cases every advantage is taken of the information thus obtained, if efforts also be made to detect unnotified cases and the means of hospital isolation be provided; but, in large communities, especially when not adopted in neighboring districts, the measure is not to be recommended in the absence of sufficient isolation provision, a large permanent staff and the adoption of other means than "notification" of bringing the existence of cases to the knowledge of the sanitary authority. In short, if it were possible, in urban districts, to deal with every case notified with the same care and thoroughness as in a case of small-pox, it might prove of value, but certainly not without.

The best remedy lies not in notification, but in the education of the masses, and in the taking of certain precautions against school infection.

Efforts hitherto made in this direction are of two classes: the distribution of handbills or booklets, which are seldom read; or free lectures, which are seldom attended except by those who least require them. We must begin at the beginning and educate in childhood. The State must deal with the individual while he is still under the control of its compulsory education, while the simple and priceless knowledge of the laws of health and disease prevention may be taught and instilled into plastic minds.

The active co-operation of school authorities is necessary, since infectious diseases spread largely through the schools. Scholars in each school should be subject to frequent medical inspection, and this inspection should be made with much greater frequency during epidemic prevalence. A scheme which fully takes advantage of all the means which schools offer, of (a) educating the future parents, and (b) of gaining early information and checking the spread of infection, appears to me as likely to offer a surer means of reducing measles mortality and at considerably less trouble and cost than any scheme involving "notification."

With this paper Dr. Kenwood presents a list of the districts in England, 77 in number, in which measles was compulsorily notifiable before March, 1892. During the succeeding five years, to March, 1897, the notification had been revoked in 32, or two-fifths of the number, and in the remaining 45 there were very few which presented satisfactory results. In the discussion which followed the disputants *pro* and *con* were in nearly equal numbers.

The significance of the foregoing extract will be better understood by brief reference to the Notification Act of England, which became a law in 1889. By the terms of this Act the notification of infectious diseases to the sanitary authority was made compulsory throughout London, while the principle of local option was applied to all other districts. Great opposition

was at first made by the medical profession, but the fallacy of these objections has been abundantly proven by seven years' experience. The notification is made upon a certificate furnished by the physician, for which a fee of two shillings and sixpence is paid, except in the case where the certifier is the medical officer of a public institution, when the fee is one shilling. The diseases to which the Act applies are small-pox, cholera, diphtheria and membranous croup, erysipelas, scarlet-fever, typhus, typhoid fever, puerperal fever, and any other infectious disease which may be added at the option of the district. In some instances measles, hydrophobia and chicken-pox have been added. The Act is now in force in districts containing about 90 per cent. of the population.

In the United States some form of notification is in force in most of the cities and large towns and in some entire States.

MEDICAL NOTES.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the two weeks ending at noon, December 22, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 92, scarlatina 51, measles 24, typhoid fever 12.

DIPHTHERIA IN BOSTON, MARKED DECREASE OF MORTALITY. — The last weekly statement of the city's health tabulated at the office of the Board of Health shows not merely a decrease of the death-rate over the corresponding week of last year, but a decrease of 50 per cent. on deaths from diphtheria for the same corresponding period.

THE SUMMER HOSPITAL AT RAINSFORD ISLAND. — In the second annual report of the medical director of the Summer Hospital on Rainsford Island a marked improvement is shown over the record of the first year, both as regards the number of patients admitted and in the decrease of mortality. The yearly expenses have been reduced greatly by the combining with the hospital the training school for nurses, whose services are paid chiefly by the instruction they receive. The hospital was opened to receive cases on June 11th, and was closed on September 30th. During that time 124 babies under two and one-half years of age were admitted. Of these 35 died, which, in consideration of the serious condition of many at entrance, is regarded as a low percentage.

TREFFLÉ GARCEAU, M.D. — Dr. Trefflé Garceau, one of the best-known physicians of the Roxbury district, died suddenly at his home, No. 22 Highland Street, December 19th, of myocarditis. He was born in Montreal sixty years ago. He obtained his early education in the schools of that city, and then entered St. Mary's College, from which he was graduated with high honors. He entered the College of Physi-

¹ Journal of the Sanitary Institute, July, 1897, p. 161.

cians and Surgeons in Montreal, and was graduated in 1863. He came to the United States and settled in Lowell, where he practised two years. About 1866 he came to Boston and began practice in Roxbury, where he has ever since had an extensive practice. He was a member of the Massachusetts Medical Society, Roxbury Medical Club, and was one of the prominent members of the French Catholic Church, on Isabella Street. Fifteen or twenty years ago he was a member of the school committee. He leaves three sons, one of whom, Edgar Garceau, M.D., was associated with him in his practice.

ANNUAL REPORT OF THE LYNN HOSPITAL. — The annual report of the Lynn Hospital for the year ending December 1, 1897, shows that during that time 800 patients were treated in that institution. The average daily number under treatment was 35. The whole number of out-patients treated was 8,000, and the whole number of new out-patients treated was 3,000. The number of deaths during the year was 81; of these 26 died within thirty-six hours after entering the institution. There were 321 operations performed with the patients under the influence of ether, and 51 of these were cases of abdominal section. There were 19 cases of appendicitis. There were 40 cases in the confinement ward and 42 births. The training-school now has 14 nurses and two head nurses, which gives the hospital 16 nurses, with the matron. It is the wish of the superintendent that the district nursing done in co-operation with the Associated Charities should be continued.

NEW YORK.

CHARITABLE INSTITUTIONS AND THE PUBLIC FUNDS. — At the meeting of the Board of Estimate on December 15th the claims of the charitable institutions for public funds which were not provided for the previous week, when the Medical League protested against the giving of money to hospitals connected with medical schools, were again considered. The appropriations asked for the Post-Graduate School, the Polyclinic, and Homeopathic School hospitals were not passed, as the vote on the matter resulted in a tie, one of the five members of the Board being absent. The sum of \$127,500 was voted for an addition to Bellevue Hospital and for buildings on Ward and Blackwell's Islands.

POLICE SURGEONS APPOINTED UNDER CIVIL-SERVICE RULES. — On December 17th Drs. Arthur S. Vosburgh and John J. Quigley were appointed police surgeons, to fill two vacancies on the board, they being the highest, by examination, on the eligible list of the civil service. The salary of the position is \$3,000 per annum.

THE HEALTH OF NEW YORK CITY. — In his report on the health of the city during the eleven months ending November 30th, referred to in last week's JOURNAL, Dr. Tracy, Register of Records, points out that not only has the death-rate been excep-

tionally low, but the actual number of deaths, notwithstanding the great increase in population, has been smaller than in the same period of any other year since 1886. The very marked decrease, from 1896, of 726 in the deaths from snstroke is explained by the cool summer of 1897. The other marked decreases are in diphtheria, croup, measles, diarrheal diseases, Bright's disease, pulmonary tuberculosis and pneumonia. With the exception of scarlet fever, all the causes of death which show an increase belong to classes of affections which are not regarded as amenable to sanitary regulation. Dr. Tracy believes that the decrease in the death-rate can be accounted for, at least in part, by such improvements in the methods of sanitary administration as the use of anti-toxin in the treatment and prophylaxis of diphtheria, the permit system for regulating the sale of milk, the treatment of consumption as an infectious disease, the medical supervision of schools, and the recent cleanliness of the streets. The influence of all these factors, he also thinks, is to be felt even more strongly hereafter. In conclusion, he says it should be stated that the deaths of children under five years of age, an acknowledged test of the sanitary condition of a community, have numbered only 14,301, as against 15,907 in 1896. This represents only 39.9 per cent. of the total deaths, and a child death-rate of only 68.9 per thousand living children of that age, as against 78.9 for the corresponding months of last year.

Miscellany.

BRAIN DESUETUDE.¹

SPEAKING at Selkirk on the 8th instant, Sir James Crichton-Browne dwelt on the dangers to health involved in indolence and disuse of the brain. The medical profession, he said, adapting itself to the needs of the times, had felt it incumbent upon it during the last decade to insist mainly on the evils of misuse of the brain, on the excessive strain not seldom imposed on it in these days in the fierce struggle of the race to be rich, and more especially on the overpressure imposed on it in the name of education when in an immature state; but they were not less keenly alive to the correlative evils of the disuse of the brain. Elderly persons who gave up business and professional men who laid aside their avocations without having other interests or pursuits to which to turn were in many cases plunged in despondency or hurried into premature dotage. He did not know any surer way of inducing premature mental decay than for a man of active habits to retire and do nothing when just past the zenith of life, and, on the other hand, he did not know any surer way of enjoying a green old age than to keep on working at something till the close. It had been said that one of the rewards of philosophy was length of days, and a striking list might be presented of men distinguished for their intellectual labors which they had never laid aside, who had far exceeded the allotted span of human life. Galileo

¹ The Lancet.

lived to seventy-eight, Newton to eighty-five, Franklin to eighty-five, Buffon to eighty, Faraday to seventy-six, and Brewster to eighty-four years. Sir James Crichton-Browne drew special attention to the great age generally attained by English judges. They were, he said, men who could never fall into routine, but were called upon, as long as they held office, for mental effort in considering and deciding on the new points and cases which were constantly submitted to them. For the most part, they had at one period of their lives undergone some overstrain in the active practice of an exacting profession, and yet they lived to a ripe old age, and were, he believed— notwithstanding the jokes and jibes of hungry aspirants at the bar—more exempt from dotage than any other class of the community. The sustained brain-friction in their case kept that organ bright and polished.

These facts, he thought, ought to inspire us with some doubt as to the wisdom of the compulsory retirement and pension *régime* under which we lived. He had known several cases of mental disease induced solely by enforced idleness in men turned out of the public service, and more particularly the army, in conformity with a fixed rule, while still in the prime of life and capable of useful work. On entering the public service a man had to ascend by graduated steps of increasing work and responsibility. Was it not possible to arrange graduated steps of diminishing work and responsibility by which he might descend on leaving it? Much waste and wretchedness might thus be saved. The physiological notion of life was not cruel overpressure at the beginning, penal servitude in the middle, and silly superannuation at the end, but the timely, continuous, orderly, well-balanced exercise of all the functions and faculties with which the being is endowed.

ABUSES OF MEDICAL CHARITY.

RESOLUTIONS ADOPTED BY THE BOSTON MEDICAL SOCIETY, DECEMBER 18, 1897.

Whereas, the unrestricted abuse of Medical Charity in the large hospitals and dispensaries of Boston is being seriously complained of by a large number of general practitioners, and

Whereas, the State has granted charters to hospitals and dispensaries for the definite purpose of giving medical and surgical care and treatment to indigent persons within this city and the Commonwealth, and

Whereas, the Boston Medical Society, individually and collectively, recognize, with every feeling of sympathy, the rights and the just claims of some of our citizens to the benefits of public and private charity, and will not be found wanting in generosity in whatever may tend to foster the moral, social and physical well-being of the sick, the poor, the destitute, the lowly, the worthy and the unfortunate, and

Whereas, large numbers of persons, of both sexes, frequently, daily and repeatedly receive medical and surgical advice and treatment gratuitously, for numerous cases of minor surgery and ordinary illness, who are believed to be financially competent to pay moderate fees, and

Whereas, the time, facilities and attention at the dispensaries being necessarily limited, that which is received by the well-to-do and the undeserving is, in that proportion, withheld from those who, by the chartered rules of those institutions, are justly entitled to their benefits, and

Whereas, the practitioners of medicine and surgery of any community who have duly graduated from accredited medical colleges and have incurred the expense of locating in such communities naturally and justly feel that their

present and prospective rights and privileges are wrongly encroached upon by the abuses now in practice in connection with medical charities;

Therefore, *Resolved*, that it is the opinion of this Society that some means can be found to check or modify this formidable evil, and

Resolved, that an urgent call be made upon all members of the profession who are in sympathy with this movement and have at heart the best interests of the profession to render such moral assistance and financial support in the adoption of such measures as will tend to eradicate and prevent these evils, abuses and practices, and

Resolved, that an open meeting be held in the near future and the profession at large be invited to be present, and

Resolved, that a copy of these resolutions be sent to the *Boston Medical and Surgical Journal*, *Journal of the American Medical Association*, *Medical Record*, *New York Medical Journal* and *Medical News*, for publication.

For the Society,

M. GERSTEIN, M.D., *Secretary*,
1038 Washington Street.

Correspondence.

[Special Correspondence.]

BERLIN LETTER.

INCREASE OF TETANY IN BERLIN.—GERMAN INTEREST IN THE DISEASE.—THE PUPILS IN HYSTERIA AND EPILEPSY.—PROFESSOR MUNK'S STARTLING CONCLUSIONS AS TO THE THYROID NOT BEING ESSENTIAL TO LIFE OR HEALTH.—MOMMEN'S EIGHTIETH BIRTHDAY AND GERMAN SEPTUAGENARIAN SAVANTS.

BERLIN, November 26, 1897.

MR. EDITOR:—Professor Heubner showed, in his children's clinic at the Charité last week, some cases of tetany in very young children. During the course of his remarks on the disease, he stated his conviction that it was on the increase here in Berlin. This would not seem to be the result merely of more careful methods of diagnosis, but to represent an actual invasion of the disease. This increase has been noted not alone in Professor Heubner's clinic, but in other clinics for children.

It is to be hoped that its present occurrence at Berlin may prove the source of some more definite information with regard to this as yet rather mysterious disease. Its peculiarity of geographical distribution has always been one of the special mysteries. Though first studied at Paris in the early '30's, where a good many cases of it were observed, its frequency has greatly decreased there and cases are exhibited as rarities. Vienna has always been especially the favorite home of the disease, but it has been even more frequently observed of late years than formerly. Berlin practically has had no cases of the disease until now. Eichhorst, in his long years of service here in Frerich's clinic, never saw a case.

At Prague it is so common that it constitutes over one per cent. of all the diseases treated in Escherich's clinic; in children under three years of age, about one-half per cent. of all the diseases treated in the University Clinics there. Professor Escherich, who is one of the acknowledged authorities on children's diseases in Europe at present, has considered it of sufficient importance to make it the subject of a special communication to each of the last three International Medical Congresses.

The accepted theory of its etiology now seems to be its ascription to toxins. These are usually considered to be the result of faulty or incomplete digestion with consequent absorption of unsuitable digestive products. That certain bacterial products are pathogenic of the disease too is admitted, and even the existence of a specific bacillus is maintained, though not by many. Difference in foods in various places has been suggested as the cause of its peculiar geographical distribution, while variations in the

form of popular food-stuffs at different times is thought to account to some extent for the changes in its curve of frequency of occurrence at different periods. Generally, however, there is a vein of distrust of former examinations running through the present literature of the subject that would seem to indicate that exacter methods of diagnosis have led in some cases to the seeming increase in frequency of the disease. One is tempted to wonder if the employment of these methods in America, where only some 70 cases (I believe) of tetany altogether have been reported, would not lead to the discovery of the latent forms that have occupied so much attention here of late.

As Escherich and Heubner both point out, one of the suspicious symptoms that have led them to look for and find other confirmatory signs are laryngospastic attacks —, and these are frequent enough in America. If, in addition to some such unexplained spastic condition as this, Trousseau's symptom can be developed with the facialis phenomenon (Chvostek's sign) and exaltation of the mechanical and electrical excitability of the muscles, then the diagnosis of tetany is justified even though no generalized spasms occur. Von Jaksch and Frankl and Hochwart, the most recent writers on tetany, and who have each been very favorably situated (Prague and Vienna) for seeing a number of cases of the disease, consider that, with the symptoms described present, not even the spasms of hands and feet that used to be called carpopedal spasm are necessary for the justification of the diagnosis. Some years ago this slight form was itself scarcely considered to justify the diagnosis tetany.

The question of the differentiation of cases of hysteria from true epilepsy when the attacks take on the form of hysterio-epilepsy would seem to be growing more rather than less difficult, as observers investigate supposedly differential symptoms more carefully. The reversal of the formulæ of the alkaline and earthy phosphates pointed out by Gilles de la Tourette and Cathelineau as distinctive of hysteria is too difficult of determination for practical purposes, is surrounded by too many modifying circumstances that limit its value and besides has not been confirmed by all observers. In consequence one hears scarcely anything of it here in Germany.

Some recent work of Dr. Westphal in Professor Jolly's clinic at the Charité would seem to destroy the value of almost the only other differential diagnostic sign that was left, the failure of the pupils to react to light in true epileptic attacks. Scattered cases of hysteria with loss of pupillary light-reflex have been reported occasionally in the literature, but have been considered as instances of faulty observation as a rule. When Karplus, from Krafft-Ebing's clinic, reported some cases last year of *pupillenstarre* in hysteria, he called attention to the general feeling of incredulity with regard to such cases, and now Dr. Westphal does the same. Both are, however, thoroughly competent observers, so that the loss of pupillary reflex to light can no longer be considered pathognomonic of epilepsy.

Professor Munk's article on "The Physiology of the Thyroid," in the last number of *Virchow's Archiv*, is rather startling in its conclusions. He absolutely denies that the thyroid is essential to animal life, or that its removal leads to myxedema in animals, or that when it is removed its influence may be supplied by implantation or ingestion of the thyroids of other animals. In other words, there is an official contradiction from the department of physiology of the University of Berlin of all the present prevailing opinions as to the physiology of the thyroid.

As only articles of whose scientific value there can be no doubt find their way into *Virchow's Archiv*, and the editor prides himself on the personal supervision of the material that appears in the *Archiv*, the present article represents in a way the school of scientific medical thought in Germany. The experiments were too carefully done to admit of cavil as to the results, and there are too many of them for a series of coincidences to have had a disturbing influence on the conclusions they suggest. The opinion is

openly expressed from many quarters now, that, after serving as the basis for therapeutic measures which are undoubtedly efficient, and having led to a set of conclusions as to the importance of the thyroid in man which can scarcely be questioned in the light of therapeutic results, the conclusions drawn from the removal of animal thyroids are now to be materially modified, at least as regards the animals.

Professor Mommsen, the famous historian of ancient Rome, will celebrate his eightieth birthday next week, but he has absolutely refused to allow of any public felicitations on the occasion. Addresses are to be sent him by the various faculties, however, and due honor will be shown to the man of whom all think so much. He is still doing some University work and like Virchow, who celebrated his seventy-sixth birthday a month ago and his fiftieth anniversary as a teacher at the University of Berlin a few days ago, he insists on remaining in harness. Like so many of the German savants who at seventy and over are still vigorous intellectually and still able to do good work, he is a living proof that intellectual work, even when intense, persistent and absorbing for a lifetime, does not wear out the human machine before its time.

It is worry, not work, that causes serious friction. Mommsen's absorption in his work has for years been so great that the stories of his abstractedness are many. His failure to move from his place in the Vatican Library where he was at work, though the Pope and his suite were passing through; his failure to recognize his best friends at times when he met them — once even one of his own children, it is said — show how thoroughly all his mental attention was centred around the great subjects that occupied him continually. At eighty, however, he is still hale and hearty and planning new work. It reminds one of Ranke beginning at ninety years of age a Universal History to fill twelve volumes, of which one volume a year was to appear. The ordinary impression, so universally prevalent that intellectual work is especially wearing, could not receive a more striking contradiction.

BILLROTH AND PIROGOFF.

BOSTON, December 15, 1897.

MR. EDITOR: — In connection with the editorial on N. I. Pirogoff, which appeared in the *JOURNAL* of December 9th, the following facts, as related by a certain Dr. Wilhelm von Vragassy (*vide Deutsche Revue* for November, 1897), may be of interest to your readers.

It appears that the famous surgeon Theodor Billroth (1829-1894), a statue of whom was recently erected in one of the lecture halls of the medical department of the University at Vienna, where he occupied the chair of surgery, entertained the highest respect for Pirogoff. On the back of his (Billroth's) picture presented to Pirogoff during the latter's visit to Vienna, there is the following autographic inscription: "Dem verehrten Meister Nicholas Pirogoff. Wahrheit und Klarheit im Denken und Empfinden, wie in Wort und That, sind die Sprossen auf der Leiter, welche die Menschen zum Sitze der Götter führt. Ihrem ebenso kühnen als sicheren Führen auf diesen nicht gefahrlosen Wege nachzufolgen soll stets mein eifriges Bestreben sein. Ihr aufrichtiger Bewunderer und Freund — Billroth." This respect was evidently reciprocated.

Some two years before Pirogoff's death his wife observed that he rinsed his mouth rather too frequently, not only after meals, but also at other times. To her somewhat anxious inquiries as to the cause of such a procedure Pirogoff, who was an inveterate smoker, replied that by that means he hoped to protect the mouth from the possible injurious effects from excessive smoking. While once thus rinsing his mouth with too hot water, he scalded it, and on examining it, his wife detected a little swelling, of a somewhat

painful nature, on the hard palate near the alveolar border. As it increased in size and became more painful, there arose a suspicion in Pirogoff's mind that it might be a malignant neoplasm, but his anxiety was somewhat allayed by Dr. (now Professor) Sklifosovski, who diagnosed it—at least he told Pirogoff so—as an incurable fistula, but by no means of a malignant nature. However, the rumors gained ground among the profession that Pirogoff was suffering from a carcinomatous growth, and he was urged by many of the most prominent Russian surgeons to subject himself to an operation. But so great was his faith in Billroth, that he left for Vienna to seek his advice in the matter. Contrary to all expectations, Billroth made light of the diagnosis of the Russian surgeons, and not only advised against any operative interference, but stoutly denied the malignancy of the growth in his answers to anxious inquiries from a great many prominent persons in Russia concerning Pirogoff's health. Reassured, Pirogoff returned to Russia, where he died a few months later of a cancer of the superior maxillary bone.

The occurrence naturally raised a storm of indignation and abuse in the press and the profession, but the great German surgeon explained his position in the affair which makes it appear in a different light. In a letter to a Russian surgeon he declares, that notwithstanding the fact that the diagnosis of carcinoma was but too evident, and also substantiated by microscopical examination, he could not but advise against operating on a man, who was on the wrong side of seventy, presenting marked symptoms of senile marasmus, with indications of approaching double cataract. Even if he were to stand the operation (which was hardly possible), a recurrence of the growth was sure to take place. "Let me assure you that I would hesitate to perform such an operation on a patient twenty years younger and of a more robust constitution; because my thirty years' experience as a surgeon has taught me that carcinomatous and sarcomatous tumors arising from the posterior part of the superior maxilla can never be removed thoroughly, even in cases where we are sure that the patient will bear the operation well. A total extirpation of such a tumor by the aid of the knife is impossible in this place, partly because of the anatomy of the part, partly because of the technical difficulties, unless we expect growths enclosed in a sac. I am no longer that bold operator whom you knew years ago in Zürich. Before deciding on the necessity for an operation, I always propose to myself this question, Would you permit such an operation as you intend performing on your patient to be done on yourself? Years and experience bring in their train a certain degree of hesitancy (Zurückhaltung). Every year brings out clearer and clearer the shortcomings of our art."

Very truly yours,
A. ROVINSKY, M.D.

WINTER PARK, FLORIDA, AS A WINTER RESORT.

ANDOVER, MASS., December 15, 1897.

MR. EDITOR:—As the cold weather of winter approaches, many invalids and semi-invalids, who realize that they can obtain increased length of days, complete or partial renewal of health and strength with greater comfort, by fleeing from the rigors of our northern season to a softer and more congenial climate, are doubtless discussing the important question of a suitable location. In behalf of these valetudinarians, I believe that I am doing a positive service in directing the attention of physicians who may not be familiar with the locality to Winter Park, Florida, a resort which possesses some advantages not to be found in many better known and more frequented places.

Centrally located on high land, on the "backbone" of the State, away from the windy coast, it has a dry and porous soil and is free from the malarial dangers of the swampy districts. The surface of the country is pleas-

antly diversified by pine groves, by handsome orchards of orange trees with their deep green foliage and golden fruit, now just beginning to bear after the set-back by the frost of three years ago, and by many small but delightful fresh-water lakes. The climate during the winter months is very agreeable, with a large preponderance of clear days, varied by occasional refreshing showers. The temperature from the first of January until the middle of March is very equable, ranging from 60° to 85° F., and the warmer days are tempered by cooling breezes impregnated with the balsamic odor of the pine forests.

Winter Park, in my opinion, is one of the most inviting places in the Southern States for a winter home for those who seek rest and comparative quiet, with pleasant and rational society.

I will add that there is a fine hotel, "The Seminole," at Winter Park, which furnishes an excellent *cuisine* and other attractions at reasonable rates for those who desire hotel life, while for those who may prefer them, furnished cottages afford the opportunity for more private family life. The best evidence of the excellence of this resort is found in the considerable number of those whose annual pilgrimage thither attests their satisfaction and the benefit which they have received. Having learned by observation and personal experience of the merits of Winter Park, I feel justified in recommending it to the profession as worthy of consideration as a winter home for those who are not too far advanced in invalidism, but who wish to avoid our inclement New England winters and are able to make the journey in safety.

Very truly yours,
C. N. CHAMBERLAIN, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, DECEMBER 11, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 11, 1897, TO DECEMBER 17, 1897.

Leave of absence for one month, to take effect about December 15, 1897, with permission to apply to the Adjutant-General of the Army, for an extension of two months, is granted MAJOR LOUIS BRECHEMIN, surgeon, Fort Sherman, Idaho.

The ordinary leave of absence granted CAPTAIN ISAAC P. WARE, assistant surgeon, under orders for duty at Benicia Barracks, Cal., is extended one month on account of sickness.

FIRST-LIEUT. GUY C. M. GODFREY, assistant surgeon, will be relieved from duty at Fort Sheridan, Ill., and will report in person to the commanding officer of the detachment of troops at Finn's Point, N. J., for duty at that place and at Fort Delaware.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING DECEMBER 18, 1897.

A. C. H. RUSSELL, surgeon, detached from the "Lancaster," and ordered home on waiting orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF COMMISSIONED OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING DECEMBER 16, 1897.

PECKHAM, C. T., passed assistant surgeon. Upon completion of duty at Vineyard Haven, Mass., to proceed to Pittsburg, Pa., and assume command of Service. December 14, 1897.

WHITE, J. H., passed assistant surgeon. To rejoin station at New York, N. Y., reporting at Bureau en route not later than December 22, 1897. December 13, 1897.

VACCHAN, G. T., passed assistant surgeon. Granted leave of absence for ten days from December 22, 1897. December 15, 1897.

YOUNG, G. B., passed assistant surgeon. Granted fourteen days' extension of leave of absence on account of sickness. December 15, 1897.

OAKLEY, J. H., passed assistant surgeon. To proceed to New Orleans, La., and report to Passed Assistant Surgeon J. H. WHITE for temporary duty. December 13, 1897.

NORMAN, SEATON, assistant surgeon. To report to Passed Assistant Surgeon J. H. WHITE at New Orleans, La., for temporary duty. December 13, 1897.

LAVINDER, C. H., assistant surgeon. To proceed to Delaware Breakwater Quarantine and report to the commanding officer for temporary duty. December 15, 1897.

TALKS ON THE HISTORY OF MEDICINE.

Dr. David Hunt, of Boston, will give four informal lectures on "The History of Medicine," by invitation of the Harvard Medical Alumni Association. The lectures will be given at the Harvard Medical School on successive Thursday evenings in January, beginning January 6th at 8 P. M. Members of the profession and students of the Harvard Medical School are cordially invited to attend.

J. S. STONE, M.D., Secretary.

SOCIETY NOTICE.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, December 27th, at 8 o'clock.

Dr. A. C. Klebs, by request, will present the subject of "The Diagnostic and Therapeutic Value of Tuberculin and its Derivatives." Dr. V. Y. Bowditch will open the discussion, followed by Drs. A. Worcester, H. F. Hewes and others.

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

RECENT DEATHS.

TREFFLE GARCEAU, M.D., M.M.S.S., of Roxbury, died suddenly on December 19th, aged sixty years.

PROFESSOR TARNIER, the eminent obstetrician, died recently in Paris, in his seventieth year. He took his Doctor's degree in 1837, and succeeded Professor Depaul in the Chair of Midwifery and Diseases of Women and Children in the Paris Medical Faculty in 1844. In 1889 a special Chair of Clinical Obstetrics was founded for him. In collaboration with MM. Chantreuil and Budin he produced a great work on obstetric medicine, which appeared between 1878 and 1886; and he was the author of important works on the hygiene of infancy. He took a prominent part in introducing antiseptic principles into midwifery practice and was the recognized leader in his special department of medicine in France.

BOOKS AND PAMPHLETS RECEIVED.

OPERATION FOR CORRECTING DEFORMITY OF THE NASAL SEPTUM.¹

BY F. E. HOPKINS, M.D., SPRINGFIELD, MASS.,

Laryngologist to the Springfield City Hospital, Fellow of the New York Academy of Medicine, Fellow of the Massachusetts Medical Society, etc.

DEFORMITY of the triangular cartilage, with attendant occlusion of the nasal passage, has long presented a difficult problem to the rhinologist. This difficulty is due to the resiliency of the cartilage and to the redundancy of tissue embraced in the wide bending from the straight line. I purpose to demonstrate to you a method of operating which, because of its efficiency, deserves to be more generally known. This operation restores the septum to its normal position and thus overcomes the obstruction to nasal respiration.

The evil results of nasal obstruction are so well understood that it is unnecessary more than to allude to the more prominent, namely, the interference with facial development, the lowered vitality which it induces, and the consequent interference with general development. In this paper I shall limit myself to the consideration of but one form of that obstruction, namely, deviation of the septum; and I shall invite your attention to the treatment of only that part of the septum which we find most commonly deflected—the triangular cartilage.

Allusion will be made to a few of the operations which have been more prominently brought before the attention of the profession, for the correction of this deformity; but there will be no effort to go into the literature of the subject—it would prove but wearisome—and a detailed description of but one method of operating will be given, that method adopted and perfected by Dr. Morris J. Asch, of New York. This method seems to me the most rational, and promises to secure better results than any other with which I am familiar.

As to etiology, it is probable that by far the most common cause of deviation of the septum is traumatism, and for the most part the injury is received early in life.

It has seemed to me that those cases in which the cartilage is not much thickened, being simply bent in a wide arc, making one nasal passage large and occluding the opposite one, were examples of a lesion beginning in early childhood, when the cartilage is yielding and more easily displaced; while those cases presenting marked thickening—*ecchondroses*—upon the convex side are examples of an injury received later in life, when the tissues are firmer and a much severer blow is necessary to displace the parts and the accident is followed by inflammation and a consequent piling up of tissue along the line of fracture.

It will be well to inquire into the condition which obtains when the nasal passage is wholly or partially obstructed in its anterior portion. The air-current passes into the lungs through the open nostril, drawn in by the active movement of the muscles of respiration. It enters with difficulty or not at all upon the obstructed side. One can thus readily appreciate the fact that at every inspiration, behind the point of

obstruction, a process of dry-cupping takes place with the consequence of determining an increased supply of blood to the mucous membrane and a thickening—hypertrophy—of this tissue. This thickening tends still further to close the affected naris, and in proportion to its narrowing a new force comes into play—atmospheric pressure. This force of fifteen pounds to the square inch exerted upon yielding tissue steadily forces the cartilaginous septum toward the outer wall of the affected side, until it rests upon it.

These are factors which must be borne in mind in performing any operation for the relief of the deformity under consideration. Not only must the resiliency of the cartilage be overcome, but good space must be provided upon either side, that the air-current may pass freely through each nostril. In one of my cases, a lad of nine years, the septum was over-corrected, and from deviating toward the left and occluding that side, it was forced over so far toward the right that that side was partially occluded, and had not this condition received early attention, the two forces, of tendency to vacuum behind the obstruction and air-pressure against the cartilage, would simply have changed a deviation to left for one to the right.

This influence of the never-ceasing, remorseless, so to speak, air-pressure upon the yielding, growing tissues of children is an interesting subject for study. The child who has nasal obstruction is, perforce, a month breather. The constantly open mouth permits of the exertion of air-pressure upon the hard palate and there results the high arched gothic-shaped palate; the upper part of the face is narrowed from the action of the same force, and this gives the peculiar facial conformation which in its more pronounced forms you have all observed.

The symptoms produced are, first, mouth breathing with its attendant discomfort of a congested and irritated pharynx, larynx and bronchi. In the pharynx we usually have a chronic follicular inflammation of the mucous membrane, the larynx is apt to be dry, which, aside from the annoyance given, affects the quality of the voice. The voice is, of course, further influenced by the lack of nasal resonance, which produces that wooden quality called nasal. The sense of smell is lost on the affected side.

Aside from these symptoms there result the structural defects first alluded to.

The diagnosis is easy as the lesion is situated so far forward that it can be seen without the aid of even a nasal speculum. One observes the obstruction in one nostril and examination of the other shows that to be correspondingly enlarged. There is a convexity upon one side, a concavity upon the other. The fact that adenoids are often associated with deviation of the septum need not be considered in examining a case. This is simply an added element to be considered in the care of the case. The object to be attained in performing operation for the relief of the condition under consideration is first to overcome the resiliency of the cartilage and then to retain it in its new position.

Adams attempted this by the use of strong forceps, which, though modified, have been retained by many operators, and having broken up the septum, kept it in position by ivory plugs.

Roberts, after the first step, retained the septum in position by a pin carried directly through from the concave side, then passing along the septum over the point of greatest convexity it enters the tissue again

¹ Read before the Springfield Medical Club at its regular meeting, March 10, 1897.

and is buried to a sufficient depth to hold it firmly. Roe uses a modified Steele's punch, then strong forceps. Moure seeks to correct the deformity by the use of electrolysis, inserting the negative needle into the tissue at the greatest convexity, the positive pole over it. And thus one could enumerate almost as many methods as there are men who have devoted special attention to this point.

I will now show you the instruments necessary for performing the Asch operation: they are a probe, to aid in examining the extent of the deviation and the degree of the adhesion of septum to outer wall, a gouge to break up adhesions, if such exist, the scissors for making the crucial incision through the septum, the strong forceps to overcome the resiliency of the septum, and the splint to retain it in position. After the septum has been thoroughly broken up by the use of the strong forceps, and then, with the finger forced far over into the opposite nostril, the tubular splint is inserted into what was the occluded side, to retain the septum in its new or vertical position. After hemorrhage has ceased, the patient is able to breathe through the hollow splint, so that a degree of nasal respiration is at once restored.

This splint should be worn for a period of about six weeks, that the septum may become thoroughly organized in its correct position. It must be removed daily for cleansing. After the first soreness has passed away, the patient can attend to this himself; in fact I have seen it done by children of ten years of age.

When the splint has been worn for a sufficient length of time to secure firm position of the septum, it then becomes necessary to remove any projections caused by the overlapping of fragments or due to the presence of spurs. The nares are then left smooth and the operation can be considered complete.

I report herewith a few cases illustrative of what can be accomplished by this method of operating:

CASE I. E. M., male, American, fifteen years of age. This case is perhaps deserving of a somewhat detailed description, for the obstruction to nasal respiration was almost complete and the evil results correspondingly marked. The lad was undersized, thin chested, and ill developed both mentally and physically. In weight he was much lighter than a brother two years younger. At school he made but poor progress, not being able to keep along with boys of his own age. He was unable to join in the active pastimes of his fellows because he was so quickly "out of breath." His appetite was not good and he would eat only soft food, mushes and bread soaked in coffee being favorite food. Meat and solid food he refused apparently because of the greater difficulty in swallowing, rather than because of any aversion to the taste of solid food. This difficulty in swallowing solids was due to the interference with respiration. The voice was entirely lacking in nasal resonance and there were many letters which he could not sound. The facial appearance was characteristic of nasal obstruction. The mouth constantly open and the face narrowed at the level of the malar prominences elongated his features and at the same time gave him an idiotic expression. Examination showed the septum deviated to the right and a large exostosis so that the right nasal fossa was entirely occluded. The left nostril was not enlarged in proportion to the deviation of the septum to the right, as there was hypertrophy of the inferior turbinated upon the left side filling up the enlarged space.

There was also pharyngeal obstruction due to the presence of adenoids and enlarged tonsils. The uvula was elongated. Happily for patients, it is rare to find so many lesions in the nose and throat of a single individual.

With Dr. Hooker's assistance, the Asch operation, as I have described it, was done December 27, 1895. He wore the splint seven weeks, and later the exostosis was removed and the other lesions above referred to given attention. The results in this lad's case can properly be spoken of as remarkable. He promptly began to take ordinary diet, he gained in strength and could run, skate and take part in boyish sports. At the end of six months he had grown four inches in height, and gained forty pounds in weight, — a promptness of rebound which suggests the removal of a weight. His appearance changed greatly for the better and his work at school became more nearly normal.

I have given this case at some length because it was an unusually good one to illustrate the evils of nasal obstruction and to show what can be done for its relief.

CASE II. D. B., male, American, nine and a half years old, was referred to me by Dr. Hooker March 9, 1896, for deafness and nasal obstruction. The deafness yielded readily to inflation, and arrangements were made to correct the obstructive lesion which consisted of a deviation of the septum to the left occluding this nostril. The obstruction to respiration was further aggravated by the presence of adenoids and enlarged tonsils. The septum was operated upon April 27, 1896, and the adenoids and tonsils removed under the same anesthesia. There was such redundancy of tissue in the septum, and the nose was so small that the septum was a little overcorrected though there is now good breathing space through the right nostril. The case is a successful one and the boy has grown rapidly since the operation.

(There is absence of history of traumatism in this case and the mother states that she discovered the septal defect when the child was three years old. He has a normal broad, hard palate.)

CASE III. A., male, American, aged twenty-one years. Deviation of septum to right with marked thickening, nasal fossa of this side being absolutely occluded. Adenoids also present. This patient was taken to New York about three years ago and was there operated upon with a trephine and saw, the large projecting overgrowth being removed. This afforded a measure of relief, but it did not sufficiently free the passage, and after the lapse of some time, the soft tissues, for reasons already explained, became so hypertrophied as to again obstruct respiration.

On August 29, 1896, the Asch operation was performed upon the septum, and the adenoids removed. The patient was under my observation but three weeks, as he left town for school on September 19th. From this time the care of the case was entirely in his own hands. He removed the splint twice daily for cleansing, and at the same time cleansed the nostril.

Examination, January 3, 1897, showed a free passage and a consequent restored nasal respiration.

Owing to the fact that previous to the operation so large a mass of tissue was removed, the septum was left unduly thinned at a certain level, and at this point there resulted a small horizontal perforation. The saw should not be used in these cases until after the

more radical operation has been performed, and the septum has become solidified in its new position.

CASE IV. A. H., male, of German parentage, aged sixteen years, referred to me by Dr. Hooker and with his assistance operated upon September 24, 1896. There was complete occlusion of the left nasal fossa by deviation and thickening of the septum. He also had adenoids. The cause of the septal deformity in this case was attributed to traumatism, a fall down stairs at the age of two years, and the external confirmation of the nose corroborates this statement, for it is noticeably deformed. The adenoids were removed and the septum straightened under the same anesthesia. Owing to the great thickening of the septum there was an unusual amount of trimming up to do after the tube was discarded. To-day the septum remains in the perpendicular plane in which it was left, and to his great comfort the patient breathes through both nostrils.

CASE V. G. K. P., male, American, aged twenty-six years. A slight, thin-faced, delicate-looking young man came to me September 23, 1896. His own diagnosis was hypertrophied tonsils, and the distress referable to his throat and the peculiarity of his voice made his diagnosis seem a fair presumption. There was in his speech not only a lack of nasal resonance but a quality of sound suggestive of the presence in his throat of a mass of adventitious tissue. Examination revealed tonsils somewhat hypertrophied, a chronic follicular pharyngitis and a throat congested and irritated out of proportion to the local lesion. The left nasal fossa was found entirely occluded by deviation of the septum. He could not remember when it had been possible for him to get air through that side. The throat symptoms seemed to me largely secondary to the enforced mouth breathing, and upon receiving this opinion he consented to an operation upon the nose.

It is worthy of remark in this connection, as bearing upon the evil effects of a lack of nasal respiration, that this young man belongs to a family possessing better than the average physical development. His father is above six feet in height, his two brothers are each six feet tall, his mother was at least of average height, yet he is much below the average height and of slight physique, having the pinched features and the high arched palate of a mouth breather.

With Dr. Bates's assistance I operated upon this case October 27, 1896. The after-treatment was unusually prolonged because of the patient's poor health, as he had frequent attacks of acute illness, tonsillitis, derangements of digestion, etc., none serious, yet of such frequency as to keep him reduced in strength. Early in January of this year his family had decided to send him to Bermuda for the rest of the winter, but about this time he began to improve and in a few weeks was able to return to business. To-day he is in better health than he has known for years. His father laughingly says, "George is going to be worth raising after all."

I shall have the pleasure of showing you this case.

CASE VI. E. B., male, French, aged twenty-six years, came under my observation November 8, 1896. Left nasal fossa completely occluded by deviation of the septum to that side, and by thickening of the cartilage. Asch operation performed November 12, 1896. The septum seemed fragile, which is rare, and upon use of the forceps for breaking up its resiliency

it crackled in an ominous way. No harm, however, was done save that a fragment at the angle of incision was broken off leaving a small perforation. Examination on March 4, 1896, shows both nostrils free and perfect nasal respiration.

One may be justified in considering every one of these cases successful and they include all I have operated upon by this method in this vicinity. They certainly are successful so far as restoring the function of respiration is concerned, and they are successful also in putting the septum permanently in a correct position. Time and patience are required, owing to the great resiliency of the cartilage, but most good results are obtained only at the expense of labor and vigilance.

NOTE. — Since the foregoing was written, I have performed the Asch operation in six additional cases, and in each of these free nasal respiration is restored.

CEREBRAL SYPHILIS.

WITH REPORT OF A CASE OF CHRONIC MENINGO-ENCEPHALITIS SECONDARY TO SYPHILIS.¹

BY CHAS. NORTON BARNEY, M.D.

THE patient whose case I am about to report entered the Massachusetts General Hospital first in July, 1895, on the service of Dr. Gannett, having been recommended for admission by Dr. James Putnam. She was at that time twenty-five years of age, and had already borne four children, the youngest of which was four years old. For a year she had had ulcers on the left leg. For two months before entrance these ulcers had been treated with mercury and iodide and had improved much, but were not yet entirely healed.

Since February, 1895 — that is, for five months — she had complained much of severe frontal headache, and at intervals, for periods of a week or more at a time, had appeared very dull and stupid. Some vomiting without relation to food, and occasional dizziness, but no paralyses nor twitchings. Headache, vomiting, dizziness and stupor, then, through the spring.

In July, nine days before entrance, mental dullness became more marked, headache very severe, her speech became "thick," and she often used the wrong words. The next day tingling in the little finger of the left hand, then of the whole left arm, and, later, paralysis of the arm. In two or three days more her face became drawn to the right, and the next day the paralysis involved the left leg. During the week, then, there were added to the previous symptoms of headache, vomiting, dizziness and stupor, a degree of motor aphasia, and left hemiplegia of gradual onset. There were also incontinence of urine and constipation.

Examination showed a fairly well-developed and nourished woman of small build, with dull expression and dull mental condition. She could answer questions, however, and recognize objects. There was slight internal strabismus at times. Movements of eyeballs were good. Pupils equal and reacting to light. Left facial paralysis not involving the upper segment. Paralysis also of the left arm and leg. There was some enlargement of glands in the neck, and scars of former abscesses. The knee-jerk was

¹ Read at a meeting of the Clinical Section of the Suffolk District Medical Society, October 20, 1897.

present on the right, but was not tested on the left because of the ulcers which extended from knee to ankle. No ankle-clonus on either side. Temperature, pulse and respiration were normal. Examination of the fundus of the eyes was negative. Examination of the urine negative. Blood examination showed no anemia and no leucocytosis.

During her stay in the hospital there were noted dulness, involuntary micturition, constipation, occasional headache and vomiting, aphasia, paralysis, and labial herpes. These symptoms rapidly cleared up under iodide administered by mouth and by rectum in doses pushed to 180 grains a day. The mental condition was the first to improve, becoming normal in four days. The paralysis disappeared first in the face, then in the arm, and last in the leg. The patient was under treatment one month. At the end of that time her intellect was perfectly clear, and she was able to walk several blocks with no help but a cane.

All the late summer and early autumn her husband considered her practically well. Catamenia did not appear in October nor in November. At this time she began to show slowness of thought and speech, failing memory, and "said odd things." Early in December she had an abortion and her uterus was curetted. Under iodide her mental symptoms improved. Later, however, headache became continuous and especially severe at night.

At the end of January, 1896, about a year after the first appearance of cerebral symptoms, she entered the hospital a second time, on the service of Dr. Fitz. She was unable to give any account of herself, but her husband stated that the chief symptoms had been mental confusion, thick speech and headache; and also, that for two days she had complained of tingling in the arm and lip, the symptoms which preceded the hemiplegia of six months before. This time, however, the tingling was on the right, whereas before it had been on the left. There had been no vomiting, and the eyes had been straight.

On examination, temperature, pulse and respiration were found normal. Nutrition and color not as good as at the examination six months before. Expression very dull. Questions were answered slowly or not at all. The eyes showed nothing wrong. Chest and abdomen were negative. There was ankle-clonus on the left, and a tendency to clonus on the right. Both knee-jerks were active. The patient moved the left foot only very slightly, and the right foot not at all. All movements were weak and sluggish, but possibly partly on account of hebetude.

The night of entrance she became noisy, was transferred to a private room, tied in bed, and given trional. Antisyphilitic treatment was begun. Mercurial ointment half a drachm by inunction every night, and iodide forty grains a day, to be increased fifteen grains each day. For the next week she was delirious most of the time. These days are perhaps worth reporting in detail.

February 1st. The temperature, previously normal, was now ranging between 99° and 100°, with a corresponding rise in the pulse. Patient shrieking when nobody was in the room, and crying when anybody entered. She was emotional and forgetful. Got out of bed unless tied. Slept only after hypnotics. Trional fifteen grains, and sulphonal ten grains were ordered to be given every morning and night if the patient were noisy.

On the second day she was in the same condition, shrieking and trying to get out of bed if alone and not under hypnotics. Hallucinations and delusions. Emotional. She shrieked all night, in spite of trional and sulphonal, and of hyosine given subcutaneously.

On the third day she slept in naps, but would shriek as soon as she awoke; and when anybody would come into the room she would cry out that she was being killed. She heard the voices of her friends and children, and had various other hallucinations. The daily dose of mercurial ointment given by inunction was increased to one drachm, and the order for trional and sulphonal changed to ten grains of trional and five of sulphonal every six hours if necessary. Three doses were required on this day.

On the morning of the fourth day she was awake and quiet. She screamed very little and got along with only one dose of the hypnotic.

On the fifth day she was crying, but not yelling. This day also she required only one dose of the trional combination.

The sixth day she was perfectly quiet and required no hypnotic. Headache was complained of and relieved by phenacetin.

On the seventh and eighth she took trional and sulphonal twice.

By the tenth she was rational, bright and quiet. She took a hundred and sixty-five grains of iodide, and showed no toxic effects from either iodide or mercury.

On the thirteenth she was taking one hundred and eighty grains of iodide and was kept at this dose from this time on. She had not required trional for two days and did not take it again. She was not noisy, and only occasionally had to be tied in bed.

By the eighteenth she had still shown no toxic symptoms from the mercury and iodide. It is interesting in connection with the question of the toxic effects of trional that this patient took considerable doses without evil result. She had improved remarkably and was discharged from the hospital to go home in care of her husband.

After this iodide treatment was neglected. She was thought to be pretty well, though all her mental faculties were still slightly dulled, and before long was trusted to walk alone daily to the house of a friend. One day she started out on her walk as usual, but got lost and turned up in Tewksbury. This was about three months after she left the hospital. Then a woman was hired to look after the house and children. The patient's mind was becoming more dull again; her memory was very poor; she was emotional and occasionally irritable. There were no hallucinations. Ptosis appeared, and disappeared. At one time she was jealous and threatened to kill her husband; but when he put a carving-knife in her hands, she broke out crying. After this he slept with her wrist strapped to his, so she should not get out of bed without his knowing it. At this time defecation and micturition were involuntary. She could not dress herself. She could not read. Her eyesight was good, but she could not tell one word from another. She had been getting distinctly worse all summer, but in August she was delivered of a living child, and then improved. The same improvement was noticed for a while after she had the miscarriage the previous December. The baby died in one month. The cause of death was stated as "cholera infantum."

October 3d I saw her for the first time since she had left the hospital. She was slow of comprehension, but talked fairly well; was polite, and apologized for the boisterousness of her children. She remembered nothing about the birth of her last child till certain circumstances were called to her mind; and after I left she remembered nothing of my visit. She had no delusions of grandeur, and no tremors of tongue and lips in talking. The only remains of the old hemiplegia were seen in a weakened grasp on the left side.

The next day she had a general epileptiform convulsion — the first. There was no warning. There was no cry. Her husband heard the thud of her fall, and, running in, found her unconscious, stiff, blue and twitching. The convulsion lasted about a minute and left her sleepy. Iodide treatment was now begun a third time.

Long before any nervous symptoms developed in this case the diagnosis of syphilis was made by the dermatologists. Syphilis was diagnosed at the patient's first stay in the hospital, from the irregularity and remittance of the symptoms and from the effects of antisyphilitic treatment. Again, at her second stay in the hospital the diagnosis of syphilis was made by independent observers. Her subsequent progress has confirmed the diagnosis. It is interesting that no history of infection can be obtained. The husband has denied secondary as well as primary symptoms, and presents no evidence whatever of syphilis on the most careful examination. The children are, and have been, perfectly healthy. The following data of past history and of family history are noteworthy. The patient has never been perfectly well. Throughout childhood she presented glandular and skin lesions. All her brothers and sisters died in infancy or childhood — most of them in convulsions. Her father and mother led very dissolute lives, but the causes of death could not be learned. In considering the possibility of hereditary disease the question comes up whether these facts are admissible as evidence.

ETIOLOGY OF CEREBRAL SYPHILIS.

Cerebral involvement in syphilis may occur at any time from a few months to twenty or even thirty years after infection. It is not necessarily a late manifestation. Over half the cases occur within three years, and as syphilitic infection is most common in young adults, so is the cerebral involvement. It is more likely to develop in cases where the skin lesions have been insignificant, perhaps because antisyphilitic treatment in these cases is more commonly neglected. Causes weakening the nervous system are thought to predispose to the localization of the disease in the brain. Such are trauma, meningitis and sunstroke, in addition to excesses and the other usual causes of neurasthenia.

PATHOLOGICAL ANATOMY.

Brain syphilis may result by extension of the disease from nodes in the bones of the skull, but is usually secondary to lesions of the membranes and vessels. These lesions consist of circumscribed gummata, large or minute, single or multiple, or of a diffuse gummatous infiltration in single or multiple patches. They extend from the membranes and involve the cortex, especially the anterior and middle portions of the base. The gummata are at first red

and soft, vascular and diffuse, but later become yellow and hard, fibrous, shrunken and more definitely circumscribed. Gummatous infiltration of arteries results in stenosis and thrombosis. Secondary results are hemorrhage, softening, or atrophy of the brain tissue.

SYMPTOMATOLOGY.

The symptoms of brain syphilis are variable on account of the variety in the nature and situation of the lesions, but there are certain general symptoms common to most cases and there are certain characteristics in the mode of development of symptoms.

Headache is ordinarily the first complaint. It is constant for considerable periods of time, and grows progressively more severe, though having remissions and exacerbations from day to day or week to week. It is, as a rule, more severe toward evening, and at night may be unbearable. *Insomnia* is another early symptom. *Torpor* comes next. The patient sleeps little, but is dull and stupid much of the time. He loses power of concentrating attention. *Memory* fails. *Dizziness* may be troublesome. These symptoms, like the headache, are progressive and remittent.

Finally, after days or months, aphasia, convulsions, paralysis, coma, delirium or dementia develop, and the other symptoms become less prominent. These symptoms also are slowly progressive, continuous or intermittent.

The *disturbances of speech* vary according to the centres involved. Any form of aphasia may be present, and may be the only localizing symptom. Motor disturbances are perhaps more frequent than sensory.

Paralysis also is more likely to be motor than sensory. The same lesion which produces the aphasia may extend and involve the adjoining motor area. The paralysis, unless due to hemorrhage, advances rather slowly, and has its exacerbations and remissions like the other symptoms. Loss of power is slight or complete. Hemiplegia and paralyzes of cranial nerves are the usual forms. Optic neuritis is common.

Disturbances of cranial nerves and convulsions are not often prominent symptoms in the same case, for the former are due to gummatous growths about the base of the brain, and convulsions, as a rule, to growths on the convexity.

Epilepsy, secondary to syphilis, may take the form of convulsions without loss of consciousness, loss of consciousness without convulsions, or both convulsions and loss of consciousness. It is to be distinguished from idiopathic epilepsy by the recognition of the existence of syphilis, by the precedent paroxysmal headache, by precedent or coexistent mental disturbance, optic neuritis, aphasia, hemiplegia or other paralysis, by the results of treatment and by the age of the patient at the first onset. Excluding premnia, hysteria and alcoholism the onset of epileptiform convulsions in a patient over twenty is probably due to syphilis. The aura and cry are not so often present as in idiopathic epilepsy.

Changes in mental condition due to syphilis are hebetic, delirium, coma, confusional insanity, hallucinations, or a dementia resembling general paralysis of the insane. There has been much dispute as to the nature of the dementia following syphilis. Mickle and Fournier conclude that syphilis produces a dementia resembling general paralysis, but that the two are not identical. A tenable view is that general

paralysis is not necessarily gummatous, but may be secondary to gummata as well as to other causes. The lesion is a chronic meningo-encephalitis resulting in atrophy of the cortex, or encephalo-malacia. Perhaps the division of general paralysis into an idiopathic and a secondary variety, as with epilepsy, would clear up the confusion. The characteristics of the dementia secondary to syphilis, as opposed to the idiopathic general paralysis of the insane, are as follows: Precedent syphilis; precedent headache, continuous, intense, worse at night; precedent or coexistent hemiplegia, aphasia, or paralyzes of cranial or other nerves, having the irregular characteristics of development and course already described. Greater variety and more fantastic combination or sequence of symptoms. Absence or inconspicuousness of the delusions of grandeur and of the tremors of face and tongue. And, finally, the beneficial effects of thorough antisiphilitic treatment upon many of the symptoms.

PROGNOSIS AND TREATMENT.

As prognosis in cerebral syphilis depends largely upon treatment these two will be considered together. Gummatous lesions are favorably influenced by iodide and mercury; secondary lesions are not. Treatment of the gummatous lesion is so effective that a case may present the very gravest symptoms of severe brain disease—delirium, convulsions, coma—and yet get well. Whereas treatment of the secondary changes is ineffective, though these are usually associated with syphilitic lesions susceptible to iodide. Prognosis, therefore, depends not so much upon the extent and situation of the syphilitic lesions as upon their age at the beginning of treatment and consequently the nature and extent of the secondary changes which they have set up. Earliness of treatment, then, is a most important consideration in prognosis. And as this depends upon the earliness of diagnosis the importance of making a correct diagnosis at the earliest possible period is supreme. As these patients are at any time liable to become blind, or to die in an epileptiform attack, or of hemorrhage from a gummatous artery, it is important also to get them under the influence of antisiphilitic drugs as soon as possible. For this reason mercury should be given as well as iodide, and both in doses rapidly increased to the limit of toleration. The mercury may be given in the form of mercurial ointment by inunction, in doses of half a drachm to a drachm or more every night, unless toxic symptoms appear; and at the same time iodide, beginning with thirty drops of the saturated solution a day, and increasing at first rather slowly to a drachm, and later, if toxic symptoms are not conspicuous, increasing very rapidly. If the patient is vomiting, the iodide may be given by rectum. Two hundred grains a day by mouth is not at all an extraordinary dose. Ten grains, three times a day, constitutes neither a reliable therapeutic test nor efficient treatment.

The practical points of this paper are the importance of the early diagnosis of cerebral syphilis, the importance of early treatment, treatment by mercury and iodide together, and both increased as rapidly as possible to the limit of toleration.

It is stated that the Emperor of Abyssinia has appointed a young Swiss woman as physician to his household. One can hardly realize that such a triumph of evolution is possible in that ancient land.

AN EXAMINATION OF FORTY-THREE PUBLISHED CASES OF OPIUM OR MORPHINE POISONING.¹

BY EDWIN J. BARTLETT, M.D., HANOVER, N. H.

Occasion.—The greater number were suicidal; a few were accidental; none were reported as homicidal.

Sex and Age.—Thirty-four were adults; nine were children. Of the adults 24 were male, 10 were female. Of the children seven were eighteen months or less (one was fifty hours; one was five weeks); two were over eighteen months.

Death or Recovery.—Thirty-six recovered; seven died. Of the deaths one was a boy; six were adults: one was a female; six were males. All of the cases but two had treatment; of the two, one was found dead in the morning; one died almost immediately.

Of the seven deaths, three seemed to be solely from the effects of the drug; one, complicated by previous medicinal doses of chloral, is described as from the exhausting effect of the remedial measures; delirium tremens, angina pectoris, uremia are complications in one case each.

Form of the Drug.—This is stated in 39 cases: laudanum, 19; morphine, 16; opium, two; soothing syrup, one; opium and morphine, one. Deaths following laudanum, two; morphine, two; opium, one; opium and morphine, one; unknown, one.

Quantity.—The quantity taken is recorded in 38 cases. Laudanum, fluid ounces, 3, 2 (2), $1\frac{1}{2}$ to 2, $1\frac{1}{2}$ (3), $1\frac{1}{4}$, 1 (5), $\frac{1}{2}$ (2), $\frac{1}{4}$, $\frac{1}{8}$, 3 minims; total 18.

Morphine, three teaspoonfuls, grains 51, 36, 30 (3), 20, 15 to 20, 16, 7, $1\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{4}$ (2), $\frac{1}{8}$, $\frac{1}{16}$; total 16.

Opium, grains 150, 6; total 2.

Opium, $2\frac{3}{4}$ gr. and morphine $\frac{1}{4}$ gr. in three days.

Soothing syrup, two teaspoonfuls divided.

The deaths followed the opium and morphine (no treatment); 3 oz. of laudanum (uremia); 1 to 2 oz. laudanum (delirium tremens); 150 gr. of opium; $\frac{1}{4}$ gr. of morphine (angina pectoris); $\frac{1}{8}$ gr. of morphine (after chloral); and one unreported dose; total, 7. All the other cases recovered.

Three minims (estimated) produced thirty-six hours' stupor in a five-weeks' infant, requiring artificial respiration nearly all the time for sixteen hours. One-sixtieth of a grain of morphine in two doses produced immediate alarming condition in a female adult somewhat reduced at the time, but tolerating one grain of opium at another time. On the other hand, thirty grains of morphine produced no effect whatever on an adult male, the only treatment being a somewhat late emetic.

Onset of Symptoms.—The time to the onset of disturbing symptoms is stated or implied in 19 cases. Five are described as "soon," "very soon," "immediate," "a few minutes"; one in fifteen minutes; six in thirty minutes; one in forty minutes; five in one hour; one in about two hours. Two of the fatal cases are in the "very soon" group, and the other five lack data; four of the early group resulted from the very small doses; the fifth is from six grains of opium. Of the six earliest cases, two were males and four were females. Of the seven latest cases, five were adult males, one was a female infant, one was an infant, sex not reported.

¹ Boston Medical and Surgical Journal, Medical News, New York Medical Record, Medical Journal, American Journal of Medical Science, 1882 to 1896 inclusive—fifteen years.

The conspicuous initial symptom is nearly always drowsiness, stupor, inability to stand; in one case the intoxication began with convulsions, coma later.

The interval before treatment is given in 34 cases, and ranges from nothing to thirteen hours; it does not seem to bear any definite relation to the subsequent gravity of the case. Of the seven fatal cases, however, two received no treatment, and in the others the interval was one hour, two hours, five hours (2), seven hours.

Termination of Case.—In the seven fatal cases death took place "in a few minutes," "next morning," 12 hours, 13½ hours, 36 hours, third day, three days. The second, third, fourth were apparently uncomplicated.

In 31 of the cases of successful treatment the time is given to partial recovery or encouraging improvement. It ranges from "a few minutes," 12 minutes, 15 minutes, 20 minutes to 21 hours; in seven cases it was from 11 to 13 hours. The average time was very nearly six hours from the beginning of treatment.

The time of complete recovery is stated in 25 cases, and ranges from 1, 3, 6, 12 hours to 4, 5, 5, 10 days in cases in which there was complete unconsciousness. The average was two days and two hours.

Pulse.—The condition of the pulse or heart is stated with more or less accuracy in 27 cases, four of which were fatal. "Little affected," "fair," two cases. "Just detectible," "absent," "pulseless," "barely perceptible," "feeble," five cases. "Full, slow" (3); "slow, strong"; "slow, intermittent"; "slow, 65"; six cases. "Rapid, feeble, intermittent"; "rapid, small, weak"; "rapid, irregular, weak"; "rapid, weak"; 110, 148, 156; 68, 84, 100, 120; 140, 148; 124 to 134; 96, 100; 85, 90, 100, 110; 110, 160; 150; 160, 130, 120; accelerated, 14 cases.

The fatal cases were 110, 148, 156; 124; 96, 100; "absent," four cases.

Face.—The appearance of the face is mentioned in 20 cases. Cyanotic, purple, dusky, livid, congested, 18 cases. Dull eyes, one case. Pale, one case. The pale case took three ounces of laudanum, was complicated with albuminous urine and uremia, and died on the third day; two other fatal cases are included in this list—one purple and one cyanotic.

Pupils.—The condition of the pupils is mentioned in 36 cases. Pin-point, dot, or some word indicating extreme contraction, is used of 22 cases; contracted is applied to 11 cases; total, 33. Dilated is applied to two fatal cases; one was not observed until after death, and the other died in a few minutes. Widely dilated is the only term applied to a non-fatal case, in which no mention is made of the treatment. In many cases dilatation soon after the use of atropia or belladonna is mentioned.

Mouth.—The condition of the secretions of the mouth is not mentioned in any case. In one case the lips and tongue are spoken of as black.

Temperature.—Mention of the temperature is made in only six cases. The statements are—normal; 102.2° in 12 hours; 96.4°, 104°, 103°, 101.3°; 101.6°, 105.8°; 103.5°, 104.5°. The second, third and fourth were fatal—complicated with delirium tremens, uremia, chloral and exhaustion, respectively.

Skin.—There is some description of the condition of the skin in 17 cases. Cold skin, six; cold and wet, seven; warm, moist, one; profuse sweat, one; dry, one; livid, one. Four of the fatal cases are in this list,

and were respectively—warm, moist; cold; cold, moist; dry.

Bladder.—The condition of the bladder is mentioned in only four cases. Thirty-eight ounces of urine was drawn in 15 hours; the urine was retained 24 hours; the urine was retained nine hours; the urine was retained 19 hours. The last three were infants.

Urine.—Urine is described twice, once as albuminous, once as scant and high-colored.

Respiration.—The condition of the respiration is mentioned in 35 cases. In four cases it is described as "little affected"; "rapid, shallow"; "26 a minute"; "10, 12, 14." In the other 31 cases the frequency is much diminished; in 12 it is described as stopping entirely; in 15 other cases it is noted as going down to 1, 2, 3, 4, 5, 6 or 8. They are described as "slow, gasping with occasional deep sighs"; "stertorous, intermittent"; "shallow, feeble"; "abdominal."

Stupor.—Complete unconsciousness is mentioned in 34 cases; three others died; unconscious, 37; partially unconscious, one; conscious, one; no symptoms, one; no data, three; total, 43.

The period of complete unconsciousness is mentioned or implied in about one-third of the cases, ranging from a few minutes up to 11, 12, 12½, 13 to 20, 20, 26, 36 (2) hours, with recovery. In one of these cases artificial respiration was maintained 12½ hours upon a man apparently dead; in another it was maintained 16 hours, with brief intermissions, upon an infant capable of making only slight and irregular efforts to breathe.

In one case the subject, though conscious, went to sleep while talking, after 46 hours.

Other Symptoms.—Of other symptoms little classification can be made on account of the meagreness of the data. Late vomiting is mentioned repeatedly, but cannot be separated from the effects of the remedial measures; one instance of vomiting is mentioned prior to the use of any remedies. Thirst is mentioned once or twice. Injection of the conjunctivæ once or twice. Inability to swallow is frequently mentioned or implied. Partial recovery followed by a relapse appears to be a frequent occurrence. Convulsions prior to stupor are mentioned once. Limpness or complete relaxation is mentioned six times. "Intense itching," "scratched leg," "rubbed face and nose," three cases.

After-Effects.—The scanty statements lead to the conclusion that the after-effects are usually slight and chiefly attributable to the strenuous measures employed to save life. Laryngitis, pneumonia, sore throat or cough are mentioned in four cases. Irritability, prostration lasting ten days, a rash, hallucination or mild delirium (presumably from atropia or belladonna) are mentioned; also sore mouth (from permanganate of potassium). In one case the attending physician ascribes the death to exhaustion from the violence of the treatment.

Treatment.—Aside from the maintenance of respiration, no particular remedial measure can be judged from these cases to have had especial value. The gravity and duration of the cases led to variety of treatment in the same case; nearly all the cases recovered under the most diverse treatment. Atropia and permanganate of potassium figure by far the most numerous; coffee very little; caffeine, amyl nitrite, strychnine, apomorphine, oxygen, whiskey, milk, electricity, etc., appear, and improvement followed them all.

Clinical Department.

CHRONIC HYDROCEPHALUS—PUNCTURE.

BY H. H. A. BEACH, M.D., BOSTON.

THE patient, a child nine weeks old, was sent to the Massachusetts General Hospital by Dr. Horace B. Marion, the condition having existed since birth. Upon entrance the temperature was 99.4°, pulse 180 and respiration 30. There was much deformity due to the forward and lateral bulging of the skull. The eyes were nearly hidden by the projecting and overlapping frontal region.

The skull had become distended to nearly twice its normal size through the separation of the frontal, parietal and occipital bones at the sutures, by the accumulation of serum. The child could not lift its head from the bed, but was constantly moaning or crying, and very restless—rolling the head from side to side. No convulsions.

The possibility of a tuberculous origin in this case, considered with the favorable results that have followed operative interference in tuberculous peritonitis and the desperate condition of the patient, prompted an attempt at relief by diminishing the intra-cranial pressure.¹

Under ether, an incision was made in the soft parts to the dura, and through an aspirator needle pushed about four inches in the direction of the lateral ventricle, 10½ ounces of colorless fluid were withdrawn.

On examination by Dr. W. F. Whitney, he reported "its specific gravity 1.007; a little white sediment; albumin, a trace; chlorides in large amount; sediment showed crystals of oxalate of lime and a very fine amorphous material with an occasional blood corpuscle and flat cell."

The distention was relieved by the aspiration. The patient became quiet, passed a good night, and on the two following days was much brighter, and the eyes could be seen. After that, the fluid reaccumulated. As the swelling and pressure increased the child became more restless and uncomfortable. She was crying and moaning incessantly, and each day becoming more feeble.

Thirteen days after the first aspiration a second was made. Fourteen ounces of fluid were withdrawn having the characteristics of that from the first puncture. The parietal bones then overlapped three-quarters of an inch. The thermometric variations were insignificant, excepting the night after the second puncture, when 101.5° was recorded. By the following morning the temperature was normal. The pulse was rapid during the whole time she was under observation, ranging between 150 and 170. After the first puncture it sank to 140, and after the second to 120, regaining rapidly as the fluid reaccumulated and pressure became re-established.

Within the following fortnight the fluid had accumulated to as great a degree as at first. Death followed in a few weeks. No autopsy.

The question of permanent drainage by canula was considered, but was not adopted in view of the tendency to an early and large return of the fluid. Compression by adhesive plaster after the withdrawal of fluid was not employed, as the relief from compression was evident. It seemed inexpedient to substitute a

fresh compression by plaster as suggested by Pott.² In his case the fluid reaccumulated in spite of the compression.

THE DIAGNOSIS OF TRICHINOSIS.¹

BY DR. R. C. CABOT.

ABOUT ten days ago I went to Cambridge to examine a specimen of blood. The impression I got was that I was to look for malarial organisms; beyond that I had no special impression as to the nature of the case. I did not find any malarial organisms. On making the differential count of white corpuscles, I found 27 per cent. of eosinophiles. I should not have had a guess as to the interpretation of this fact but for a communication of Dr. Thayer's about which he wrote me last spring and which has been published in the *Lancet* of September 25, 1897. They had last spring at the Johns Hopkins Hospital a typical case of trichinosis in which the diagnosis was easily made: great muscular pains and tenderness in special spots were present. A blood examination was made which showed a leucocytosis of 17,700 and an extraordinarily large percentage of eosinophiles, as high as 68 per cent. of the entire number of leucocytes. A piece of muscle was excised and showed the presence of trichinae. About two months after another case entered with a history of chills, fever, headache and backache, anorexia and weakness. There was edema about the eyes.

There was nothing special about the case by which the diagnosis could be made. The spleen was slightly enlarged, no diazo-reaction, a few rose-spots apparently on the abdomen. The case was supposed to be malaria and the blood and splenic pulp were carefully examined but no parasites found. The blood-count showed a slight leucocytosis, 13,000, which led to a differential count, and the same state of things was found as in the first case, a high percentage of eosinophiles. In both these cases trichinae were found in the muscles.

In the second case the diagnosis could hardly have been made without the blood-count for the symptoms were very indefinite. The patient recovered very easily, and shortly after the time of the blood examination he left the hospital and was not traced. With those two cases in mind, when I got this count of 28 per cent. of eosinophiles I telephoned to the doctor to find out the history of the case, which is as follows: The patient had been sent abroad this year for his health being somewhat run down, and went to Germany. While in Germany he did not improve very much, but in the middle of the summer had a very severe gastro-intestinal attack and after that a great deal of muscular soreness. When he returned in September his physician found what at first seemed to be neuritis with a great deal of soreness over the muscular bellies of the calves and biceps. That gradually lessened, but there came on edema of the face and hands. The diagnosis of trichinosis had suggested itself to the physician before the blood-count was made. He had not said anything about it to me because he wanted to see if it suggested itself to me independently. It would be very desirable to take out a piece of muscle to confirm the diagnosis, but the patient is getting well and I fear that he will not be willing to have it done.

THE SOFT CATHETER IN PLUGGING THE NOSE.

BY M. P. SMITHWICK, M.D., BOSTON.

EMPLOYMENT of the soft rubber catheter in plugging the nose requires no suggestion to those familiar with its use in nasal feeding.

Except in nasal operations under a general anesthetic, it is rarely necessary to plug the nose. Experts are usually correct in considering the frequency with which one resorts to this procedure in cases of spontaneous epistaxis to be inversely as his skill.

Last May a gentleman out of town, seventy-three years of age, a patient of Dr. C. F. Folsom, had been bleeding from the nose, with intermissions, for two days. Early in the attack the insertion of anterior plugs, by a physician who was called in the emergency, was followed by cessation of bleeding. This cessation was undoubtedly spontaneous. Later he found that a posterior nasal plug was necessary to control a vigorous return of the bleeding. He tried to insert this by means of a Belocque's canula, but was unable to pass the instrument.

When Dr. Folsom first saw the case bleeding had ceased again spontaneously. Later, when notified by telephone of a sharp recurrence, he asked me to insert a posterior nasal plug.

Blood was trickling from both nostrils and down the throat. Examination under good illumination failed to show the bleeding point, as a ridge on the right side of the septum met the turbinate and nearly occluded the passage. Even after the turbinate had been cocaineized the point could not be seen owing to the crookedness of the passage. It would have been difficult to pass a Belocque's canula and, if possible, very disagreeable to a nervous patient.

A medium-sized, soft-rubber catheter, threaded with waxed dental-floss, was passed quite easily. A carefully prepared piece of sponge, moistened with Monsel's solution, was inserted in the usual manner and allowed to remain forty-six hours. No plug was placed in the left nostril and no anterior plug was needed in the right. There has been no subsequent bleeding.

TECHNIQUE.

A soft-rubber catheter, a string more than twice the catheter's length (waxed dental-floss is excellent), a wire (the stilette of a gum-elastic catheter will do if the soft catheter is shortened), material for a plug, some styptic and a lubricant are necessary. A solution of cocaine is helpful and may be necessary to shrink the parts. Forceps are convenient.

An end of the waxed string wound about the end of the wire is passed through the catheter. Bring the ends of string together behind the catheter. Lubricate catheter; pass along floor of nostril, and, when the tip appears below the soft palate, grasp with forceps and draw it out of the mouth. Draw out the half of string not contained in the catheter. An end of the catheter carrying an end of string now projects from a nostril and from the mouth.

Attach the plug and draw it near to the catheter's tip, leaving outside the plug sufficient string to project from the mouth when the plug is in position. Then withdraw from the nose the catheter and, until the plug is fixed firmly in position, the string simultaneously. Considerable swelling, at least of the soft palate, will follow. If the plug is aseptic there need be no apprehension.

The soft catheter is available, of innocent appearance and effectual. It is as good as any instrument for the simple cases and the best for the difficult.

QUININE NOSE-BLEED.

BY ROBERT W. HASTINGS, M.D., BROOKLINE, MASS.

F. W., AGE seventeen, after playing foot-ball on Friday afternoon, sat down on the ground and became chilled. Within a few hours he had a very sore throat, fever, hoarseness and general pains. Slept but little that night. Saturday he gargled faithfully and the swelling in his throat and dysphagia disappeared. Slept well that night, but woke very hoarse and with some cough.

Thinking to throw off the approaching "cold," as he had often done before, he took six grains of sulphate of quinine. There was no apparent effect on the "cold"; but three hours later, after blowing his nose, he began to have nose-bleed, and had six sharp attacks within three hours. Pressure under the upper lip checked the flow each time in two or three minutes. On account of this recurrence he called at my office.

Examination showed a throat nearly normal; nose closed with dried mucus and blood; pulse full and hard, but not rapid; occasionally a beat not so full as the others; temperature 99.2° F.; skin rather dry; no tenderness of abdomen; no headache or other pain. He said he had had no ringing in the ears, headache, dizziness or disturbances of vision. Sense of fulness in his head was the same as before taking the quinine.

He was started on five-grain doses of bromide of soda, and given ten grains of Dover's powder and a codeia, chloride of ammonium, liquorice and cubeb cough-tablet for his "cold."

He had no further attacks of nose-bleed, but in two days was rid of his "cold" and back at school.

Reports of Societies.

CLINICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

E. W. TAYLOR, M.D., SECRETARY.

REGULAR Meeting, Wednesday, October 20, 1897, DR. W. F. WHITNEY presiding.

DR. CHARLES NORTON BARNEY read a paper on CEREBRAL SYPHILIS, WITH REPORT OF A CASE OF CHRONIC MENINGO-ENCEPHALITIS SECONDARY TO SYPHILIS.¹

DR. TAYLOR: Dr. Barney has covered most of the points in regard to this extremely important affection, but possibly I may reinforce one or two things he has said and quote a few cases. In the first place, I should entirely agree with him in laying stress on the importance of large doses of iodide instead of small ones. I have no doubt that oftentimes these cases go from bad to worse because heroic doses are not administered. Undoubtedly the disease provides a sort of immunity from the toxic action of the drug, and it may be given up to 300 or 400 grains a day without any serious

¹ See page 671 of the Journal.

toxic results. I have seen very remarkable results from the use of iodide alone, and iodide seems to me to be rather more important than mercury in the treatment of these cases. It is often possible to control the symptoms with the use of iodide in doses of from 150 to 200 grains a day.

The case of which Dr. Barney has spoken is one I saw a few weeks before he saw her the last time, with reference to possibly committing her to some institution; her mental condition was most peculiar, a curious apathetic state, indifference to her surroundings, and a remarkable forgetfulness of the fact of her recent confinement. She remembered events which occurred some years before, or before she had been so seriously ill, but had complete loss of memory for more recent events. Her treatment should, unquestionably, be prosecuted vigorously, and I have no doubt many of the symptoms of which she now complains might in that case be alleviated. It is evident in these cases, from the pathological anatomy, that after a certain point is reached, after the brain tissue or the cord tissue is once involved to the extent of destruction, treatment becomes less efficacious. The disease should be attacked early, before the syphilitic process has gone much further than the vascular stage. When the gumma is definitely formed in the brain it has the significance of a tumor, and the most that may be hoped is checking of the symptoms with but slight possibility of complete cure. This is peculiarly the case in lesions of a destructive sort, such, for example, as the syphilitic hemiplegia we so often see in young persons. I remember a case in which a patient was suffering from hemiplegia which had gone on for years. There was a fairly definite syphilitic history. This went on some months, when suddenly a spasm of one hand accompanied with epileptiform seizures of the Jacksonian type called attention to the probably syphilitic origin of the hemiplegia. Vigorous treatment controlled the spasmodic affection, which was practically relieved up to the time of his death. The hemiplegia, which was undoubtedly the result of a more serious vascular lesion, continued; and that was certainly only to a certain slight extent benefited. So far as the pathological anatomy is concerned, the lesion is usually cerebrospinal. It seems, perhaps, a little wrong to speak of cerebral or of spinal syphilis, since, as a rule, there is a combination of both lesions. Dr. Barney has distinguished the disease from dementia paralytica and from the analogous condition in *tabes dorsalis*. This is a distinction which should be borne sharply in mind, and which is perhaps not sufficiently recognized by the general practitioner, namely, that neither *tabes* nor *dementia paralytica* is properly a syphilitic disease. In both we suppose that syphilis is prominent in the etiology, particularly so in *tabes*, but pathologically there is no evidence whatsoever in either of these conditions of a tertiary syphilitic lesion. In *tabes* we have chronic degeneration in certain portions of the brain and spinal cord, and likewise in paralytic dementia, but purely of a parenchymatous sort, unassociated with evidence of previous syphilitic infiltration.

We have in addition a large number of cases, of which Dr. Barney's is an example, of so-called meningo-encephalitis, a term open to objection since the evidence of inflammation is not by any means apparent. It is in these latter cases of definite tertiary lesion in which the antisiphilitic treatment has so marked an effect. There seems to be no doubt that there is a variety of

conditions between these tertiary forms and primary degenerative states, of which *tabes* and *dementia paralytica* are examples, and that very likely paralytic dementia may in certain cases be associated with definite syphilitic lesion.

In conclusion, one more case which I saw a year ago, and about whom it was impossible to get any definite information on account of a curious mental state, which may be called, for want of a better term, a stuporous melancholia. His whole attitude was one of great depression, to such degree that he declined to speak, and had not spoken for months; he was apathetic; he sat in his chair and refused to go to bed or to help himself in any way—a perfectly immobile, helpless individual. Physical examination in his case showed a coincident cord lesion which probably was of syphilitic origin; and with that hint a vigorous anti-syphilitic treatment was instituted which led almost immediately to the clearing up of the mental state and to the possibility of his leaving the hospital. A short time ago he came to see me; the improvement was most remarkable. He had been in the interval under homeopathic treatment, receiving fifteen grains of iodide daily, which may have done something. On attempting to write the alphabet he failed, and had certain symptoms which, if he had been seen now for the first time, would suggest *dementia paralytica*. Undoubtedly in his case the primary lesion was syphilis, meningo-encephalitis, which has resulted in a certain degree of degeneration of cortical cells with partial recovery. These combined cases are certainly not infrequent.

DR. WHITNEY: As regards the possibility of there being two actions I do not see why that is impossible. We may suppose that the syphilitic virus, be it what it may, produces by one action the exudation and proliferation of cells with their subsequent necrosis, the conditions usually known as local syphilitic lesions and the gummata, whereas by another, in *tabes* and *dementia paralytica* it seems almost as if the poison picked out specific elements, causing their degeneration without any associated cell formation or an exudation. It, of course, is entirely speculative, but there may be a certain amount of analogy between that and the way some inorganic poisons act, which seem to have a selective affinity for certain cells, as, for instance, lead.

DR. BARNEY: It may be possible that in some of the cases of general paralysis and of dementia following syphilis, in which no gummata are found after death, gummata may have existed at some time during life and have cleared up, leaving only degenerative changes as the cause of symptoms.

The term "meningo-encephalitis" I used in the same way that the terms "interstitial nephritis" and "myocarditis" are used—meaning degeneration and not necessarily inflammation. The term "peri-encephalitis" is given by Dr. Wood, but this is equally objectionable. There is no term which covers the anatomical condition exactly.

DR. R. C. CABOT read a paper on

THE DIAGNOSIS OF TRICHINOSIS.²

DR. WHITNEY: I should like to ask how long this condition of excess of eosinophiles remained in Dr. Thayer's cases? Was it present when the man left the hospital?

DR. CABOT: Throughout the course of the disease; in the first case until death; in the second it was still

² See page 676 of the Journal.

marked at the time the patient left the hospital though not as marked as at some other periods.

DR. WHITNEY: Does a high percentage of eosinophiles ever occur as an idiosyncrasy?

DR. CABOT: I think not so high as that. Sometimes a high percentage of eosinophiles occurs in bronchial asthma, sometimes after injections of tuberculin.

DR. WHITNEY: Have you any theory as to the cause of the increase?

DR. CABOT: Dr. Thayer's first case was worked up carefully histologically, and they found a much larger percentage of eosinophiles among the leucocytes in the muscles than of the vessels, which led him to suppose the eosinophiles arose in the muscles and found their way to the blood from there. He noticed that the only two varieties of leucocytes affected were the eosinophiles and the polynuclear cells, and the polynuclear cells lost as many as the eosinophiles gained, suggesting that the polynuclear cells were transformed into eosinophiles. That is in accordance with some theories and very much against others as to the development of leucocytes.

DR. J. L. MORSE: Was there any absolute increase in the number of white cells?

DR. CABOT: Yes; in all these cases there was absolute increase. In a case reported by Packard³ there was no increase.

SCURVY.

DR. J. L. MORSE: I wish to call the attention of the members to the investigation which the American Pediatric Society has undertaken regarding infantile scurvy. As the disease is rather uncommon, the committee is very anxious to get as full a report as possible. I have here some blanks which I shall be glad to give or send to any who have had cases. I shall be glad if the members will call the attention of their friends to this investigation.

Recent Literature.

Hare's Practical Diagnosis. The Use of Symptoms in the Diagnosis of Disease. By HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. New (second) and revised edition. In one octavo volume of 598 pages, with 201 engravings and 13 full-page colored plates. Philadelphia: Lea Brothers & Co. 1897.

It is not long since we noticed the first edition of this book of Dr. Hare's. The second and revised edition follows the first at the short interval of a year, which indicates that it has quickly achieved a certain popularity and met a demand. In this edition faults where noted have been corrected and new facts added; the two indexes of the first edition have been combined in one. The author's plan, it will be remembered, was to present symptoms first, and then application to the disease second. The book consists of two parts, first, the Manifestation of Disease in Organs and second, the Manifestation of Disease by Symptoms.

THE CRAIG COLONY FOR EPILEPTICS. — Dr. Marie Louise Benoit has been appointed a medical interne in this institution.

ANNUS MEDICUS MDCCCXCVII.

THE year 1897 has not been marked by great medical events or discoveries, unless in medicine the bacillus icteroides and antitoxin serum of Sanarelli, and in surgery the procedure of forcible straightening of the spine in Pott's disease, introduced by Calot, and now being extensively practised in England and on the Continent, shall stand the test of time.

Medical progress during the year has, however, been substantial, and has been greatly facilitated by the free interchange of thought and opinion which has been made possible by the great Congresses of the year, and in particular by the International Congress at Moscow. Many of the discussions at this Congress will undoubtedly be fruitful in the broad diffusion of the additions to our knowledge, practical and theoretical, which were brought out during their continuance.

The year's experience has confirmed the value of the antitoxin serum of diphtheria, and given encouragement in the serum treatment of tetanus. We still await further proof of the substantial value of the serum treatment of plague, of the serum treatment of streptococcus infection, and of the tuberculin treatment of phthisis and the other forms of tubercular disease.

The year has been marked, as have none of the years recently preceding it, by the devastation of large tracts of country by disease and famine, as evidenced in the plague, cholera and famine-ridden peninsula of India; in these respects 1897 will be long remembered by the swarming native population as one of sickness, misery and death.

In the Western Continent the island of Cuba has presented a revolting picture of the evils of war among a semi-barbarian population; and yellow fever, small-pox and starvation have devastated the unhappy island, the conditions growing steadily worse with the apparently indefinite prolongation of the struggle.

The costly and fatal epidemic of yellow fever, which has for the first time since 1878 visited our own Southern territory, is one of the results of these conditions, and we may well inquire how long they are to be allowed to remain uncorrected.

The probability of legislation which shall either establish for this country a new department of public health, or of such reorganization of the Marine-Hospital Service as shall render its work in the protection of our coast-lines and frontiers from the invasion of epidemics is an encouraging result of the work of the American Medical Association and the American Public Health Association toward this end.

The recommendation to Congress, by President McKinley, of the appointment of a commission to investigate yellow fever, it is hoped may lead to substantial increase of our knowledge of this disease and of the methods by which it may be controlled.

The profession has lost this year, by the death of Sir Spencer Wells, one of its bravest members, a man to whom humanity owes an incalculable debt, and who was the true pioneer in Abdominal Surgery.

The death of Alarik Frithiof Holmgren has deprived it of one of its most eminent scientific members.

YELLOW FEVER.

To the perennial presence of yellow fever in Rio de Janeiro, Mexico and West Indian ports, which is a constant menace to this country, and in particular to the Southern sea-ports, there has been added this year a great increase of the disease in Cuba, owing to the continuance of miserable sanitary conditions, which have grown worse with the continuance of the war. The Spanish indifference to sanitation, as is evidenced by the fact that the main sewer of the city of Havana debouches in the harbor close to one of the important wharves, and that in a city of the size of Santiago there are no sewers at all, has given yellow fever a continuous hold in Cuba. When this fever-infested land becomes the home of unacclimated troops, who are kept for the most part crowded together in the cities, and when the agrarian population are herded into the towns in a starving condition, fever finds an all too easy prey in the famine-stricken population. These conditions, which prevailed during 1896, have been accentuated during 1897, as the continuance of guerrilla warfare has exhausted the food-supply of the island.

Yellow fever and small-pox have continued epidemic during the year, small-pox affecting most severely the natives of the country, and yellow fever the unacclimated Spanish troops. The Spanish military hospitals have been filled to overflowing with yellow-fever cases all through the year, and especially during the summer and autumn months.

Although during the autumn yellow fever has somewhat declined, the general death-rate, owing to the prevalence of dysentery and other diseases due to hardship and poor food, and of malaria, has continued to increase.

The total number of deaths in the city of Havana and the town of Regla during the month of November from all causes amounted to 2,317, equivalent to an annual death-rate of 139 per thousand inhabitants. In June there were 1,041 deaths; in July, 1,193 deaths, equivalent to a death-rate of 71.52; in August, 1,439 deaths, equivalent to a death-rate of 86.34; in

September, 1,778 deaths, equivalent to a death-rate of 106.68; in October, 2,272 deaths, equivalent to a death-rate of 136.32. Such figures as these are a sufficient comment on the sanitary conditions in Havana.

The danger to the United States from the extent of the prevalence of yellow fever in Cuba has been throughout the year fully realized by the officers of the Marine-Hospital Service; and from the very first of the year, the same regulations which had protected this country from an invasion of yellow fever during 1896 were continued in force. The inspection of passengers and baggage at Cuban sea-ports, the labelling of the latter, and the detention at quarantine of suspected vessels, have been kept up with the utmost vigilance throughout the year. Through the spring and summer, evidence of the increased extent of the disease in Cuba, and consequent danger of its introduction into the United States, was given by the number of vessels which it was necessary to detain at quarantine at New York or Southern ports owing to the presence of yellow fever on board, or the fact that cases of the disease had occurred during the voyage. The disease was constantly knocking for entrance at the sea-gates of the country, and at length, late in the autumn, for the first time since 1878, gained so extensive an entrance as to result in an epidemic which cost us many lives and a vast amount in money.

In Rio Janeiro, throughout the year, although more or less yellow fever was continually present, the cases have been few and there has been no serious epidemic.

In March the Norwegian bark *Homewood*, from Rio for Pensacola, Fla., had two deaths from yellow fever on the voyage and was held for disinfection at the Tortugas quarantine station. On April 22d, a passenger on the steamer *Finance*, from Colon, was found at New York to be ill with yellow fever and died at the New York quarantine station. In June a case of yellow fever was brought to quarantine at San Francisco by the steamer *City of Para*, from Panama. In August two cases of yellow fever were brought from Havana to New York on the steamer *Allianca*, and on September 22d two more cases were brought to New York from Colon on the *Finance*. In October the British steamer *Honiton*, from Progreso, Mexico, for Boston, was detained and disinfected at the Boston quarantine station, as three men had died from yellow fever on the voyage.

Yellow fever was carried, in April of the present year, from Guayaquil in Ecuador to Panama, and then across the isthmus from Panama to Colon. It was epidemic in the isthmus all summer.

A severe epidemic of yellow fever occurred in the island of Jamaica in October and November, several American residents and officers of British troops falling victims to the disease. Information was forwarded to quarantine stations in this country, by bills of health and other reports, and for a time the Boston Fruit Company's steamers ceased taking passengers

from Jamaica. The epidemic served to call attention to the fact that the British government enforced no compulsory report of contagious diseases on the island, so that the epidemic attained uncontrollable proportions before its outbreak was known.

About the 20th of August, at Ocean Springs, Miss., a summer resort on the Gulf Coast, the population of which is made up chiefly of excursionists from New Orleans, Mobile and the interior country, it was reported that five or six hundred cases of disease had occurred, which had been pronounced by experts appointed by the boards of health of Mississippi and Louisiana to be dengue. September 6th, Passed Assistant Surgeon Wasdin, of the Marine-Hospital Service, performed an autopsy on a case which had died with the symptoms of the prevailing disease and pronounced it yellow fever. An immediate exodus took place of the residents of Ocean Springs to their homes in New Orleans and the surrounding country, and a detention camp was established at a point on the Louisville and Nashville railroad, twenty miles east of Ocean Springs. John Guiteras, M.D., Professor of General Pathology and Morbid Anatomy, University of Pennsylvania, appointed temporary Acting Assistant Surgeon of the Marine-Hospital Service, visited Ocean Springs September 8th, and made the diagnosis of yellow fever in three cases, this diagnosis being subsequently confirmed in one case by an autopsy made by Dr. Wasdin. The large majority of the cases of prevailing fever, Dr. Guiteras pronounced to be dengue.

On September 8th a death from yellow fever occurred at New Orleans in the case of a patient who had just returned from Ocean Springs, and on September 10th the disease appeared at Scranton, Miss., and at Barkley, La., a river port on the lower Mississippi. By the 15th, Dr. Guiteras had established the diagnosis in several cases in Mobile, and at Edwards, Miss., the disease having been brought to the latter town direct from Ocean Springs. The disease also appeared at Biloxi and by September 15th, 14 cases had occurred in New Orleans. By September 19th it had spread up the Mississippi valley as far as Cairo, Ill., where two cases were reported. On September 23d one case occurred at Atlanta, in a refugee from Louisiana.

During September and early in October the disease spread in New Orleans; and by October 5th from 30 to 40 cases a day were being reported in that city. A large number of cases occurred in Edwards and Biloxi during September, but early in October the epidemic in these towns markedly diminished. In New Orleans, however, the disease increased during October, 60 cases being the highest number reported on any one day (October 20th). From this date until November 6th, from 30 to 50 cases a day were reported; but in the week ending November 11th, frosts were reported in the Gulf States and Mississippi valley, and a coincident sharp decline in the epidemic took place. During the month of October, 1,285 cases and 149 deaths had occurred in New Orleans. Early in November an epidemic of so-called dengue in Galveston and Houston,

Tex., was shown by Dr. Guiteras to be yellow fever; and during October a considerable epidemic occurred at Montgomery, Ala.

On November 29th, there were, for the first time since the epidemic begun, no new cases and no deaths reported in New Orleans. From the beginning of the epidemic to that time, 1,893 cases and 293 deaths had occurred in that city. From the beginning of the epidemic to December 1st, when it was practically ended, 4,385 cases and 462 deaths had occurred in this country, as computed from the tables in the Public Health Reports.

Throughout this epidemic the Marine-Hospital Service was active in carrying out rational measures for the detection and prevention of the spread of this disease. Numerous quarantine regulations of the shotgun variety were established, however, by the local authorities in many of the affected districts, which had the result of seriously crippling trade and travel, and even of preventing the government experts, who were taking all due precautions against conveying the disease, and were visiting infected points for the purpose of detecting and restricting the disease by rational measures, from reaching the points to which they were detailed. The results of such clumsy and inefficient methods tended to favor rather than to restrict the spread of yellow fever.

As to the source of the present epidemic, there is little doubt, and such is the published opinion of Dr. Guiteras, that the disease was imported from Cuba. It has become evident that a proper sanitary administration of the port of Havana is the only means for securing public safety of our Southern States, and also that under the present attitude of the Spanish government this condition is not likely to be obtained in the near future.

If the recent epidemic had begun early in the summer season, and not in the autumn, and a comparatively short time before the early frosts, its ravages, which in New Orleans at least were evidently beyond the control of the sanitary authorities, would have undoubtedly been fearful in extent and severity. A disposition of certain local authorities to doubt the early reports, and later to belittle the prospects of the disease spreading and becoming epidemic, undoubtedly was influential in allowing it to gain a foothold.

The conditions afford ample food for reflection on the necessity of eternal vigilance, the adoption of proper, and rejection of improper methods for the prevention of other such visitations as that through which we have just passed.

PLAGUE.

We have no need to remind our readers that the year 1896 closed with a fearful epidemic of plague in Bombay and Calcutta, which had already caused nearly two thousand deaths, and which was still increasing. The city was being depopulated by death and flight and the disease was spreading to the surrounding country, already stricken by famine. The increase and spread of the epidemic continued through

January and February, and by the end of January there had been 4,396 cases officially reported — 3,275 deaths from plague in Bombay alone, which was probably half the actual number. There was a serious epidemic at Kurrachee and the infection was spreading along the coast to the north of Bombay and into the interior. The disease, as will be remembered, first appeared in one of the most squalid quarters of the city and was believed to have been introduced by shipping from Hong Kong, in which city plague was epidemic during the autumn of 1896. At first only natives of the poorer classes, who, as is well known, live in filthy and crowded dwellings, where the most primitive sanitary provisions are disregarded, furnished the food for the epidemic; but soon the wealthier classes and even Europeans were attacked, and Dr. Robert Manser, the English physician in charge of one of the larger Bombay hospitals, fell a victim.

During the winter the local plague commission of Bombay established hospitals in every ward, started a house-to-house inspection and destroyed by fire uninhabitable and unsanitary houses, thus endeavoring to atone for their unwillingness to recognize that plague was epidemic at its inception, when vigorous sanitary measures might have stamped out the disease and saved thousands of lives, an inestimable amount of suffering, and an enormous loss of money, due to the paralysis of trade. Partly, perhaps, in consequence of these measures, and partly of the fact that the exodus from the city had left few fresh victims for the disease to feed on, a slight decline took place in Bombay during March, but its spread and virulence in the interior remained unabated.

Up to March 30th, when the epidemic had begun to abate, there had been 9,118 cases and 7,602 deaths from this disease in Bombay, according to the official reports, which figures were undoubtedly very far indeed below the actual number of cases and deaths. At this time it had markedly declined in the wards first affected and was evident in those parts of the city which it had reached last in its course.

With the return of refugees, which began during March, fresh cases began to be reported in parts of the city where the disease was supposed to have been stamped out by disinfectants and lime washing, and large numbers of the servants of European families fell victims. In April there had been 41 hospitals established for the treatment of plague in Bombay, and one of them, the plague ward of St. George's Hospital, was reserved exclusively for Europeans. Plague was then epidemic in Western India from 15° to 28° north latitude and had extended 150 miles into the interior.

By the end of April the population was returning to Bombay at the rate of 1,500 to 2,000 per day, and in spite of this fact a gradual decrease in the number of cases and deaths was reported. In the beginning of May there was a marked decline, and from the middle of June the number of deaths had fallen to 20 or 30 a week. The disease smoldered in that city

through July and August, the death-rate falling to 50 or 60 a month. During September and October there was a recrudescence, although no epidemic approximating that of the closing months of 1896 is reported. In Poona and other towns and country districts in the Bombay presidency, plague continued all summer, and in spite of the efforts of the officers of the Indian Medical Service had gradually spread further into the interior, and in October was active in the Punjab, in Cutch, the Central Provinces and Sind. At Poona a severe recrudescence took place in November and the disease claimed 1,100 victims a week, more, in fact, than at any time previously.

The epidemic of plague in India, although strenuous efforts were made to control it by the British military and civil authorities, was favored in its spread and continuance by the filthy habits and ways of living of the native population, a condition upon which a glaring light was thrown by the investigation which the pestilence in the affected districts, and in others its impending danger, made necessary.

The city of Calcutta, although it fortunately escaped the plague, was, as usual, the seat of a severe cholera epidemic, and an investigation disclosed frightful sanitary conditions prevailing among the native population. In the words of a writer in the *British Medical Journal*: "The question is forced into urgent consideration whether the natives of India — even the educated and enlightened — are fit to be entrusted with the responsibility of sanitary administration. Skilled and intelligent opinion in India has pronounced on this question very emphatically in the negative, and the facts displayed in this correspondence make it quite certain that the Governments of India must for some time to come either resume the care of the public health, or take such steps, in the way of supervision and command, as will ensure the proper and thorough execution of all those arrangements and contrivances which advancing civilization has demonstrated to be necessary for healthy existence."

The severity and continuance of the epidemic in India this year has naturally aroused anxiety lest an invasion of Southern Europe, particularly Turkey and the Mediterranean countries, should take place, and every precaution has been taken to prevent such a disaster. In this country early in the year, the cholera restrictions of the previous season were put in force against plague-infected ports. The Government of France imposed strict quarantine regulations and forbade the annual Mohammedan pilgrimage from its African dependencies. Austria imposed quarantine regulations, and the Italian government called an International Conference at Venice to consider measures against the importation of plague and cholera. The Turkish Superior Council of Health put in force stringent regulations with regard to the sanitary care of the pilgrims visiting Mecca from January to June, including quarantine at the Island of Camaran.

At the International Sanitary Conference which met at Venice in February, the origin and nature of

the plague, its means of transmission, duration of inoculation, means of disinfection and measures to prevent its entrance into Europe and bring it under control in case entrance should have been effected, were the subjects of discussion. Measures for quarantine, inspection and disinfection of vessels from infected ports were adopted, and were, it is understood, put in force by the governments signing the convention.

In April the British Governor-General of India, after some vacillation and delay, forbade emigration from the plague-stricken districts of India, thus preventing the Mohammedan pilgrimage to Mecca. As a result of this and of the precautions of the Persian and Turkish governments, no outbreak of plague took place in the Yemen during the pilgrimage. On June 10th, after the close of the pilgrimage, a slight outbreak of plague occurred in Jeddah, the port of Mecca, but it was limited to 16 cases and did not spread to Mecca or into the interior. Special sanitary officers were detailed by the Turkish government to get it under control.

Plague has been epidemic along the southern coast of China all through the summer of 1897 to an extent which it is impossible to estimate, as the government takes no census and keeps no record of births or deaths. In April plague was epidemic in Swatow and the surrounding country, and the government of Hong Kong took the unprecedented step of prohibiting immigration from the Swatow district. In April there was an epidemic in Macao, the Portuguese settlement but a few miles from Hong Kong. A few cases occurred in Hong Kong during the summer, but the worst visitation on the Chinese coast occurred at Amoy and the neighboring towns. In July the deaths in Amoy and four neighboring towns are believed to have reached a total of 400 daily. Almost all the attacks were fatal. The disease diminished during August and had practically died out in September.

Only one case of plague reached Egypt during the year, that being on board the British steamer *Bombay*, which arrived at Suez on March 31st. On the same date a case of plague was carried to the Russian port Theodosia on the British steamship *Baldwin*. In the autumn two cases of plague occurred at a sailors' hospital in London, both being sailors recently arrived from Bombay.

In Formosa plague was epidemic all summer, and a few cases were communicated to points on the Japanese coast.

SMALL-POX.

The most extensive visitation of small-pox in this country during the year has been that which began in Pensacola, Fla., during the winter, and later extended through the neighboring districts of Alabama,—Birmingham, Montgomery and Mobile being chiefly affected. As a result of extension from this source an epidemic occurred in Atlanta, Ga., and the surrounding country. Only a few scattered cases have occurred in other parts of the United States.

During the winter a mild epidemic occurred in Pensacola, Fla., and the surrounding districts, and the disease continued there, though in a mild form, through the spring and early summer, the last case being reported in July. The district which suffered most severely was Birmingham, Ala., and the surrounding country, where small-pox began in May and has continued the rest of the year, diminishing, however, during the autumn. Between May 8th and November 21st, 188 cases occurred, resulting, however, in only two deaths. During August there were 28 cases at Montgomery, Ala., and there have been during the year 33 cases at Memphis, Tenn. During the autumn there has been a not inconsiderable epidemic at Atlanta, Ga., 90 cases having been reported up to November 12th. The first case occurred in Atlanta on October 12th. All necessary sanitary measures have been enforced in the Southern cities where small-pox has appeared, and in connection with the Alabama epidemic, shotgun quarantine has been maintained by local authorities in the neighboring districts. The disease at Atlanta has been largely among the colored population, who have resisted vaccination and disinfection.

A few scattered cases have occurred during the year in widely separated parts of the country, about 20 cases occurring in New York and Brooklyn between March and August.

In May five mild cases occurred in Boston, the first case, from which the infection spread, occurring in a car-cleaner, who was employed in cleaning sleeping and parlor cars. Three cases, two of them fatal, occurred in June at Gloucester, Mass., the first patient being a man recently arrived from New York. There were three cases at Cambridge, Mass., in June and one at New Bedford in April. Other States in which scattering cases occurred during the year were Connecticut, Illinois, Michigan, Missouri, Ohio (14 cases at Toledo), Pennsylvania and Washington.

As is evident from the above report, the disease was widely scattered, and has followed no definite routes of travel. It is probable that the epidemic at Atlanta was communicated by refugees from the yellow-fever and small-pox epidemics in Alabama and Mississippi.

There was a slight epidemic at Montreal, Can., in July and August, 17 cases occurring and nine deaths. The outbreak was brought readily under control by the authorities.

In Great Britain and on the Continent there have been no notable epidemics of small-pox during the year, though the disease has been continuously present in London, and has occurred in Dublin.

In March the steamer *Delaware* brought 22 cases of small-pox from London to Rudy Island Quarantine. The crew were vaccinated, and the sick were removed and treated at Delaware Breakwater Quarantine.

During the first six months of 1897 a serious epidemic of small-pox prevailed throughout Japan. Between January 1st and 22d, 5,711 cases and 1,600 deaths were reported from all parts of the Japanese empire. The epidemic was of wide extent and the

type of the disease malignant. In February the steamship *Victoria* from Yokohama arrived at Port Townsend, Washington, having had a case of small-pox on board during the voyage, and the third engineer of the vessel afterwards developed the disease in Tacoma.

The arrival of steamers at Angel Island, the California quarantine station, reporting deaths from small-pox during the voyage was frequent, and detention at quarantine, disinfection of ship and cargo, and revaccination of passengers and crew was practised whenever necessary. In April three cases of small-pox were brought to Port Townsend Quarantine by the steamer *Alice A. Leigh* from Japan.

During April, though still very prevalent throughout Japan, the disease had markedly declined in Yokohama, Kobe, and Tokyo, the ports from which infection was most likely to be carried to this country by steerage travel.

In Cuba small-pox has been epidemic to a serious extent throughout the year. During a single week in January 990 cases and 108 deaths were reported in Havana. During one week in February there were 30 deaths daily from small-pox in Havana. During April and May the disease declined to a marked extent in that city, and through the summer and autumn months no increase took place.

In Naples, Italy, small-pox has been prevalent as it was during 1895 and 1896. In Zanzibar during July an epidemic occurred among the Indian and native population, though few Europeans were attacked.

CHOLERA.

The history of cholera this year presents little of interest, for the reason that it has fortunately been practically confined to the districts which are its constant habitat in India and China. During the first half of the year the plague-ridden city of Bombay almost entirely escaped it, and Calcutta, whose position at the mouth of the Ganges makes it the perennial home of the disease, was, as usual, the seat of the severest epidemic of the year. In that city it was moderately prevalent at the end of 1896, and during the winter months it gradually increased, until it reached its maximum in March, April and May, during which time there were nearly 1,500 deaths. The disease declined rapidly during the summer, and by October had almost disappeared. In Bombay, the disappearance of the plague during the summer was attended with an increase in cholera. In the month of August there were over 500 deaths from cholera in Bombay, but in September and October a considerable decline took place.

In Madras and Singapore cholera has been constantly present through the year, though there has been no epidemic.

In Ceylon there was a moderate epidemic during the last two months of 1896, and January, 1897.

On January 9th the P. & O. steamer *Nubia*, from Ceylon for Plymouth, England, arrived at the latter port, having had five deaths from cholera on the voyage, and having on board four convalescents from mild attacks of the disease. The patients were all members

of a regiment of troops homeward bound from Ceylon. The cholera was believed to have been contracted from eating infected fruit at Port Said, where the vessel stopped on December 29th, and not to have been brought from Ceylon, but the fact that two native members of the crew had died of dysentery on the way from Ceylon to Port Said, and that Port Said was not known to have been infected, point to the possibility of Ceylon having been the source of infection. Quarantine of the soldiers and isolation of the patients prevented any spread of the disease in Plymouth.

Cholera is known to have been present in Hong Kong during the year, and during the last six months has been mildly epidemic in certain Japanese ports. In July there were about 30 cases in Tokyo.

On March 22d the British ship *Clan McFarlane* arrived at Angel Island Quarantine, California, from Hong Kong, with 18 cases of cholera on the bill of health. Five days out of Hong Kong, one of the crew had died of diarrheal disease, and four more had been attacked soon after. The water-supply taken on at Hong Kong was known to have been bad, and believed to have been the source of infection.

The pilgrimage to Mecca this year was unattended by any outbreak of cholera. It seems probable that several reasons may have accounted for this, the chief of which was the prohibition, by the Indian Government, of the Mohammedans from leaving that country on account of the plague epidemic. The unusual precautions taken with regard to the sanitary care of the pilgrims by the Turkish Government for the same reason may have contributed to this result, as well as the activity of the other countries bordering on the Mediterranean against the transmission of infection by the pilgrimage.

BERI-BERI.

Beri-Beri is known to be always epidemic in the seaports of China and Japan, and this year has proved no exception to the general rule.

This disease has also been reported from disease-ridden Cuba throughout the year, being chiefly confined to the Chinese population in Havana. During the autumn it began to spread among the lower-class native population in Matanzas.

The usual number of cases have occurred during the year at Rio Janeiro.

A noteworthy outbreak occurred this year, as it has for several years past, in the Richmond Asylum, at Dublin, Ireland. The disease appeared in June, and by August 124 cases had occurred. Overcrowding and other unsanitary conditions are believed to be the reason for the tenacity with which beri-beri clings to this institution, though it is thought that it must have been first introduced there by patients, or in food and clothing from some Eastern country. Steps were taken during the year to relieve the overcrowding and improve the sanitation.

Beri-beri was brought to the port of Cork, Ireland, in August by a vessel arriving from the west coast of Africa.

In November the whaling bark *Greyhound* arrived at New Bedford, Mass., with five cases of beri-beri on board, and having had three deaths from it during the last month. The bark was returning from a five years' whaling voyage.

TYPHUS FEVER.

In March there was an outbreak of typhus fever in Tokyo, Japan, 47 cases and 37 deaths occurring up to March 1st.

In October two cases of typhus occurred in San Francisco. The origin of the infection was not discovered.

TYPHOID EPIDEMICS.

In September and October an epidemic of typhoid fever took place at Maidstone, Kent, England, which was due to the infection of a large part of the water-supply of the town by the drainage from a camp of hop-pickers from London. The camp was pitched in a field draining into a pond from which part of the water-supply was taken. When the epidemic began to decline, late in October, there had been about 2,000 cases, and during October there were 20 or 30 deaths per week.

In October and November there was a severe epidemic of typhoid at King's Lynn, a port of about 8,000 inhabitants at the mouth of the River Ouse, in Norfolk, England. This was also traced to infection of the town water-supply with sewage, being surface drainage from a village situated on the banks of the Gayton River, from which the town supply is taken.

In Belfast, Ireland, an epidemic of typhoid occurred in November.

Marseilles, France, was the seat of an epidemic of typhoid in May. There were at one time 1,000 cases in the city. An impure water-supply was probably the source.

CEREBRO-SPINAL MENINGITIS.

During the winter and spring of 1897, an epidemic of cerebro-spinal meningitis occurred in Massachusetts, the extent of which, owing to the fact that physicians throughout the State do not notify their local boards of health of the occurrence of this disease, is not definitely known. Numerous cases were treated at the hospitals in Boston, 47 cases being treated in the Boston City Hospital from December 30, 1896 to June 1, 1897. The mortality in these 47 cases was 72 per cent. Lumbar puncture was done in a large proportion of these cases, and in most of them the diplococcus intracellularis meningitidis of Weichselbaum was found in the cloudy serum of pus obtained. An investigation is in progress by the Massachusetts State Board of Health, into the extent of the epidemic and it is to be hoped that some light may be thrown upon the modes of dissemination of the disease.

During the last six months of the year the disease has not died out, and cases have been constantly under treatment in the Boston City Hospital.

ANTITOXIN IN DIPHTHERIA.

The reports on the use of antitoxin in diphtheria which have appeared during the year have continued to show a reduction in mortality amounting to the saving of thousands of lives by this invaluable product of modern medical science.

The second report of the collective investigation of the American Pediatric Society on the antitoxin treatment of laryngeal diphtheria in private practice, gave the results of 1,704 acceptable cases of laryngeal diphtheria in which antitoxin was used. Of this total nearly 61 per cent. were not operated upon, and gave a mortality of 17.18 per cent., a result which, though good, the committee rightly believes can and ought to be improved upon. Of the cases operated upon the mortality was 27.24 per cent. The mortality in both classes of cases it is believed might be reduced were the standard of the antitoxic serum assured, and were both physicians and friends of patients less timid in its use.

The report of the Imperial German Board of Health upon the use of diphtheria antitoxin in the hospital in the German Empire from April, 1895, to March 1, 1896, published early in 1897, showed a fall in mortality from an average of 26.7 per cent. in 157,724 cases treated in the twelve years from 1883 to 1895, to 15.5 per cent. in 9,581 cases treated during the period mentioned above.

Every additional contribution to the statistics of the treatment has confirmed the fact which was demonstrated when the diphtheria antitoxin first came into use, that the prospect of success in a given case depends very much upon an early beginning of the treatment.

The mortality from diphtheria and croup in Massachusetts from 1891-94 had been 28.3 per cent. in 13,332 cases. The mortality in 1,209 cases since antitoxin has been employed has been about 13.5 per cent.

The report of the Metropolitan Asylums Board of London on the antitoxin treatment during 1896 shows that the favorable results which were reported during the first year of the use of antitoxin have been maintained.

The report closes with the following conclusions as to the effects of the treatment arrived at by all the signatories except one:

(1) A great reduction in the mortality of cases brought under treatment on the first three days of illness.

(2) The lowering of the combined general mortality to a point below that of any former year.

(3) The still more remarkable reduction in the mortality of the laryngeal cases.

(4) The uniform improvement in the results of tracheotomy at each separate hospital.

(5) The beneficial effect produced on the clinical course of the disease.

All other reports from whatever source have confirmed the value of the antitoxin in diphtheria.

ANTITOXIN IN TETANUS.

Partly perhaps on account of the rarity of tetanus, which is surprising considering the number of punctured and dirty wounds likely to furnish breeding ground for the bacillus, and partly perhaps from the difficulty or securing a supply of suitable antitoxin in time to be of effective service, but few reports of tetanus treated by antitoxin have come under our notice this year. A few cases of recovery from tetanus in which the inoculation took place by wounds about the face and head, the "head tetanus" which was formerly found particularly fatal, have been reported under antitoxin treatment. In general the cases of tetanus which have recovered under antitoxin have not been of the most acute and fulminating type of the disease, in which the absorption of the toxin is so rapid that it is impossible to supply enough antitoxin units to neutralize it. However, there is reason to believe that certain cases on the border-line between the most acute and chronic forms of the disease have recovered under antitoxin treatment and as a result of it.

The difficulty of securing a serum of sufficient strength (and in order to be effective against the rapid production of toxins in the body it must be extremely concentrated) has rendered effective preparations of tetanus antitoxins rare and expensive. In this disease an inferior or weak preparation will prove of no service whatever, and in order to secure good results, it is especially important to begin the treatment at the earliest possible moment and with a preparation of known strength.

Two cases of traumatic tetanus have been treated during the year at the Boston City Hospital with the antitoxin serum prepared under the auspices of the Massachusetts State Board of Health. One a moderately acute case, but infected through a wound of the face, recovered. The other, belonging to the most fulminating type of the disease, succumbed in spite of copious doses of the serum.

There is reason to believe, on the whole, that the recovery in the first case was due to the serum, for although the symptoms were not of the most rapidly progressive type, they appeared early (within five days after the infection), and as noted above, the infection was through a wound of the face, and was attended by facial paralysis.

Lambert¹ gives a mortality for all cases of tetanus treated without antitoxin, of 60 per cent., and a 30 per cent. mortality for all cases treated with antitoxin.

Goodrich² gives the mortality in 113 cases treated by antitoxin and of a like number treated by antispasmodics at about 63 per cent., but calls attention to the fact that fatal cases treated without antitoxin are not reported, while those treated with antitoxin usually are.

ANTISTREPTOCOCCIC SERUM.

The value of the serum treatment of streptococcus infection is still *sub judice*.

Steele³ has tabulated 26 cases in which the antistreptococcic serum was employed in puerperal septicemia, of which 16 recovered and 10 died. It is noteworthy that in 14 of these cases intrauterine douches or curettage were employed in addition to the serum treatment. If four cases in which the treatment was

begun late (from the twenty-second to the twenty-fifth day in two of them), and all of which died, be excluded, we have six deaths to 16 recoveries, or a mortality of 18.18 per cent. An early administration is admittedly essential in order to secure good results in these cases; but there are so many other causes for transitory rises of temperature during the puerperium beside streptococcic infection, that in case the serum is given early and a rapid recovery ensues, we remain in doubt as to whether the disease was a true streptococcus infection. It is important to secure, if possible, a bacteriological examination of the uterine discharges with reference to the presence of the streptococcus.

Cases of lymphangitis and of erysipelas have been reported during the year as recovering under treatment with antistreptococcic serum, but, as is well known, erysipelas results in a spontaneous recovery in a very large percentage of the cases.

Several cases of malignant endocarditis have been reported as treated with antistreptococcic serum with some measure of success.

THE BACILLUS ICTEROIDES OF SANARELLI.

In July of the present year, Prof. G. Sanarelli, director of the Institute of Experimental Hygiene in the University of Montevideo, published, as a result of investigations carried on at the island of Flores and at Rio Janeiro, an account of his isolation and cultivation from the blood and tissues of yellow-fever victims a bacillus which he considered that he had proved to be the specific organism of yellow fever. He had isolated it in 58 per cent. of the cases, and attributed his failure in the remaining number to the fact that the toxin produced so early a death of the organism that no extensive multiplication took place. Death was also attended by the intervention of secondary infections. Heat, moisture, darkness, want of ventilation, are the conditions favorable to the growth of Sanarelli's bacillus; and common moulds are its great protectors, and exert some influence most favorable to its growth.

Surgeon-General George M. Sternberg, U. S. N., has recently published⁴ a further account of his bacillus α , isolated by him in connection with yellow fever during researches pursued at Havana by the United States yellow-fever commission between 1887 and 1889, and which he considers probably identical with the bacillus icteroides of Sanarelli.

In spite of the brilliant and laborious work of Sanarelli, his claim that the bacillus icteroides is the specific organism of yellow fever, cannot be said to have been proved; nor does the bacillus α , of Sternberg, satisfy the requirements which must be fulfilled by an organism which claims to be the specific cause of yellow fever. There is a possibility that ultimately both may be proved to be secondary invaders.

The President's recommendation to Congress that a commission be appointed to investigate yellow fever, will, it is to be hoped, result in the early authorization by that body of the appointment of such a commission, made up, as suggested in our editorial of December 16th, of men who should ably represent clinical, pathological and bacteriological science. The labors of such a commission ought to result in a broadening of our knowledge of the disease, and of our methods of controlling it, even if the question of the specific organism should remain unsettled.

Koch's NEW TUBERCULIN.

On April 1, 1897, Professor Koch published in the *Deutsche Medicinische Wochenschrift* the description of a new and improved tuberculin, the result of several years of study and experiment. This new product was believed to have been purified by complicated processes of trituration and filtration of dead bacteria and other impurities to which the severe constitutional reactions and occasional abscess formations resulting from the use of the old tuberculin were thought to have been due. In short, it was supposed to possess the curative properties of the old tuberculin without its irritating effects. Of the new tuberculin Koch claimed to have established by trial on a large number of suitable cases of lupus and early phthisis that its action was much more effective than that of the former product. It was not necessary, in order to produce immunity by the new tuberculin to administer enough to produce a reaction, and the disagreeable effects of the old tuberculin were according to his report, not seen with the new.

Since the publication of his article, and the simultaneous marketing of the product by a large German chemical establishment, great activity has been displayed in the trial of the new product in German and other European clinics, and it has been also employed to some extent in this country.

The early reports from its use, which were made in July by Schulz, of Bonn, and Fräukel, of Berlin, were not encouraging and failed to confirm the expectations aroused by Koch's paper. In many instances the unpleasant effects, reaction, etc., of the old tuberculin were found to characterize the new. Chills and high fever developed, and the constitutional reaction was fully as severe as under the treatment with the old tuberculin. There was no satisfactory evidence of a definite influence of the treatment upon the course of the disease.

Doutrelepoint, of Bonu, reported in August, as a result of trial in fifteen cases, that the new tuberculin had a favorable effect in lupus, but that great care in the increase of the injections had to be taken in order to avoid undesirable reaction.

Leick tried tuberculin in fifteen cases of pulmonary tuberculosis, and noted improvement in but three.

Herzefeld found improvement to result in but one out of seven cases of laryngeal tuberculosis.

Baudach, physician in charge of a sanitarium for tuberculosis, treated twenty patients with tuberculosis of the lungs, and found the treatment in general to be followed by good results, and productive in a number of cases of more rapid improvement than would otherwise have been the case. His patients had the benefit of the most favorable possible conditions for improvement, even if tuberculin had not been employed.

Nencki, Maczewski and Logucki⁵ demonstrated the contamination of the new tuberculin with pyogenic cocci, and found decided reaction and fever resulting from its use.

Malcolm Morris, of London, and Lassar, of Berlin, report favorable results from the use of the new preparation in lupus.

Cutler, of Boston, has reported in the *JOURNAL* marked improvement and gain in weight in two cases treated by him with the new tuberculin. Hewes, of

Boston, has treated four cases, two of which gained in strength and spirits under the treatment, but all lost weight, and the subsequent history of these cases was not favorable.

It is a self-evident fact that sufficient time has not elapsed to enable a definite opinion to be formed as to the curative effect of the new tuberculin. As to whether its action is in general beneficial, sufficient evidence has not accumulated, and the question must for the present be regarded as undecided.

It has certainly been proved that the new product is not as free from danger of producing reaction as Koch had led us to expect. The complication and delicacy of the procedures necessary for its preparation, render it extremely difficult to secure a uniform product. Although it is to be hoped that good results may be attained by the use of the new tuberculin in the future, patient and long-continued trial will be necessary to settle the question.

THE RÖNTGEN RAYS.

During 1897 great activity has been displayed in the perfection of radiographic and fluorescent apparatus, with the result that those who are expert in the invention and practical employment of such apparatus are enabled to secure clearer and larger pictures than ever before. The rays have proved of value in the detection and sometimes the rectification of obscure deformities following fracture and dislocation, in the location of foreign bodies in the body, and in particular in the esophagus and other portions of the gastrointestinal tract. Foreign bodies in the eye have been successfully located by their use.

The work of their application to the diagnosis of internal disease, particularly of the chest, has been actively pursued during the year, and they have proved of value in the diagnosis of thoracic aneurisms and other tumors, tubercular processes in the lungs, and in accurately mapping out the extent of cardiac enlargements. With regard to proving of service in the early diagnosis of phthisis, it may be said that, in the early stages when the disease is simply a catarrhal bronchitis at the apex, for instance, and no solidification has occurred, the interference with the rays would hardly be sufficient to produce a shadow, although the stethoscope would reveal the presence of fine crackling râles.

It is improbable that the rays will prove of value in the diagnosis of phthisis in the early and therefore the most important stages, until the apparatus is perfected so that it will bring out much finer differences in the consistence of tissues than it does at present.

MEDICAL CONGRESSES AND MEETINGS

The International Medical Congress at Moscow, August 19th, fostered and supported with lavish liberality by the Russian Government, and attended and participated in by the leaders of European medical science in its varied departments, was a gathering which will long be notable in medical annals for the advanced and progressive character of the scientific work there reported.

The International Congress of Leprologists in Berlin, October 11th, was productive of important results, in that Hansen's bacillus was admitted to be the cause of the disease, and isolation of lepers agreed upon as the most important means for preventing its spread.

The meeting of the British Medical Association at

⁵ Presse Medicale, No. 46.

Montreal was of great interest to American physicians, and the proceedings contained much in the line of medical and surgical progress.

The Fourth Congress of American Physicians and Surgeons, including fourteen special Associations, was held in Washington, D. C., May 4, 5 and 6. The Fiftieth Meeting of the American Medical Association, was held in Philadelphia, June 1 to 4. The American Society of Naturalists and the affiliated societies met at Ithaca, N. Y., on December 28, 29 and 30. The other societies meeting with the Naturalists were the Association of American Anatomists, the Association for Botanical Morphology and Physiology, the American Morphological Society, the American Physiological Society, the American Psychological Association, Section H (Anthropology) of the American Association for the Advancement of Science. The American Association of Obstetricians and Gynecologists, met at Niagara Falls, August 17 to 20. The Association of Military Surgeons of the United States, met at Columbus, O., May 25 to 27. The Mississippi Valley Medical Association, at Louisville on October 5 to 8. The Southern Surgical and Gynecology Association, at St. Louis, Mo., November 9 to 11. The Tri-State Medical Society of Alabama, Georgia and Tennessee, at Nashville, Tenn., October 12 to 14.

An International Congress of Forensic Medicine was held at Brussels, August 2 to 7, and a Second International Congress of Sanitation and Hygiene of Railways and Navigation at Brussels, during September. The Sixty-fifth Annual Meeting of the British Medical Association was held at Montreal, August 31 to September 3. The Fifteenth German Congress of Internal Medicine was held in Berlin, June 9 to 12. The Twenty-fifth Annual Meeting of the German Surgical Association at Berlin in May. The Eleventh Congress of the French Association of Surgery was held at Paris, on October 18. The Association of German Naturalists and Physicians at Brunswick, in October. The Seventh Congress of the German Gynecological Society was held at Leipzig, June 9 to 11, the French Congress of Alienists and Neurologists in August at Toulouse.

LECTURES.

In connection with established lectureships in the United States and Great Britain, the following lectures and orations were delivered:

The Shattuck Lecture before the Massachusetts Medical Society, on "The New Surgery," by David W. Cheever, M.D., LL.D.; the Bradshaw Lecture on "The Correction of Certain Deformities by Operative Measures upon Bones," by Alfred Willett, F.R.C.S.; the Hunterian Lectures on "The Pathology and Surgery of Intussusception," by D'Arcy Power, M.A., M.B. Oxon., F.R.C.S.; the Harveian Oration on "Science and Modern Civilization," by Sir William Roberts, M.D., F.R.S., F.R.C.P., Lond.; the Hunterian Oration on "John Hunter as a Surgeon," by Christopher Heath, F.R.C.S.; the Croonian Lectures on "The Means by which the Temperature of the Body is Maintained in Health and Disease," by W. Hale White, M.D., F.R.C.P., London; Supplementary Croonian Lecture on "Points Connected with the Pathology and Treatment of Diabetes," by F. W. Pavy, M.D., LL.D., F.R.S.; the Lumleian Lectures on "Some Problems in Connection with Aphasia and other Speech Defects," by H. Charlton Bastian, M.A.,

M.D., Lond., F.R.S.; the Goulstonian Lectures on "The Chemistry and Pathology of Gout," by Arthur P. Luff, M.D., B.Sc., F.R.C.P.; the Bradshaw Lecture on "Prognosis in Heart Disease," by E. Markham Skerritt, M.D., F.R.C.P.; the Milroy Lectures on "Quarantine," by W. Collingridge, M.A., LL.M., M.D., the Ingleby Lectures on "The Operative Treatment of Cancer of the Breast," by Bennett May, F.R.C.S.; the Lettsomian Lectures on "Diseases of the Nose and Throat in Relation to General Medicine," by F. De Havilland Hall, M.D., F.R.C.P. Lond.; the Morison Lectures on "The Anatomy and Physiology of the Nervous Mechanism of the Viscera," by Dr. Alexander Morison; the Harveian Lectures on "Syphilitic Diseases of the Eye and its Appendages," by Henry E. Juler, F.R.C.S., Eng.

NECROLOGY. — FOREIGN.

P. Ambrosoli, M.D., physician-in-chief to the Maggiore Hospital of Milan, died in September, aged fifty-four.

Prof. Oscar Boer, of Berlin, known for his work on infectious diseases, died in September.

Ernest Brand, M.D., the modern advocate of the cold-bath treatment of typhoid fever, died at Stettin, Germany, on March 8.

Sir John Bucknall, F.R.S., the author of important contributions to neurology and insanity, formerly editor of the *Journal of Mental Science* and one of the editors of *Brain* and of the *British Medical Journal*, died at Bournemouth on July 20, aged seventy-nine.

Louis Pascal Casella, the inventor of the clinical thermometer, died at Highgate on April 23, aged eighty-six.

Dr. Thomas W. Evaus, the famous American dentist, died at Paris, November 12, aged seventy-four.

Carl Eisenlohr, M.D., of Hamburg, a neuropathologist and anatomist, died in May at the Madeiras, of tuberculosis, in his fifty-first year.

C. Fumagalli, M.D., surgeon-in-chief to the Hospital Maggiore of Milan, died in September.

Rudolphe Pierre Henri Heidenhain, M.D., incumbent of the Chair of Physiology at the University of Breslau, died in October at Breslau, aged sixty-three.

John Braxton Hicks, M.D., London, F.R.C.P., F.R.S., the eminent obstetrician and gynecologist to Guy's Hospital, died on August 28, at Lymington, Eng., aged seventy-two.

Alarik Frithiof Holmgren, M.D., professor of physiology in the University of Upsala and founder of the first Physiological Institute in Sweden, died in October, aged sixty-six.

Johann Ritter von Leich, M.D., formerly dean of the medical faculty of the University of Vienna, died in July, aged eighty-four.

Jules Bernard Luys, M.D., an eminent alienist, member of the Academy of Medicine and officer of the Legion of Honor, died in September, aged sixty-nine.

Jacques Maisonneuve, M.D., the distinguished Parisian surgeon, died in May, at the age of eighty-seven.

Surgeon-Major Robert Manser, physician to the Jamsetjee Jeejeebhai Hospital and Professor of Medi-

cine in the Grant College Medical School, Bombay, died of plague in that city in June, aged forty-eight.

Victor Meyer, M.D., professor of chemistry at Heidelberg, died in that city on October 8.

Dr. Morvan, who was the first to describe the group of clinical symptoms known as "Morvan's disease," died at Lannuès, France, aged seventy-three.

M. A. Muniz, M.D., professor of medical physics and hygiene; superintendent of National Insane Asylum and chairman of the National Board of Health of Lima, Peru, died in June, aged thirty-six.

M. J. Oertel, M.D., a laryngologist, died on July 13 in Munich, aged sixty-two.

George David Pollock, F.R.C.S., consulting surgeon to St. George's Hospital, died in London in February.

Walter Rivington, M.S. Lond., F.R.C.S. Eng., consulting surgeon to the London Hospital, member of the Council of the College of Surgeons and of the Senate of the University of London, died on May 8, aged sixty-two.

James Greig Smith, M.A., M.B., C.M. (Aber.), F.R.S. (Edin.), distinguished in abdominal surgery and professor of surgery in University College, Bristol, Eng., died on May 28.

Professor Stukowenkoff, professor of dermatology and venereal diseases in the University of Kieff, died in April, aged fifty-seven.

Professor Tarnier, of Paris, the distinguished obstetrician, died in Paris in December, aged seventy.

Dr. Welcker, who was for a great number of years professor of anatomy in the University of Halle, died in August, aged seventy-five.

Sir Spencer Wells, of London, the distinguished pioneer in abdominal surgery, died at Antibes, France, in the seventy-ninth year of his age.

NECROLOGY. — UNITED STATES.

Harrison Allen, M.D., emeritus professor of comparative anatomy in the Medical School of the University of Pennsylvania, died November 14, aged fifty-six.

Charles H. Avery, M.D., for many years corresponding and recording secretary of the Medical Society of the County of New York, died November 2, aged sixty-three.

Surgeon-General Newton L. Bates, of the U. S. Navy, died at Washington, October 18.

John H. Bemiss, M.D., president of the faculty and professor of the chair of physical diagnosis in the New Orleans Polyclinic; visiting physician to the Charity Hospital of New Orleans, died of yellow fever, September 5, aged fifty.

John C. Bolles, of Montville, Conn., one of the oldest members of the New London County Medical Association, died September 11, aged eighty-one.

John O. Bronson, M.D., formerly professor of anatomy at the Sheffield Scientific School and chief medical officer of the Department of the Pacific, died at his home at Rhinebeck, N. Y., March 28, aged seventy.

Bedford Brown, M.D., a former president of the Virginia Medical Society; and of the Southern Surgical and Gynecological Association, died at Alexandria, Va., September 13, aged seventy-six.

Edward Seaman Bunker, M.D., for many years a professor in the Long Island College Hospital, Brooklyn, died June 7, aged fifty-seven.

Samuel H. Charlton, M.D., of Seymour, Ind., a former president of the Indiana State Medical Society, died January 12, aged seventy.

Robert M. Denig, M.D., at one time professor of medical jurisprudence in the Starling Medical College, and who later on became lecturer on Diseases of Children in the Columbus Medical College, died January 17, in Columbus, O.

John Evans, M.D., ex-Governor of Colorado, and formerly superintendent of the Indiana State Insane Asylum and for a time president of Northwestern University, Evanston, died July 3.

George F. French, M.D., professor of obstetrics and gynecology, Minnesota Hospital College and president of the Minnesota Academy of Medicine, etc., died at Minneapolis, Minn., July 5, aged sixty.

P. G. Frye, M.D., at one time president of the Queens County Medical Society, died at Oyster Bay, October 9, aged eighty.

A. J. Fuller, of Bath, Me., died January 10, aged seventy-four. He was first vice-president of the American Medical Association and for eighteen years president of the Bath Board of Trade.

Richard John Hall, M.D., of New York City, formerly lecturer on the principles of surgery at New York College of Physicians and Surgeons, died January 24, at Santa Barbara, Cal., aged forty-one.

Henry Hartshorne, M.D., at one time professor of practice of medicine and later professor of hygiene in the University of Pennsylvania, died at the age of seventy-three, at Tokyo, Japan, February 10.

Archibald A. Higgins, M.D., a leading physician and former judge of Monmouth County, N. J., died at his residence at Mauasquan, N. J., October 9, aged seventy.

Peter Dirck Keyser, A.M., M.D., formerly professor of ophthalmology and dean of the faculty of the Medico-Chirurgical College of Philadelphia, died October 9, aged sixty-two.

Edwin M. Kitchell, M.D., assistant professor of histology and pathology in the College of Physicians and Surgeons, New York, died in September.

Cornelius Kollock, M.D., a former president of the South Carolina Medical Association in 1887; and of the Southern Surgical and Gynecological Association, died in Cheraw, S. C., August 16, aged seventy-three.

John J. H. Love, M.D., of Montclair, N. J., a brigade surgeon-in-chief in the Army of the Potomac in 1863, died on July 20.

William Thompson Lusk, M.D., LL.D., professor of obstetrics in Bellevue Hospital Medical College, a visiting and consulting physician of many hospitals and author of "The Science and Art of Midwifery," died in New York City, June 12, aged fifty-nine.

Perry H. Millard, M.D., of St. Paul, Minn., dean of the College of Medicine and Surgery at the Minnesota State University, died on February 1 at Baltimore.

Robert B. Morrison, M.D., of Baltimore, dermatologist at Johns Hopkins Hospital and formerly president of the American Dermatological Association, died suddenly September 30.

Byron W. Munson, M.D., formerly superintendent at the State Soldiers' Home at Noroton, died at Sharon, Conn., January 2, aged fifty-three.

William H. Pancoast, M.D., of Philadelphia, formerly professor in the Jefferson Medical College and later president of the Medico-Chirurgical College in Philadelphia, died January 8, aged sixty-two.

Luke Robinson, M.D., an ex-president of the State Medical Society of California, died October 10.

James Simpson, M.D., of San Francisco, Cal., a former president of the State Board of Health of California, died October 22, aged seventy-one.

Julius A. Skilton, M.D., who was an army surgeon during the Civil War and Consul-General in the City of Mexico under General Grant, died in Brooklyn, November 20.

Job Lewis Smith, M.D., clinical professor of Diseases of Children in Bellevue Hospital Medical College, died in New York, June 9, aged seventy.

Anthony Eugene Stocker, M.D., for many years on the surgical staff of the Pennsylvania Hospital, died May 23, in Philadelphia, aged seventy-eight.

George Thomas, M.D., professor of laryngology and physical diagnosis at the College of Physicians and Surgeons, Baltimore, died in October, aged thirty-eight.

Benjamin H. Throop, M.D., of Scranton, Pa., one of the founders of Scranton and of the Lackawanna Hospital, died June 26, aged eighty-six.

Geo. B. Twitchell, M.D., of Keene, N. H., one of the leading practitioners of New Hampshire, who was during the war surgeon of the 13th New Hampshire Volunteers and was promoted surgeon-in-chief of the 17th corps, with the rank of major, died at Keene, March 30. He was for years president of the board of trustees of the New Hampshire Asylum for Insane, and was instrumental in the establishment of the Elliot Hospital in Keene.

James P. Walker, M.D., assistant surgeon nearly a year on the medical staff of the Fourth New Hampshire Volunteers and for a number of years member of the Board of Education and the Legislature, died in Manchester, N. H., May 6, aged sixty-nine.

Dulaney L. Washburne, M.D., of Louisville, professor of anatomy in the University of Louisville, died in March, aged forty-two.

William C. Wey, M.D., for many years Health Officer of Elmira, N. Y., and a former president of the New York State Medical Society and of the Board of Managers of the New York State Reformatory, died June 30.

H. P. C. Wilson, M.D., a former vice-president of the American Gynecological Society, died in Baltimore, December 27, aged seventy.

Theodore G. Wormley, M.D., professor of chemistry and toxicology in the medical department of the University of Pennsylvania, died April 3, aged seventy-one.

NECROLOGY. — MASSACHUSETTS MEDICAL SOCIETY.

Edward Payson Abbe, M.D., M.M.S.S., died in New Bedford, February 25, aged sixty-nine.

William Shepherd Beaumont, M.D., M.M.S.S., died in Jamaica Plain, January 7, aged thirty-one.

Henry Blanchard, M.D., M.M.S.S., died in Neponset, February 10, aged eighty-five.

Joseph Jackson Boynton, M.D., M.M.S.S., died in South Framingham, June 17, aged sixty-four.

George Washington Burdett, M.D., M.M.S.S., died in Clinton, May 10, aged seventy-eight.

Frank Bowditch Chapman, M.D., M.M.S.S., died in Middleton, June 11, aged twenty-nine.

Charles Edward Clark, M.D., M.M.S.S., died in Lynn, October 29, aged fifty-six.

Charles Wendell Cooper, M.D., M.M.S.S., of Northampton, died at sea, February 7, aged forty-five.

Benjamin Eddy Cotting, M.D., M.M.S.S., died in Roxbury, May 22, aged eighty-four.

Joseph Whitney Cushing, M.D., M.M.S.S., died in Brookline, May 3, aged sixty.

William Baxter Cushman, M.D., M.M.S.S., died in Oxford, February 25, aged forty.

Charles Henry Davis, M.D., M.M.S.S., died in Worcester, September 16, aged fifty-one.

John Osborn Dow, M.D., M.M.S.S. died in Reading, February 22, aged seventy-four.

Edward Pearson Elliot, M.D., M.M.S.S., first assistant in the Danvers Insane Hospital, died January 10, aged forty.

Thomas Joseph Hayes, M.D., M.M.S.S., died in Beverly, August 26, aged thirty-five.

Samuel Hutchins Hurd, M.D., M.M.S.S., formerly of Charlestown, died at Atlantic City, N. J., February 5, aged sixty-six.

Daniel March, Jr., M.D., M.M.S.S., of Winchester, died in Woburn, January 1, aged fifty-two.

Frederic Joseph McNulty, M.D., M.M.S.S., died in Roxbury, June 13, aged sixty-two.

Ira Loriston Moore, M.D., M.M.S.S., died in Boston, October 2, aged seventy-two.

Varillus Linus Owen, M.D., M.M.S.S., died in Springfield, September 7, aged seventy-two.

Asa Flanders Pattee, M.D., M.M.S.S., died in Boston, May 31, aged sixty-two.

John James Savage, M.D., M.M.S.S., died in Lowell, January 12, aged twenty-four.

Charles A. Stark, M.D., M.M.S.S., died in Marshfield, January 22, aged thirty-five.

Isaac Holden Stearns, M.D., M.M.S.S., died in Cliftondale, September 6, aged seventy-two.

William Henry Thayer, M.D., M.M.S.S., died in Lauesborough, December 22, aged seventy-five.

Eben Thompson, M.D., M.M.S.S., died in Newton Upper Falls, December 7, aged forty-nine.

Frederick Moncrieff Turnbull, M.D., M.M.S.S., died in Cambridge, January 15, aged forty-three.

George Webb West, M.D., M.M.S.S., died in Chestnut Hill, Newton, August 5, aged forty-seven.

Edward Augustus Welch, M.D., M.M.S.S., died in Sutton, November 9, aged thirty-two.

William Goodnough Wheeler, M.D., M.M.S.S., died in Chelsea, April 17, aged seventy-six.

Fred. Webster Whittemore, M.D., M.M.S.S., died in Cambridge, April 14, aged forty-five.

Thomas Womersley, M.D., M.M.S.S., died in Wattertown, March 7, aged eighty-one.

During the year 1897 thirty-two members of the Society have died, two less than in the preceding year. The average age was fifty-six years, that of 1896 having been fifty-seven and one-half years, and of 1895, sixty-six years. Three were over eighty years of age, nine were seventy or over. The lowest age of death was twenty-four and the highest eighty-five.

MEDICAL NOTES.

CIGARETTE SMOKING AS A CAUSE OF DEATH.—A coroner at Felling, near Gateshead, Eng., has brought in a verdict as a result of an inquest on the body of a sixteen-year-old lad, to the effect that he died from "syncope due to nicotine poisoning, caused by the excessive smoking of cigarettes." The coroner also stated that there was quite an epidemic of deaths from this cause. A careful exclusion of other causes would seem to be essential to the establishment of the truth of this somewhat improbable statement.

MEDICAL PERIODICALS IN THE UNITED STATES.—We find, from a newspaper directory recently issued, that the medical profession of that country supports directly or indirectly 275 periodicals, of which 10 are issued weekly, 11 fortnightly, 225 monthly, 6 bi-monthly, and 23 quarterly, with a combined yearly circulation of 16,017,200 copies. Estimating that there are in round numbers 120,000 medical men of all schools north of the Gulf of Mexico, of whom probably not over 80,000 subscribe to a medical journal of any kind, this vast amount of literature seems an enormous burden to carry. — *Health*.

THE BACILLUS OF EBERTH IN WATER, EARTH AND FECES OF NON-TYPHOID PATIENTS.—Remlinger and Schneider (*Compt. Rend. de la Soc. de Biol.*, 1896, No. 26; *Centralblatt f. Innere Medecin.*, No. 43) claim by means of Elsner's method to have isolated in 8 out of 36 specimens of water, in 6 out of 10 specimens of soil, and in the feces of three patients suffering from tuberculosis, malaria and nephritis, who had never had typhoid fever, a bacillus which presented all the characteristics of the typhoid bacillus, upon which typhoid serum produced its specific reaction, and which caused the death of 12 out of 18 guinea pigs inoculated with it. If the guinea-pigs had received a preventive inoculation of one cubic centimetre of typhoid serum, they invariably recovered.

NEW YORK.

SMALL-POX AT QUARANTINE.—The steamer *Edam*, which on December 19th arrived from Amsterdam and Boulogne, was found to have small-pox on board, and by order of Health Officer Doty 275 steerage passengers were vaccinated and transferred for observation to the quarantine station on Hoffman Island, where they will have the pleasure of enjoying Christmas and New Year's dinners at the expense of the steamship company.

DEATH FROM PHENACETINE POISONING.—A death from phenacetine occurred on December 23d.

A patient suffering from influenza who was ordered by his attending physician a six-grain tablet of the drug every two hours, swallowed all the tablets prescribed at once. The total amount of phenacetine taken is not given. The patient was a young man twenty-three years of age.

FATAL CLUBBING BY POLICEMEN.—Two policemen have lately been arraigned for clubbing patients over the head with fatal results. One of the victims died at Roosevelt Hospital on November 28th, from a fractured skull, and the other at Bellevue on December 14th, of acute meningitis complicated with erysipelas.

THE USELESSNESS OF THE CORONER.—The Kings County Grand Jury for December, in its presentment made to Judge Hurd, of Brooklyn, on December 23d, recommends the Legislature to abolish the office of coroner. "We believe," it states, "the office is useless; that it has no practical effect in the ferretting out of crime; that the methods in vogue are open to the most severe censure; that the continuance of the office in its present shape, as the law now stands, will lead to further abuses; that the law governing the rights, duties and obligations of the coroner is not clear or specific."

RECORD OF MORTALITY
